Army Service Corps (renamed Royal Army Service Corps on Nov. 27 1918).—From 1910 until the close of the war extensive development and expansion of the Army Service Corps took place, the former being a process of slow evolution during the four years preceding the outbreak of war; the latter being necessarily rapid, and the direct result of the war itself. The strength of the corps in 1914 was 498 officers and 5,933 men; and on Armistice Day 1918 it had grown to 11,564 officers and 314,824 men. The creation of the new armies in 1914 necessitated a large and rapid increase of Army Service Corps officers; and a number of "direct" temporary commissions were granted to applicants whose experience in civil life was such as to fit them for the miscellaneous duties of the corps. The numbers obtained were so great that transfer to the fighting arms was encouraged, and later, for younger men, insisted on. The transfers totalled 1,200. Similar steps were taken as regards other ranks—82,000 being replaced in the Army Service Corps by men of other services who had become unfit for the trenches, by women and by coloured personnel. The sub-division of the duties of the Army Service Corps into animal transport, mechanical transport, and supplies continued. As regards animal transport, although the period from 1910 to 1914 showed a decrease, owing to the gradual introduction of mechanical propulsion, the expansion of animal transport during the late war was both colossal and varied, in that horses, mules, camels, donkeys, bullocks, reindeer, and dogs were all utilized to meet the divergent requirements of the various theatres. In France the Army Service Corps were responsible for the provision of personnel and the upkeep of all divisional trains, reserve parks, auxiliary horse transport companies, and horsed ambulances; and they even extended their scope in that in their advanced horse transport depots, in addition to maintaining their own formations, they held complete turn-outs for every arm of the service, technical and non-technical. In Egypt and Palestine, in addition to extensive employment of normal horsed transport, 40,000 camels and 8,000 donkeys were used. In E. Africa also, as far as animal transport was possible in that theatre (owing to tsetse), in addition to the horsed transport, bullock transport and carrier transport were largely used; and in north Russia the horse and mule were largely substituted by reindeer and dogs drawing sleighs. The outstanding feature, prior to the war, was the growth of mechanical transport, and during the war the intensive use of the internal-combustion engine in place of steam propulsion. The expansion of the mechanical-transport branch of the Army Service Corps can best be appreciated by the fact that in 1910 the total number of mechanical vehicles was approximately 175; in 1914, 248 four-wheeled vehicles and 24 motor-cycles; and in 1918, 86,837 four-wheeled vehicles and 34,865 motor-cycles. Concurrently with the large increase in vehicles, a corresponding development had of necessity to take place to ensure their maintenance. Mobile repair units were established in the field, light repair shops in the advanced areas and heavy repair shops at the bases. Advanced mechanical-transport store depots were likewise formed in the forward areas, also main mechanical transport depots at the bases. At the commencement of the war a portion of the large number of vehicles required were obtained through the medium of a subsidy scheme during peace, but, as the subsidy scheme was in its infancy, the major portion had to be obtained by impressment, the result being that vehicles were a heterogeneous collection of condition and makes. The resources of the United Kingdom were developed to their maximum, and had of necessity to be supplemented largely through purchases abroad. Every endeavour was made to standardize the vehicles in each formation, and to eliminate non-standard makes at the earliest possible date; and the efficiency of the mechanical transport was largely due to the thoroughness with which this was carried out. In the case of supplies, prior to the war the soldier at home received a daily issue of bread and meat only, the remaining items comprising his ration being provided by means of a daily cash allowance expended under regimental arrangements. On the outbreak of war the troops both at home and abroad passed automatically to the "field" scale of rations, and the Army Service Corps was at once responsible for the provision and distribution of all the items comprised therein, as well as for many categories of medical comforts for hospital use, and, in addition, the provision of forage and petrol. As the armies increased in size, and included many different nationalities among their personnel, special treatment in diet was required, so that a remarkable diversity of commodities had to be provided; the number of these at the cessation of hostilities amounted to approximately 500 different articles, mostly perishable, as com-

pared with about 60 in 1914. During the war daily feeding strengths in all theatres reached approximately 5,400,000 men and 867,000 animals, and to meet these numbers the daily tonnage in foodstuffs was 11,000 tons, and in forage 8,000 tons. To ensure this maintenance, supplies were drawn from every quarter of the globe, a fact which—combined with the effects of submarine warfare—necessitated provision being made months ahead, so that a steady flow to the various theatres of war should continue with the minimum of interruption. Further, it was necessary to establish large bakeries, build frozen-meat stores, or increase the existing accommodation for frozen meat, and develop the local resources of each theatre to the fullest extent, with the view of economizing shipping. The Army Service Corps also undertook the manufacture of certain commodities, such as pearl barley, sausages, beef stew, tibben, jam, ghi, and tinned chicken; in addition to agricultural developments for the provision of vegetables, potatoes, barley, maize and wheat. They also arranged bulk installations for petrol, and the necessary provision of tinplating and case-boarding for canning and packing.

Army Ordnance Services.—In 1910, and onwards till 1914, the ordnance services of the army were carried on by a staff of 251 officers and 2,341 other ranks, reënforced by some 4,300 civilian subordinates. The "other ranks" were formed in 9 companies of widely varying strengths, and in a number of small detachments distributed throughout the army. The holding of bulk supplies of ordnance stores and clothing was restricted to Woolwich and Pimlico respectively. To these two places were consigned the stores and clothing manufactured or supplied by the Government factories or the trade, and from them distribution was made to the local ordnance depots for issue to the troops. Reserves of warlike stores and clothing for one cavalry division, one cavalry brigade and 6 infantry divisions were held in ordnance charge at Woolwich, Pimlico or elsewhere together with mobilization equipment for those units which, while non-existent in peace-time, would be required to place the Expeditionary Force on a complete war footing. As regards the organization of the ordnance services for war, this was almost exclusively confined to functions on the lines of communication. The personnel allotted to the frontal area was limited to a deputy director (and a small staff) with Expeditionary Force headquarters, a deputy-assistant director with each division, and a warrant officer with each brigade. The director of ordnance services was to be on the staff of the I.G.C. lines of communication. The personnel for lines-of-communication duties was to be found by forming ordnance companies each with an establishment of 2 officers and 164 other ranks, additional officers being allotted according to the number of companies mobilized. When, in Aug. 1914, the Expeditionary Force embarked for France, 8 of these ordnance companies with 32 additional officers accompanied it to the bases, where were also dispatched the war reserves of stores and clothing. The rapid expansion of the army in the field, and the multiplication of various expeditionary forces in widely separated parts of the globe, not only called for great increases in ordnance personnel but also revolutionized the organization of the services in the field. The main alteration lay in the recognition of the necessity for extending the principle of an ordnance officer with a division to an ordnance organization with the headquarters of each corps and army. Moreover, the immense use made of artillery throughout the campaign called into existence a number of mobile ordnance workshops, the main functions of which were to bridge the gap between the artillery front and the large workshops at the base. These field workshops, which were all mechanically propelled or drawn, were of three categories, light, medium and heavy, their nomenclature indicating the nature of the repairs to be undertaken, as also their relative degree of mobility. Though frequently "pooled" to meet any particular set of circumstances, they were organized on a scale of two light per three divisions, one medium per corps and one heavy per army. The value of these mobile shops will be the better appreciated when it is stated that but for them something like 45,000 guns and carriages would have had to be relegated some distance to the rear, if not to the base, for repair.

At the date of the Armistice there were in existence 60 of the light, 25 of the medium and 6 of the heavy variety. Other novel formations at the front included gun parks, railhead detachments, ammunition sections, and officers' clothing depots, while there were added to the normal organizations on the lines of communication institutions such as schools of instruction in ammunition, ammunition repair factories and repair depots at the bases. The effect of this wide expansion of ordnance functions and of the magnitude of the operations in the different theatres of war was to call for a very great increase in personnel, both officers and men. In the case of the former, employment was from the commencement offered to retired officers who, by taking over the work at home, released the active officers for service abroad. As soon as it was seen that many more officers would be required, a scheme was set on foot to obtain "temporary" officers from suitable professions in civil life, and to train them in ordnance duties. As for the other ranks, large numbers of pensioned warrant and non-commissioned officers of the corps offered their services, the remainder required being obtained by direct enlistment. At the date of the Armistice 2,342 officers and 38,193 other ranks were doing duty with the ordnance services, in 144 companies and other formations. The majority of this personnel was serving overseas; the balance were at the home depots, where they formed the nucleus of a mass of civilian labour, which reached a maximum of 48,000, nearly one-half being women.

Turning to the store side of the question, the original war reserves were early exhausted, and it became necessary to evolve storage schemes in this country of far wider dimensions than were offered by the original depots at Woolwich and Pimlico. Each of these parent institutions set up subsidiary depots up and down the country, as far as possible devoting each to the storage of the class of article supplied by the trade of the particular locality. From these sub-depots supplies in bulk were sent overseas direct as ordered, thus materially reducing transport and double handling. Moreover, inspection hitherto carried out only at the respective headquarters was decentralized so as to enable inspection to take place either at these sub-depots or at contractors' works. In addition to these expansions an entirely new depot of very large capacity was erected at Didcot and worked independently of Woolwich. A separate organization was called into existence to deal with the vast quantities of ammunition and explosives turned out by the national filling factories. A number of "dumps" were formed in various parts of the kingdom, and in addition an ordnance depot was attached to each factory and took over its daily output for dispatch as ordered. Some idea of the magnitude of the task imposed upon the ordnance services can be had when it is stated that the following quantities of the items named were dealt with:—6-inch (and larger) guns, 5,756; 60-pounder guns (and under), 21,160; machine-guns, 230,000; gun-ammunition rounds, 217,000,000; small-arm-ammunition rounds, 9,150,000,000; blankets, 40,674,773; personal equipment sets, about 6,500,000; jackets, upwards of 27,000,000; trousers, 27,000,000 pairs; pantaloons, 8,000,000 pairs; boots, 40,000,000 pairs.

Labour.—The density of armies—*i.e.* the number of men to the acre in the area of active operations—increased to a degree never imagined in previous wars; and this, with the long period of static warfare and the introduction of mechanical transport, by which alone it was possible to cope with the movement of the vast amount of ammunition, stores and supplies required, made road maintenance of paramount importance. The need for personnel to create and maintain the road communications became so acute that, in June 1915, labour battalions of navvies were formed. At first all the personnel was over military age, and 11 battalions attached to the Royal Engineers were formed; but these, together with the Army Service Corps companies which had gradually become necessary for work in the docks and stores, were all transferred *en bloc* to the Labour Corps in 1917. In this year also the importation of coloured labour, including Chinese and S. African, was introduced. When the French railways became so congested as to be on the verge of a breakdown, this Labour Corps was augmented from every possible source, and a large number of companies of prisoners-of-war were affiliated with it. The basis of organization was the company of 500 men; the total personnel actually raised for labour purposes being approximately 900,000, including 95,000 Chinese. In addition to the requirements for the theatres of operations, smaller companies, known as Agricultural Companies, composed of unfit and over-age men, were formed to assist agriculture at home.

Expansion.—No plan existed in 1914 for the expansion of the regular forces, beyond the automatic embodiment of the special reserve units. These were already included in the scheme for Home Defence, with the exception of certain extra-special reserve units which were earmarked for other service. The only step taken towards expansion during the mobilization period was to withdraw prior to embarkation 3 officers and 8 non-commissioned officers from each infantry unit of the Expeditionary Force. The next step was to call home regular units from overseas garrisons, relieving them by extra-special reserve units and territorial units who volunteered for the duty. These regular units on arrival from overseas were reorganized. The additional mounted brigades thus formed, with existing available mounted troops, enabled the cavalry to be reorganized as a corps of 3 divisions, each of 4 cavalry brigades. The 5 additional infantry divisions were completed as to other arms by the mobilization of artillery and engineer units existing at home surplus to the Expeditionary Force; but horse artillery and fortress engineer companies had to be used in some instances to make good deficiencies.

Lord Kitchener, on assuming control as Secretary of State for War, at once grasped the need for immediate and immense expansion, but there remained no regular army basis on which to build, and three alternative courses presented themselves: (*a*) To expand the special reserve, which was partially regular owing to the inclusion of the regular depot establishments; (*b*) to use the Territorial Force organization, which provided a framework of 14 mounted brigades and 14 infantry divisions; (*c*) to

create entirely new formations. The objections to the first course were that it would disorganize the maintenance organization (the special reserve) of the regular forces already engaged in the campaign, that the number of special reserve units was too small and that they consisted of practically nothing but infantry. The main objection to the second was the inadequacy of the framework upon which to construct the necessary 100 infantry divisions; duplication and reduplication of these small nuclei would eventually entail practically new formations; their duplication and reduplication for dilution by the inclusion of the untrained manhood of the country would render them immobile and temporarily disorganize them for any purpose whatsoever. Home Defence would thereby be paralyzed and the possibility of using any units already existing and organized for reënforcements would be neutralized. Lord Kitchener therefore decided to create new divisions forthwith, retaining the special reserve for its maintenance functions and simultaneously fostering the training and recruiting (and eventual duplication) of the Territorial Force in order to relieve regular army units in garrisons overseas and to supply immediate unit reënforcements to the field army; and further, as soon as the territorial divisions, not broken up for the above two purposes, were sufficiently trained, to put them into the field as complete divisions. The new divisions were to be created as armies (popularly termed Kitchener armies), each of 100,000 men; and the nucleus of the I. New Army was at once commenced by forming the unit organization of 6 divisions (numbered 9 to 14) and drafting into them the necessary personnel. The II. and III. Armies began to form in Sept. 1914 and comprised the divisions numbered 15, 17, 18, 19, 20, 21–26 and 37. The IV. Army (30th to 35th Divs.) began to form in Oct. and Nov. but never took the field in divisions, being converted in April 1915 to draft-finding duties. The V. Army (Divs. 16, 36, 38, 39, 40 and 41), begun in Dec., eventually took the divisional numbers of the IV. Army. The Territorial Force divisions used to relieve regular troops overseas were the 1st Wessex, 1st Home Counties and 2nd Wessex. These were never re-formed as divisions. Units of the W. Lancs. and 1st London Divs. used as unit reënforcements to the Expeditionary Force in France, were eventually reassembled in their divisions there. Those who took the field later as complete formations did so at first under their territorial designations but were eventually numbered so that the final divisional enumeration of the Field Army Divisions included all regular, territorial, New Army, Indian (embracing British and Indian native units) and Dominion contingents.

Recruiting During the War.—With the exception of a certain number of officers (who had had experience in the army and in many cases experience of minor campaigns) and of a certain number of older men whose period of army and reserve service had expired, there existed no reservoir of men who had undergone regular military training to arms, owing to the fact that the army had always been maintained by voluntary enlistment. This was a considerable handicap; but, on the other hand, the fact that a number of ex-officers and older men had had previous campaigning experience was an advantage, though, of course, they were insufficient in numbers to deal with the man-power of the nation as a whole.

Directly mobilization was ordered voluntary recruits offered themselves in such numbers that the recruiting machine was for a time paralyzed and unable to deal with the applicants. The intake, which, prior to the outbreak of war, was from 70 to 80 per day, rose immediately to 6,000 per day from Aug. 5 to 22; to 9,000 per day from Aug. 22 to 30; and by Sept. 3 it had reached 33,000 per day. On Sept. 10, owing to lack of accommodation in barracks and deficiencies in stores and equipment, the standards had to be raised considerably. This was correctly interpreted as meaning that the urgent need for men was over; and the numbers fell to 2,500 per day. On Nov. 6 the standard was again lowered, and recruiting rose to 3,000 a day.

Towards the end of the year—when it became evident that more men would be required—a parliamentary recruiting committee was formed, and a recruiting campaign was undertaken throughout the country, resulting in an intake of some 60,0
men. In July 1915, a National Registration Act was passe
and the Local Government Board were allotted the task
supplying the particulars of all males between the ages of
and 41. From these, registers were compiled in various recrui
ing areas; and in Oct. 1915, the "Derby Scheme" or "Gro
System" was initiated by Lord Derby on his appointment
Director-General of Recruiting. Under this system men we
to be enlisted for one day and immediately passed into t
reserve with liability to be called to the Colours when require
Between Oct. 25 and the middle of Dec. 2,000,000 men we
attested under this system, of whom 50% were married me
but as the Government had given a pledge that single men wou
be called up before married men, and it became clear that t
single men of the nation had not responded, it was decided
introduce compulsory service.

The first Military Service Act received the royal assent at t
end of Jan. 1916, rendering liable for military service all sin
men between the ages of 18 and 41; and calling to the Colo
under this Act commenced on March 3. The Act was la
extended to include married men, who began to be called
on June 24. Complaints were rife against the decisions of t
examining medical officers; and medical boards were substitut
in May 1917. This was followed by the transfer of recruiti
from the military to the civil authorities and the creation of t
Ministry of National Service as a civil authority for recruiti
This new ministry took over all recruiting duties for the na
army and air force on Nov. 1 1917. A further Military Servi
Act was introduced in April 1918, rendering liable for milita
service all men between the ages of 18 and 51; but in act
practice the calling-up of the older men produced small resul

Under the authority of the War Office 2,631,313 men vol
tarily enlisted between Aug. 4 1914 and the end of Feb. 19
and from March 1 1914 to end of Oct. 1917, 1,790,381 men w
called to the Colours; this gives a total of 4,421,694. Sub
quently, under the authority of the Ministry of National Servi
from Nov. 1 1917 to the Armistice (Nov. 11 1918) 549,208 m
were called to the Colours. After the Armistice enlistm
again became voluntary, and the ministry enlisted 1,138 m
into the regular army up to Jan. 15 1919, when recruiting w
retransferred to the War Office.

Higher Formations by Theatres of War.—The gradual exp
sion of the British armies in the various theatres, and variati
in the strategical situation, led to changes in the organization
higher commands and to movements of the minor formati
from one theatre to another. It is only necessary here to d
with the changes in organization of the higher comman
theatre by theatre.

France (and United Kingdom).—The first Expeditionary Fo
was organized as one army, sub-divided into 3 army corps. T
I. and II. Army Corps and cavalry division took their place on
left of the French army in Aug. 1914, and fighting had commen
before the arrival of the 4th Div. and the III. Army Corps he
quarters to which this division was allotted. These, however, to
part in the operations from Le Cateau onwards, the 19th I
Bde. (composed of battalions originally allotted to the lines
communication) for the time being taking the place in the I
Army Corps of the 6th Div., which did not join the army in the fi
until the middle of September. The army was commanded
Field-Marshal Sir J. D. P. French, with Lt.-Gen. Sir A. J. Mur
as chief of the general staff, Lt.-Gen. Sir C. F. N. Macready
adjutant-general, Lt.-Gen. Sir W. R. Robertson as quartermast
general, and Maj.-Gen. Sir F. S. Robb as inspector-general of
lines of communication. The I. Army Corps was commanded
Lt.-Gen. Sir D. Haig, and was composed of the 1st and 2nd Divisio
The II. Army Corps—originally commanded by Lt.-Gen. Sir J.
Grierson, who died in France *en route* to the position of assembl
was commanded by Gen. Sir H. L. Smith-Dorrien, and was co
posed of the 3rd and 5th Divisions. The III. Army Corps w
commanded by Lt.-Gen. W. P. Pulteney, and was composed of
4th and 6th Divisions. The cavalry division was commanded
Maj.-Gen. E. H. H. Allenby.

In Oct. 1914 the 7th Div. and the 3rd Cav. Div. landed at Oste
under the command of Maj.-Gen. Sir H. S. Rawlinson.

By Nov. 1914 the cavalry had been expanded to a corps of th
divisions under Lt.-Gen. Allenby. Two Indian cavalry divisi
composed of British and Indian units arrived shortly afterwa

The remainder of the army was organized as follows:—I. Army Corps (Haig), II. Army Corps (Smith-Dorrien), III. Army Corps (Pulteney), IV. Army Corps (Rawlinson), Indian Army Corps (Lt.-Gen. Sir J. Wilcocks). There was shortly added the V. Army Corps (Gen. Sir H. C. O. Plumer). The Expeditionary Force had now attained dimensions which necessitated its further sub-division, and the term "Army" was introduced on Dec. 26 1914, after which the army corps were designated "Corps." General Sir Douglas Haig was appointed to command the I. Army and Gen. Sir H. Smith-Dorrien, who was shortly succeeded by Gen. Sir H. C. O. Plumer, the II. Army. Lt.-Gen. Sir W. R. Robertson became chief of the general staff in France in Jan. 1915, and Lt.-Gen. R. C. Maxwell succeeded him as quartermaster-general. The III. Army was formed in July 1915, and Gen. Sir C. C. Monro appointed to the command; he was succeeded by Gen. Sir E. H. H. Allenby, in Oct., on his appointment to the command-in-chief in the Dardanelles.

In Oct. 1915 the composition of the British armies was: G.H.Q. troops; Royal Flying Corps (Trenchard) in three wings; Cavalry Corps (Bingham) of three divisions; I. Army (Haig)—I. Corps (H. Gough), III. Corps (Pulteney), IV. Corps (Rawlinson), Indian Corps (C. B. Anderson); II. Army (Plumer)—II. Corps (Fergusson), V. Corps (H. D. Fanshawe), VI. Corps (Keir); III. Army (Monro, then Allenby)—two Indian cavalry divisions (Barrow and Cookson), VII. Corps (Snow), X. Corps (Morland), Canadian Corps (Alderson), XI. Corps (Haking).

On Dec. 19 1915 Gen. Sir Douglas Haig succeeded Field-Marshal Sir John French in command of the British armies in France, and Lt.-Gen. L. E. Kiggell became chief of the general staff. In Feb. 1916, Lt.-Gen. G. H. Fowke became adjutant-general. Field-Marshal Sir J. French was appointed commander-in-chief of the Home Forces.

In Dec. 1915 the reorganization of the War Office staff at home, necessitated by the enormous expansion of the British army and the increasing number of theatres of war, caused considerable changes. Lt.-Gen. Sir W. Robertson succeeded Lt.-Gen. Sir A. J. Murray, as C. I. G. S. Lt.-Gen. Sir C. F. N. Macready succeeded Lt.-Gen. Sir H. C. Sclater as adjutant-general to the forces in Feb. 1916. Lt.-Gen. Sir J. Cowans continued as quartermaster-general to the forces—a position which he had occupied since the commencement of the war and which he held until the end. In Feb. 1916 Gen. Sir C. C. Monro took command of the I. Army in France.

In Sept. 1916 the British Expeditionary Force in France continuing its expansion was reorganized into five armies, comprising: G.H.Q. troops; Royal Flying Corps (Trenchard) in five brigades; I. Army (Monro, then Horne)—I., IV., XI. Corps, totalling 10 divisions; II. Army (Plumer)—VIII., IX., I. Anzac, II. Anzac Corps, totalling 13 divisions and including 1st, 2nd, 4th and 5th Australian and 4th Canadian Divs.; III. Army (Allenby)—2nd Cav. and 1st (Indian) Cav. Divs., VI., VII., XVII. Corps, totalling 1 cavalry division and 6 divisions; IV. Army (Rawlinson)—1st Cav. and 2nd (Indian) Cav. Divs., III., X., XIV., XV. Corps, totalling 2 cavalry divisions and 17 divisions (including the Guards and New Zealand Divs.); Reserve (later V.) Army (Gough)—3rd Cav. Div., II., V., XIII. and Canadian Corps, totalling 1 cavalry division and 10 divisions.

In Oct. 1916 Gen. Sir C. Monro was appointed commander-in-chief in India and was succeeded in command of the I. Army by Gen. Sir H. S. Horne. In June 1917 Gen. Sir E. H. H. Allenby was appointed commander-in-chief in Egypt and Palestine, and was succeeded in command of the III. Army by Gen. Sir J. H. G. Byng.

In Aug. 1917 the organization of five armies still held good. The Cav. Corps had been reconstituted, and comprised the 1st, 2nd, 3rd and 5th Cav. Divs.; the Indian units of the Indian cavalry divisions having been transferred to Egypt and Palestine, and the remainder of the cavalry—reënforced by mounted yeomanry—having been reorganized into the above divisions. The I. Army (Horne), containing the I., XI, XIII., Canadian and Portuguese Corps, totalled 13 divisions—the 4 Canadian divisions being now in one corps and the 2 Portuguese divisions which had joined the Allies being organized with the British forces. The II. Army (Plumer) comprised the IX., X., I. Anzac and II. Anzac Corps, totalling 12 divisions; the 1st, 2nd and 5th Australian Divs., constituting the I. Anzac Corps and the 3rd and 4th Australian Divs., with the New Zealand Division, the II. Anzac Corps. The III. Army (Byng) comprised the III., IV., VI., VII., and XVII. Corps and the 4th Cav. Div.—totalling 1 cavalry division and 15 divisions. The IV. Army (Rawlinson) temporarily comprised only the XV. Corps of 4 divisions, and the 1st Div., not incorporated in a corps. The V. Army (Gough) comprised the II., V., VIII., XIV., XVIII. and XIX. Corps.

In Nov. 1917 Gen. Sir H. Plumer was appointed to command the British troops in Italy, and Gen. Sir H. Rawlinson was transferred from the command of the IV. Army to that of the II. until within a fortnight of Gen. Plumer's return in March 1918. General Sir H. Rawlinson was, in Feb. 1918, appointed British military representative on the Supreme War Council (recently instituted) and a member of the Army Council. In March, however, he was recalled to command the V. Army in the crisis following the German offensive of March 21, and in the following month resumed command of the IV. Army. In Dec. 1917 Lt.-Gen. Sir T. E. Clarke was appointed quartermaster-general, and in Jan. 1918 Lt.-Gen. Sir H. A. Lawrence chief of the general staff in France.

In Feb. 1918 Lt.-Gen. Sir H. H. Wilson was appointed chief of the imperial general staff at the War Office, and Gen. Sir W. Robertson shortly afterwards replaced Field-Marshal Viscount French (on the latter's appointment as viceroy of Ireland) as commander-in-chief in Great Britain. In Sept. 1918 Maj.-Gen. Sir G. M. W. Macdonogh succeeded Gen. Sir C. F. N. Macready as adjutant-general to the forces at the War Office, on the latter's appointment as chief commissioner of the metropolitan police.

In Aug. 1918 there were still five armies, the cavalry corps having been reduced to the 1st, 2nd and 3rd Divs., and the XIV. and XVIII. Corps broken up. These changes were due to the diminished personnel available. The composition of the divisions, too, had been weakened by the reduction of infantry brigades to 3 instead of 4 battalions. The Royal Flying Corps (now designated "The Royal Air Force") in France had been increased by the creation of the Independent Air Force (Trenchard), which took up positions in rear of the French and was concerned with long-distance bombing.

At the time of the Armistice on Nov. 11 1918 the order of battle comprised: G.H.Q. troops; Royal Air Force (T. M. Salmond), Headquarters Squadron and 9th Bde. (directly under G.H.Q.), with the 8th Bde. in the Independent Air Force (Trenchard); Cavalry Corps (Kavanagh) of three divisions; I. Army (Horne)—VII., VIII., XXII. and Canadian Corps, and 1st Bde., R.A.F.; II. Army (Plumer)—II., X., XV., XIX. Corps and 2nd Bde., R.A.F.; III. Army (Byng)—IV., V., VI., XVII. Corps and 3rd Bde., R.A.F.; IV. Army (Rawlinson)—IX., XIII. Australian Corps and 5th Bde., R.A.F.; V. Army (Birdwood)—I., III., XI., Portuguese Corps and 10th Bde., R.A.F.

After the conclusion of the Armistice the bulk of the armies were demobilized or transferred home, the remainder forming, with young soldier battalions from home, the army of the Rhine and the necessary clearing-up forces in France and Belgium.

Italy.—In Nov. 1917, in the crisis following Caporetto, British and French reënforcements were sent from France. The British troops were allotted the Montello sector of the defence of the Piave, which was the hinge linking the portion of the line facing N. in the Alps with that facing E. in the plain and covering Venice. General Sir H. Plumer, until then commanding the II. Army in France, was appointed to the independent command of the British troops in Italy. On Dec. 4 the line allotted was taken over. The troops composing the force were: XIV. Corps (Lord Cavan); 5th, 7th, 23rd, 41st and 48th Divisions. Later, when it was decided not to maintain as large a force in Italy as was originally intended, Gen. Plumer returned to France and was succeeded in command on March 10 1918 by Gen. the Earl of Cavan. Lt.-Gen. Sir J. M. Babington assumed command of the XIV. Corps. The 41st Div. returned to France in March, followed by the 5th Div. in April. In Oct. the X. Italian Army—including the XIV. British Corps (less 48th Div.), and the XI. Italian Corps, later temporarily reënforced by the XVIII. Italian Corps—was placed under the orders of Lord Cavan for what proved to be the final offensive. The 48th Div. was temporarily attached to the XII. Italian Corps.

Egypt.—In Jan. 1915 the garrison of Egypt had been enlarged by the arrival of troops from England, India, Australia, and New Zealand to a total strength of 68,000. They were at that time organized as: Army Troops; Indian Expeditionary Force—consisting of the 10th and 11th Indian Divs. composed of British and Indian units; East Lancashire (Territorial) Div.; Australian and New Zealand Army Corps (Lt.-Gen. Sir W. Birdwood), comprising the 1st Australian and the New Zealand and Australian Divs. The garrison at the outbreak of war was commanded by Maj.-Gen. the Hon. J. H. Byng, who was relieved in the increased command at the end of Sept. 1914 by Lt.-Gen. Sir J. G. Maxwell. In March 1915 the expedition to the Gallipoli peninsula was launched from Egypt (which acted as lines of communication to the force), and the remainder of the troops were organized for the defence of the Suez Canal. Lt.-Gen. Sir A. J. Murray was appointed to the command in Jan. 1916 with Maj.-Gen. A. Lynden Bell as chief of the general staff, Maj.-Gen. W. Campbell as senior administrative staff officer, and Maj.-Gen. E. A. Altham as inspector-general of communications for the whole Mediterranean. Lt.-Gen. Sir J. G. Maxwell retained the position of High Commissioner.

The forces, reënforced by the withdrawal of the Dardanelles Expeditionary Force and from France, were organized for the defence of the Suez Canal, with the XV. Corps (Horne) at Port Said, the IX. Corps (Byng) at Suez, the Anzac Corps (Godley) at Ismailia, and the VIII. Corps (Davies) in reserve. The 2nd and 4th Australian Divs. were in process of formation. The 46th Div. arrived from France but returned before being incorporated in a corps. After the abortive Turkish attack the following reductions and changes took place gradually.

In 1916 the VIII., XV. and IX. Corps H.Q. returned to France, where they were reconstituted, the 42nd Div. (Feb.), 31st, 1st and 2nd Australian (March), New Zealand (April), 2nd and 4th Australian (June) and 11th (July) Divs., proceeding to France in the months shown, and the 13th Div. to Mesopotamia in March.

In June 1917, after the first battle of Gaza, Gen. Sir E. H. H. Allenby replaced Lt-Gen. Sir A. Murray in the chief command, and in July the Eastern Force was under Lt.-Gen. Sir P. W. Chet-

wode, and the desert column under Maj.-Gen. Sir H. G. Chauvel. In the early part of 1918 further reorganization became necessary, and in Aug. 1918, prior to the final offensive, the forces were organized as: G.H.Q. troops; Desert Mounted Corps (Lt.-Gen. Sir H. G. Chauvel), 4th and 5th Cav. Divs., Australian and New Zealand Mounted Div., Australian Mounted Div.; XX. Army Corps (Lt.-Gen. Sir P. W. Chetwode), 10th, 53rd, 60th Divs.; XXI. Army Corps (Lt.-Gen. Sir E. S. Bulfin), 3rd (Lahore), 7th (Meerut), 54th and 75th Divs.; Palestine lines of communications; forces in Egypt—force troops (including Sollum District), Alexandria District.

Salonika.—The Allied forces, in anticipation of the Greek nation joining the Entente Powers, commenced to assemble in this theatre of war in Oct. 1915, under the command of Gen. Sarrail of the French army. In this first phase of operations (the attempted relief of Serbia, and the withdrawal to and the defence of the Salonika region), the British forces engaged were under the command of Lt.-Gen. Sir B. T. Mahon, and included the 10th, 22nd, 27th and 28th Divs. The 27th Div. was transferred to Egypt at the end of Oct. but returned to Salonika in Nov. 1915. These were followed by the 26th Div. from France in Jan. 1916. In April 1916 the British forces were organized as: Army Troops (including Royal Flying Corps and a mounted brigade); XII. Corps (Lt.-Gen. Sir H. F. M. Wilson), 22nd, 26th and 28th Divs.; XVI. Corps (Lt.-Gen. Sir G. Milne), 10th and 27th Divs.; garrisons of the Islands of Mudros, Imbros, Tenedos and Thasos. Gen. Sir G. Milne assumed command of the British forces in May 1916, and Lt.-Gen. Sir C. J. Briggs took command of the XVI. Corps. The 60th Div. was transferred to Salonika from France in Jan. 1917 for the spring offensive of that year, but proceeded to Egypt in June of the same year. In Aug. 1917 the force was further reduced by the withdrawal of the 10th Div. to Egypt. Other transfers and changes of organization did not affect the major formations; but the strength of the divisions remaining was of course diminished when the brigades, as in other theatres, were reduced from 4 to 3 battalions in the spring of 1918.

These 4 divisions later formed the "Army of the Black Sea." They were gradually diminished by the course of demobilization, and as the result of events and decisions on Middle Eastern policy. During 1918 and 1919 various British forces operated in the Caucasus, Persia and Transcaucasia, and a military mission accompanied Gen. Denikin's (afterwards Gen. Wrangel's) operations in South Russia in 1919–20.

Mesopotamia.—Early in Feb. 1915 an Indian Expeditionary Force (known as "Force D") was dispatched from India under the command of Lt.-Gen. Sir A. A. Barrett (who was shortly succeeded by Gen. Sir J. E. Nixon). This force seized Basra as a base and advanced on Bagdad. The total strength of the force at this period was 6,717 British and 19,245 Indian combatants, 5,895 non-combatants and 11,000 animals, including camels and mules. In Jan. 1916 Lt.-Gen. Sir P. H. N. Lake succeeded to the command, and the 3rd Lahore and 7th Meerut Divs. were transferred from France. Then followed the battle of Ctesiphon, the retreat to Kut and the surrender there of the 6th Poona Div. in April 1916. The force (6th Cav. Bde., 3rd, 7th and later 13th Indian Divs.) organized to relieve Kut was commanded by Lt.-Gen. Sir F. J. Aylmer, who was shortly succeeded by Lt.-Gen. Sir. G. F. Gorringe. On Aug. 28 1916 Lt.-Gen. Sir Stanley Maude was appointed commander-in-chief of the force. It was now organized as: base and lines of communication; Bushire detachment; Euphrates line—15th Indian Div.; Tigris Corps (Lt.-Gen. A. S. Cobbe), comprising 6th Indian Cav. Bde., 3rd Lahore and 7th Meerut Divs., 13th and 14th Indian Divs. Shortly afterwards the Tigris Corps was reorganized as the I. Indian Corps (Cobbe), comprising 6th Indian Cav. Bde., 3rd Lahore and 7th Meerut Divs.; and the III. Indian Corps (Lt.-Gen. Sir W. R. Marshall), comprising the 13th and 14th Indian Divs. On Nov. 18 1917 Lt.-Gen. W. R. Marshall was appointed commander-in-chief owing to the death of Sir Stanley Maude. The 3rd Lahore and 7th Meerut Divs. were transferred to Egypt in April and Jan. 1918 respectively. Various reënforcements had been added to the force from time to time. By Nov. 1918 there were present an Indian cavalry div. (6th, 7th, 11th, and later 3rd Indian Cav. Bdes.); I. Indian Army Corps (Cobbe), 17th and 18th Indian Divs.; III. Indian Army Corps (Sir R. G. Egerton), 13th and 14th Indian Divs.; 15th Indian Div.; North Persian Force (Maj.-Gen. L. C. Dunsterville), 36th and 39th Indian Inf. Bdes.

North-West Frontier of India.—From 1914 to 1917 frequent risings took place on the N.W. frontier, followed by punitive expeditions which in many cases were of considerable strength (one or two mixed brigades and sometimes more). Three divisions were maintained as war strength on the frontier throughout the period of the World War, and these divisional headquarters acted as controlling headquarters or groups of columns formed substantially by their respective divisions, though the order of battle was modified as required. The 1918 operations in Persia and in the Caspian region were carried out very largely by forces working under the orders of the 4th Quetta Div. of the Indian Army.

North [illegible]—Operations in this theatre took the form, initially, of occu[illegible] and various points along the Murman railway and [illegible]ons in the spring and summer of 1918, in order to prevent the Germans and the Finns from doing so. The Allied forces were small, and were to form a nucleus for an army to be created from Russian and Czechoslovak sources. In Aug. 1918 operations extended to Archangel and to the Archangel-Vologda railway by another force. This too, though larger than that on the Murman line (numbering some 14,000 organized troops), was meant chiefly as a nucleus upon which a Russian army could be built up for operations against the Soviet Government. In May 1919 two reënforcing brigades, specially formed, were sent to Archangel, and somewhat later a small additional force was dispatched. In the spring of 1919 it had been decided to evacuate both North Russian theatres of operations, and Gen. Lord Rawlinson was sent as commander-in-chief to coördinate the two operations of withdrawal. The evacuation was successfully completed on Sept. 27 for Archangel and on Oct. 12 for Murmansk.

Other Theatres.—It is unnecessary here to deal in detail with the organization of the British forces in other theatres of war. Under DARDANELLES, EAST AFRICA, and similar headings, the facts are given elsewhere. Some idea of the variety and complexity of the tasks which British and British Dominion military organization had to cope with in the years 1914–20 is afforded by the fact that the subsidiary theatres included Cameroon, Togoland, German South-West Africa, Tsingtau (China), South Russia, the Caucasus, North and South Persia, Aden, the Gulf of Oman, Baluchistan, Burma, Samoa, and New Guinea.

Statistics.—In Aug. 1914 the total strength of the British army, in all theatres of action, was as follows: regular army, officers 10,800, other ranks 236,632; army reserve, 145,347; special reserve, officers 2,557, other ranks 61,376; Channel Isles and militia, officers 176, other ranks 5,437; territorial force, officers 10,684, other ranks 258,093; territorial force reserve, officers 661, other ranks 1,421; Bermuda and Isle of Man volunteers, officers 18, other ranks 312—a total of 24,896 officers and 708,618 other ranks.

In Nov. 1918 the army figures showed a grand total of 193,102 officers and 4,755,242 other ranks (excluding 388,599 Indian troops). The expeditionary forces alone comprised 112,200 officers and 3,114,679 other ranks; among the officers were 93,608 British, 13,382 Colonial, 4,991 Indian native, and 217 Egyptian; and among the other ranks were 1,981,667 British, 291,018 Colonial, and 254,457 Indian native. In the United Kingdom there were 61,694 British officers, 1,321,617 British troops of other ranks, 9,720 Colonial officers and 210,353 Colonial troops of other ranks. The remainder were in India and foreign garrisons and dependent ports.

The total casualties reported up to March 14 1920 comprised: killed (including died from wounds and other causes, but not including 101,000 among the "missing" now "presumed dead"), 42,348 officers and 724,500 other ranks; wounded, 97,908 officers and 1,993,081 other ranks; and "missing," 4,211 officers and 242,772 other ranks (of these 101,000 had been "presumed dead" on lapse of time, but are not included in the figure for "killed"). (B. B.-H.)

Demobilization.—Practically the whole man-power of the nation had been mobilized during the years of the World War. Demobilization was not therefore an exclusively military problem. It was as much an economic and industrial one; and the reëstablishment of particular industries on a peace footing would depend on the order of priority of release observed. It is, indeed, impossible, in formulating a modern scheme of demobilization, to reconcile entirely the antipathetic claims of the individual and of the State; and the War Office Army Demobilization Committee—which was representative of civil as well as military interests—decided, after considering all phases of the problem, that in the national interest a soldier's entitlement to priority of release must depend on his civil occupation rather than on the nature and length of his service with the Colours (*see* DEMOBILIZATION AND RESETTLEMENT). The Committee went further. They decided that two particular classes of men—called "Demobilizers" and "Pivotal Men" respectively—must be released in advance even of the period of general demobilization. To the early release of "Demobilizers"—that is, the men actually required in putting through the demobilization process—no objection was, or could be, raised; but the release of "Pivotal Men"—that is, men either of special technical or administrative capacity or belonging to "key" indus-

tries, as agriculturalists and miners—met with much opposition. Many of the men of this class, of course, had been the subject of appeal after appeal to tribunals for exemption and had little military service to their credit. Why, then, it was contended, should they be released before men who had served four and five years in the army? Pivotalism indeed was called "favouritism." But it should be remembered that the maximum number of "Pivotal Men" to be released was fixed at not more than 150,000 (a figure which included the "Demobilizers" as well) and that they were granted priority solely for the purpose of assisting in the reorganization of the various industries and thereby of increasing the capacity to provide employment for the less highly qualified men. On the other hand, it is true that some men of 19 and 20 years of age, with little or no technical experience, were certified as "Pivotal" by the Ministry of Labour and given early release, while some bona fide "Pivotal Men" were not released until long after the general demobilization period had begun.

As early as January 1915 the question of demobilization had been given consideration. It was not, however, until February 1917 that a draft scheme was drawn up. This scheme, applicable to troops serving in France only, was a mere outline, but formed the basis of the detailed "Regulations" finally adopted. It provided that men should be withdrawn individually from units (in an order of priority previously determined but depending in the main on individual industrial qualification) and formed into special parties called "Dispersal Drafts." These drafts would be sent to appropriate "Dispersal Stations" in the United Kingdom and there demobilized; each draft for a particular "Dispersal Station" being, so far as possible, composed of men whose homes were in the "Dispersal Area" (the United Kingdom being, for demobilization purposes, divided into 18 special areas called "Dispersal Areas") in which the "Dispersal Station" was situated. When, by this process of individual withdrawal of personnel, a unit had been reduced to a "cadre" strength—such strength depending upon the number of men that would be required to bring home the unit's vehicles, animals and regimental equipment—it would be brought to the United Kingdom and disbanded or re-formed, as the case might be, and the remaining demobilizable personnel sent for dispersal.

The scheme did not receive War Cabinet approval until November 1917, but Cabinet sanction was taken for granted; and in March 1917 an Army Order was issued providing that the "Industrial Group" of each soldier, his particular trade or calling, and whether he was married or single, should be recorded either in his Army Book 64 (if he was serving in a theatre of war) or his Army Form B103 (if he was serving at home or in an overseas garrison). The purpose of this Order, of course, was to provide an authentic record of each soldier's pre-war occupation, which would serve as a basis in applying the industrial priority principle. But the priority which, in the national interest, ought to be granted, on demobilization, to men of particular industries and professions had also to be determined. This was a matter for the Ministry of Labour, not the War Office; and a departmental "Demobilization Priority Committee" was therefore convened for the purpose of drawing up an industrial priority schedule. A further committee was set up, for the purpose not only of securing executive coördination but of determining, during the demobilization period, such revised instructions on priority as might be deemed necessary on public grounds or from the state of employment in particular industries.

In December 1918 Parts I. and II. of Army Demobilization Regulations were issued and circulated under cover of Army Order 7 of 1919. These Regulations set forth every detail of the dispersal procedure. Of the actual executive machinery set up in connection with the scheme it may be said that it worked throughout with unfailing smoothness and precision, in spite of arbitrary and unexpected fluctuations in the rate of dispersal. One detail of procedure must also be specially noted. In the original scheme—of which the basic principle was priority according to individual industrial qualification—it was provided that ten per cent of each dispersal draft should consist of men who, irrespective of their civil qualifications, had served longest in the theatre of war or overseas command concerned. After the Armistice, however, the demand for a speeding-up of the rate of dispersal became so insistent that the strict order of the Regulations could not be adhered to. The hands of the military authorities were forced and many new classes of men were made eligible for early release. The result was that the promised ten per cent of long service men could not always be included in dispersal drafts; and the Field Marshal Commanding-in-Chief in France wrote pointing this fact out and insisting that, as the original scheme had been explained to the men, it might seriously affect their discipline if it were departed from.

After the Armistice, of course, demobilization became a matter of immediate public concern, and as a General Election was pending the demand for more speedy release acquired a political significance. The initial slowness in the rate of dispersal was, to a great extent, inevitable, and was due to shortage of transport and to finely strung lines of communication in the theatres of war; but it must also be remembered that the War Cabinet order to accelerate the speed at which demobilization was proceeding was not given until December 8 1918. Certain influential critics however preferred to attribute the early delays to a malignant unwillingness of the army authorities to let the men go; and considerable unrest was aroused not only amongst the public but amongst the troops themselves. Many letters were, in fact, received in the War Office from individual soldiers complaining that their commanding officers were deliberately refraining from taking steps to effect their demobilization.

The agitation continued and the situation was verging on the critical. Difficulties with the soldiers occurred at Folkestone and elsewhere. Something had to be done to stem the flood of discontent. On January 29 1919 an Army Order was issued abolishing the principle of industrial priority and substituting that of release on grounds of age or length of service. The good effect of this order was instantaneous. Yet the new Army Order wrought no fundamental change. The principle of release by age and length of service had always been recognized and had been embodied in the original scheme. The machinery of dispersal was in no way altered; the transport problem was not solved; in short, the maximum rate at which dispersal could be carried out remained as before. Just so many men as were released under the new Army Order could have been released under the old rules. And that the demand for release was as acute as ever was proved by the statistics of letters received at the War Office. After the issue of the Army Order the weekly numbers of letters received asking for the release of particular soldiers increased rapidly—in one branch only, from 4,821 for the week ending Jan. 25 1919 to 17,506 for the week ending May 10 1919. In view of these facts, it would appear difficult to explain the sudden soothing effect of the Army Order. But indeed the reason is not far to seek. The Order was accompanied by a Royal Warrant (Army Order 54 of 1919) increasing the rates of pay of men in the army, and the increases were on a generous scale. The mere changing of the principle underlying the releases would have been ineffectual—was, indeed, unnecessary. What was needed was some unmistakable proof that the military authorities were not acting in any arbitrary or obstructive manner. The idea had got abroad that men were being deliberately retained; and the issue of the warrant, coupled with the frank statement (accompanying Army Order 55) by the Secretary of State for War, threw a very different light upon the whole matter.

The total number of men (inclusive of Royal Air Force personnel) demobilized from November 11 1918 to September 29 1920—the date for which the last official Bulletin was issued—was 196,920 officers and 3,866,668 other ranks. (E. S. H.*)

II.—The French Army

Although the decree of Aug. 23 1793 brought into being the principle of the nation in arms, it was not until after the war of 1870–1 that the principle of personal service for all was established in practice (law of July 27 1872). Thenceforth no one could take the place of another. Inequalities in peace-time service, however, still existed, through the operation of the ballot and certain concessions allowed to men on account of family circumstances, or educational qualifications. In 1889 a second stage was reached. Military service in peace-time was reduced to three years, but many categories of citizens, *e.g.* students and supporters of families, would serve only six months. In the event of war every citizen between the ages of 20 and 45 would be called, as all having served would be able to participate in the first engagements.

By the law of March 21 1905, the inequalities in the duration of military service in peace-time disappeared. Henceforth in France military service was declared personal and equal for all in peace-time as in war. Service in peace-time, however, was reduced to two years. The reduction of the duration of service to two years, together with the decrease of the French birth-rate, placed the French army in peace-time in conspicuous inferiority by comparison with the German army on a peace footing; and in 1910 an increasing volume of opinion demanded a return to three years' service.

In 1913 the German danger was apparent to the great majority of the French people. After bitter and prolonged discussions,

personal and equal service for everybody for three years in times of peace was adopted (law of Aug. 7 1913). Thanks to this law, France, with a pop. of about 40 millions (39,601,599), was able to raise an effective force of 3,780,000 men in a period of 15 days (Aug. 1 to 15 1914) by the calling up of 2,887,000.

In 1914, the French army on a peace footing was increased to 823,251 men of whom 777,215 were metropolitan troops and 46,036 colonial. The metropolitan troops were thus classified:—775,681 *hommes de troupes* (of whom 43,486 were in Morocco), viz. 47,251 *sous-officiers*, 48,357 corporals, and 680,073 privates, and in addition 1,534 administrative employés. The colonial troops comprised 45,932 *hommes de troupes* (of whom 20,420 were in Morocco), viz. 4,756 *sous-officiers*, 3,690 corporals and 37,506 privates. Eighty-four non-commissioned officers were employed at the headquarters of the colonial army. The term *hommes de troupes* corresponds in France to that of "other ranks" in Great Britain, viz. all ranks exclusive of commissioned officers. The exclusion of officers accounts for the difference between 2,887,000+823,251 and the total of 3,780,000 shown as the strength on mobilization.

From Aug. 16 1914 to June 30 1915, a further 2,700,000 men were called up to the army. From the class 1889 to the class 1916 all men were called to the colours; this amounted to a recall of 6,444,000 men. The three years' law and the previous military laws had thus given France (1) a covering army which made her front inviolable, or at least which determined the Germans to seek to envelop a wing rather than attempt to break the front; (2) a peace army able either to absorb or to provide cadres for a considerable number of reservists and of men of the territorial army. The rapid influx of so great a number of men caused high hopes in France of a happy and rapid solution of the war, when it started in 1914. But as things turned out its only result was to enable her to await, without disaster, the coming into line of Italy on the one hand, and the formation of a great English army on the other.

In Aug. 1915, when the war had already lasted one year, it was realized in France that Lord Kitchener was right in anticipating a war of several years. He himself had undertaken to form a military organization for a duration of three years; and France, having already called up numerous classes of reservists and of young soldiers, now became less hasty in calling to the colours those who remained. Thus from Aug. 1 1914 to June 30 1915 there were mobilized 5,587,000 men, which brought the total up to 6,444,000 men; from July 1915 to Oct. 1 1915 there were mobilized only 1,440,000 men in small batches.

The enrolments made by France in the course of the war reached a total of 7,842,000 French and 475,000 N. African and colonial troops, making a grand total of 8,317,000 men.

In the course of the war losses—in killed, wounded, prisoners, deaths from sickness and sick—made the numbers vary of men mobilized in the army and outside it. The need of food supplies also made it necessary to send back a certain number of individuals and parties of agriculturists who were recalled to service from time to time and then again released to work on the land.

At the beginning of July 1915 there began the process of withdrawing from the front men capable of working in munition factories. Such men were no longer, strictly speaking, mobilized, but they remained "mobilizable," and were recalled to the front when there was no longer any fear of a shortage of munitions, or when the need of the front line became dominant, as when Clemenceau at the beginning of 1918 withdrew the young workers from the factories. The following table shows by categories variations of strength.

	Mobilized strength.	Men liable to mobilization employed in the interior.	Agricultural gangs, and agriculturists on leave.
Aug. 15 1914	3,781,000	465,000	..
July 1 1915	4,978,000	122,000	50,000
" 1 1916	4,677,000	595,000	70,000
" 1 1917	4,512,000	1,183,000	100,000
" 1 1918	4,340,000	1,374,000	45,000
Nov. 1 1918	4,143,000	1,387,000	25,000

On Aug. 15 1914 the French army at the front had reached the strength that Joffre used in the battles of the Ardennes, the Marne, and the "Race to the Sea." July 1 1915 stands for the period at which it was hoped to pierce the front in Champagne. More men were made available for the armies, and also for the work preparatory to the offensive (which was to take place in September); no heed was paid to the needs of the country, since it was hoped the war would very soon end.

The 465,000 men who had been allowed to return to the interior in Aug. 1914, for public services, for the guarding of lines of communication, and for administration, were recalled to the army in July 1915. Although there remained in the interior 122,000 men (besides 30,000 agricultural workers), these 122,000 were mobilized men in the factories, and the need for munitions and for artillery was very great. From the beginning of July 1916 the English army brought a great aid and relief to France, where exhaustion was beginning to make itself felt. The mobilized strength was beginning to fall away; it was not possible to replace the dead by calling up fresh men. Moreover, it became obvious that the conditions of the war needed munitions on an ever-increasing scale, and so the munition factories were crammed with workers.

The definitive losses sustained by the French army in the World War reached a total of 1,317,000 French and 66,000 native troops, making in all 1,383,000 dead. As shown by the following table the losses in killed were very heavy in 1914 and in 1915, heavy in 1916, relatively light in 1917, and heavy again in 1918.

	Killed, or died of wounds.	Average per month.	Percentage of monthly losses in comparison with strength.
1914	301,350	60,270	2·95%
1915	348,850	29,070	1·09%
1916	252,300	21,020	0·71%
1917	163,700	13,640	0·46%
1918	250,800	22,100	0·77%

In 1914 a Frenchman belonging to the army had two chances of life and one of being killed; he had hardly any chance of remaining without a wound. In 1915, this man had six chances of living to one of being killed, while the chances of being or not being wounded were nearly equal (two to one and a half). It was during the year 1917 that the dangers were the least; on an average one had six times as great a chance as in 1914 of not being killed.

If one takes into account the combatants in each of the arms of which the French army was composed, one sees diminishing little by little, but in a very perceptible manner, the number of infantry and cavalry, while the strength of the engineers maintained itself without great change. But the combatant strength of the artillery and air service was augmented in number by two to one in the case of the artillery and by six to one in that of the air service.

Combatant Strength

Arm.	May 1 1915.	July 1 1916.	Oct. 1 1917.	Oct 1 1918.
Infantry	1,525,000	1,447,000	1,142,000	850,000
Cavalry	102,000	93,500	71,000	63,[illegible]
Artillery	395,000	495,000	522,000	601,000
Engineers	104,000	125,000	121,000	117,000
Air Service	8,000	24,000	35,000	52,000

The army evolved towards material power, the rifle lost ground to the machine-gun, but the machine-guns more and more took second place to the artillery. As for the air service, it grew to an extraordinary extent. If, taking a table of numbers, a mathematician were to establish a rising curve, he would come promptly to the conclusion that in a limited number of years there would be more men fighting in the air than on the ground. And if in fact, despite the mounting numbers of the artillery and of the air service, the infantry remained queen of battles, the queen's retinue was no longer one of men on horse-

back, but one of great masses of cannon and machine-guns moving by her side and over her head.

So far we have dealt with the strength: the examination of the losses is still more conclusive.

Losses

Arm.	1914.	1915.	1916.	1917.	1918.
Infantry . . .	283,320	323,160	221,920	134,710	182,120
Cavalry . . .	3,790	3,620	2,830	3,180	7,690
Artillery . . .	8,560	11,100	16,800	15,500	27,725
Engineers . .	2,880	6,960	5,475	4,415	7,155
Air Service . .	32	260	620	820	1,965

The variations in the losses of the cavalry are practically without meaning, for the cavalry fought sometimes as infantry in the trenches, sometimes on foot, at other times on horse. Still it should be noted that in 1914 as in 1918, when the cavalry had occasion to engage in open warfare, *i.e.* to work as mounted men, their losses were considerably increased. During the pursuit-battles of 1918 the losses were particularly heavy.

Whilst the strength of the artillery increased from May 1915 to Oct. 1918 in the ratio of four to six, the proportion of the losses rose in ratio eleven to twenty-seven. For the air service the strength increased in the ratio of 8 to 52, that is to say 1 to 6·5—the losses increased in the proportion of 260 to 1,965, *i.e.* 1 to 8. The queen of battles, magnificently escorted in 1918 by the gun and the aeroplane, suffered less than before; it was she, however, who still ran relatively the greatest danger. She remained queen. It is of interest also to notice that the war of movement was more murderous than trench warfare. The year 1916 was for the French army the year of Verdun and the Somme, fantastic battles when artillery projectiles fell like rain in a storm. However, this battle of a year cost far less than the six months' battle in 1914, although the strengths engaged were practically the same. In 1918 the infantry lost 182,000 men out of a strength of 850,000 men; in 1916 the proportion was 220,000 out of a strength of 1,450,000. Strong souls were and always will be needed to lead men in the battle of open warfare; and the education of an army must be directed accordingly.

Man-Power.—The evolution of the French army from 1910 to 1914 would not be sufficiently indicated, nor would one understand the defeats from Aug. 18–24 1914, followed by the victories of Sept. 5–12, if one were only to study a table of strengths. How could it happen, one might say, that Gen. Joffre, to whom by Aug. 15 1914 France had entrusted 3,780,000 men—not to mention the precious aid and increment of strength brought by the British and the Belgians—was beaten in the battles of the Frontiers? On the Sambre, the French army, swelled by reserve divisions attached to it, had during Aug. 22–23 a numerical equality with the troops of the German II. Army to whom they were opposed. In the Woevre the III. French Army, augmented by the reserve divisions attached to it, was equivalent in strength to the opposing V. German Army. In many places in the great battle that took place from Mülhausen to Maubeuge, German units triumphed easily over French units of the same strength. At the Marne the contrary happened.

To find the explanation of this curious paradox, it is sufficient to follow the evolution of the French army before the war, and to compare the age of the combatants who were fighting respectively in the two camps. To obtain the numbers sent to her armies France had to incorporate all the recruit classes from class 1889 (men born in 1869) to the 1916 class. The men of the classes 1889–1905 had done three years' service, or in certain cases six months only. Recalled twice for a period of 28 days, and once for a period of 13 days, the men who had remained with the colours for a short time were not in Aug. 1914 sufficiently trained to be battle-worthy. That is why the army given to Gen. d'Amade for ensuring the defence of France between the Oise and the sea was valueless. Field-Marshal French obviously could not count on it for ensuring the protection of his left flank. It was necessary to have several months of war to give any fighting value to the units of the territorial army.[1] The men belonging to the classes 1905–13 had uniformly served two years with the colours, and would have been able without difficulty to bear their share in battle if they had had proper cadres. But even though two years' training suffices to make an excellent soldier, one cannot in that time turn out good non-commissioned officers with the aptitude to command sufficiently well established to be recovered quickly after several years spent in civil life. As the army in times of peace had not enough cadres of N.C.O.'s and of subalterns to give sufficient for the formation of reserves, these reserve formations had to acquire cohesion before being in a state fit for fighting. To command these territorial and reserve units it was necessary to draw officers from civil life or older officers from the active army. In the reserve divisions, indeed, it had been possible to place a certain number of officers of the active army. But no steps had been taken to provide any for the territorial army. The profession of a soldier, like any other, requires an apprenticeship; but officers of the reserve or territorial army in times of peace might have resigned if compelled to attend frequent trainings; and so there was nothing for it but for them to serve their apprenticeship in war—a matter of many weeks. As for the older officers of the active army, retired under the age limit, they were not sufficiently young to pass on their energy to the others. The reserve divisions in Aug. 1914, therefore, were not in a condition to be considered as combatant, for lack of good cadres and also lack of youth.

The three years' law was expected to furnish the cadres which the two years' law had failed to give; but having been voted only the year previous to the war, it was not able to produce the effect which was hoped from this point of view. The three years' law called up the 1913 class in advance. Prior to this law the men of a class were called to the colours in the month of Oct. of the following year. Thus, under the régime of the two years' law, men born in 1893, being 20 years old in 1913, were called the 1913 class. Had they been summoned on Oct. 1 1914 they would not have taken part in the battles of the Frontiers or those of the Marne. When the three years' law came into force these young men joined the colours in the month of Oct. 1913, and in consequence, at the moment of the commencement of the campaign, they had between nine and ten months' service, and they did splendidly in the battles of the Frontiers and the Marne. It will be noted that these young men were 20 years old at enrolment, instead of 21 as under the previous laws. Fears, therefore, had been entertained that enrolment at so early an age would adversely affect them. For this reason the calling-up was postponed in the case of any conscript whose physical condition left anything to be desired. The 1913 class did not provide, therefore, at the moment of enrolment, more than 170,000 men instead of 210,000, which was the usual figure. Nevertheless, the three years' law was welcome at the moment, since it gave both the mobilized army and, in particular, the peace-time army an addition of strength equivalent to four army corps. From this aspect the vote of the three years' law was the capital point of the French army's evolution from 1910 to 1914.

The Germans, thanks to the greater size of their population and to their higher birth-rate, were able to increase each year their strength in peace-time; and, because in Germany the uniform was popular, the candidates for officers and non-commissioned rank of the active army and of the reserve were superabundant.

In these conditions it was feared in France that the weak units of the protective forces in the frontier regions might be suddenly overwhelmed, and the concentration of the armies behind them thereby made impossible. To build up in peace-time the strength of the units forming part of the *couverture*, and to increase the number of units assigned to it, was the principal aim of the three years' law. Commencing in the month of Oct. 1913, the corps of the Covering Force were filled up with the numerous contingents of young soldiers of the 1912 and 1913 classes; this increase was so considerable that the peace strength became almost that of a war footing. The period of Oct. 1913 to May 1914 was extremely critical, owing partly to the overcrowding in the old barracks or in those being constructed and partly to the want of instructional facilities for the increased number of recruits. If the war had broken out during the transitional phase, difficulties without number would have had to be overcome. Fortunately, this did not happen.

At the same time that the three years' law increased the strength in men, it increased also the number of horses in the cavalry and artillery. In consequence of this, the units of the Covering Force found themselves able to take the field almost with their peace-time organization. The difference between peace and war strengths was about four to five. This allowed the reservist element to be easily absorbed in the active element. At no point in the immense field of battle of Aug. 1914 did any weakness manifest itself amongst the troops of the Covering Force; on the contrary, the II. Corps, XX. Corps, and Hache's Div. of the VI. Corps displayed prodigies of valour and saved some situations which were extremely delicate.

The formations of the Covering Force were favoured with regard to cadres, in comparison with other units of the interior. Since they were liable to be attacked immediately after, and perhaps without, a declaration of war, it was desirable in the meanwhile to maintain them almost on a war footing not only with men but with cadres. But, without denying the value of the advantage of possessing cadres almost at war strength which the Covering Force enjoyed at the expense of the army of the interior, it must be recognized that the preponderant influence is the *age* of the troops. The corps of the Covering Force were younger than the corps of the interior, the latter were younger than the reserve divisions, and the divisions of the reserve had not the age of the territorial army. This is not the place to argue that age freezes the courage—that question lies in the domain of psychology and must be left to research in that branch of study. It may be affirmed, however, that the process of acclimatisa-

[1] In France the "territorial army" is formed on mobilization from reservists (officers and men) of the older classes.

tion necessary in turning from the habits of peace to the trials of war is harder in proportion as youth has passed and the instruction acquired during the years of service with the colours has been effaced by time. If this applies to the French it is equally true of the Germans. In the early days of the war, when of equal ages, the French and Germans found themselves on an equal footing; but where the Germans were younger they won.

Now, in any case, the French population consisting of 40 million souls, and the German of 70 million, in one mobilization class Germany had seven soldiers to France's four. But, further, it was especially in the 30 years prior to the war that the difference in the birth-rates made itself felt. One can say then without appreciable error that the last classes called to the colours gave eight to Germany and only four to France.

The army corps of the French Covering Force, in which 80% of the personnel consisted of the three youngest classes, had a mean age of 22–22½ years. The army corps of the interior, composed half of men of the younger classes and half of reservists, had a mean age of 25–26 years. The reserve divisions had a mean age of 31–32 years. The army corps of the German active army had a mean age of no more than 22 years in the Covering Force, and 23–24 years in the interior, while the German reserve army corps had one of not more than 25–26 years. In brief, all the army corps of the Germans, whether active or of the reserve, were still under the influence of the lessons acquired during their active military service, while the French reserve divisions had everything to relearn.

Therefore, if one is to compare the strengths present in the Frontier battles, one must not count the divisions of French reserve any more than the reserve brigades which followed the active army corps, or only count them as of very small value. For battle purposes the numerical superiority must be considered in the first encounters to have been in favour of the Germans. But the reserve divisions quickly recovered themselves; their acclimatization was rapid. Already at the battle of the Meuse there was notable progress; at the Marne, where they were led vigorously, they called forth the respect of the enemy.

In 1914 France was organized to place under arms the whole population capable of carrying arms. It has already been remarked that the stages of evolution towards the ideal of 1793 were slow. Even after Sedan, Gambetta was able only to call up men by categories—first the unmarried, then married men without children. Only in 1905 did service become obligatory, personal and equal, and it was not until 1913 that the law was reached which saved France by giving, with equality, a strong peace army which could absorb the number of reservists and cover the mobilization and concentration. It is important to note the fact that while on Aug. 22 1914—that is to say, three weeks after the order of mobilization—the army corps of the Covering Force were complete, the army corps of the interior were only just ready, the divisions of the reserve were not up to the mark, and the units of the territorial army were still valueless. This respite of three weeks which the French army enjoyed arose from two causes: the resistance at Liége and the extension which the Germans gave to their enveloping manoeuvre. It may fairly be asserted that it was the reënforcement of the French Covering Force, much more than the value of the French fortresses, which caused the German staff to seek to gain the valley of the Oise by the right of the army before the attack. And the resistance of Liége aggravated the effect of the delay inherent in this place of attack.

The evolution of the French army from 1910 to 1914 in respect of its strength, the reënforcement of the Covering Force and the peace-time order of battle, thus saved France in spite of the absence of a natural frontier which exposed her to the greatest difficulties, if not to actual defeat.

When the war of movement ended and trench warfare commenced, it was bitterly regretted that the factories had been emptied of all their mobilizable workers; the very principles which had governed the evolution of the army towards universal, personal and equal service were blamed. It was deplored that these men had not been left at work in their workshops whilst the others went to fight.

It may be that these reproaches were ill-founded. If the 559,000 men who on July 1 1917 were in factories had remained there in Aug. and Sept. 1914 instead of going to the war, perhaps there would have been munitions in the arsenals, but perhaps also the French army might not have had need of them, because they would have been beaten by the numbers of the enemy.

It is not justifiable, then, to say that the evolution of the army between 1910 and 1914 was on wrong lines. It was because the Germans gave so wide a sweep to their enveloping movement that space and time allowed the French commander-in-chief to place on his left wing the V. Army and a group of reserve divisions, and to get in touch with the English army. This space and time Prussia had meant to refuse to France in 1871 in drawing the new frontier. To gain space and time had been the object of those who had organized the defences of the mutilated frontier; it was the purpose, equally, of the troops of the Covering Force. To lessen the allowance of space and time required for the French army to mobilize and concentrate on the frontier was the constant preoccupation of the staff from 1875 up to the month of Aug. 1914.

The Covering Force.—It is not possible here to deal with the organisation of the fortresses which gave a military frontier to France, deprived, as she was of every natural frontier. We shall limit ourselves to defining the operations which had for their object the creation of a strong Covering Force. These operations determined the order of battle of the French army.

In the first place there was built up one higher formation to which almost exclusively was entrusted the duty of forming a Covering Force to face Germany; the VI. Corps was this great unit. Alone, this army corps watched over the frontier in 1875. Next, Germany having placed in Alsace-Lorraine very large numbers, France, in order to keep the balance, had to augment the number of units of the VI. Corps. This, becoming too cumbersome, was divided into two—the VI. (headquarters Châlons) and the XX. (headquarters Nancy). At the same time the region of the VII. Corps (Besançon) was extended to the N. of Belfort as far as the Upper Moselle. This was the position in 1910, when, since Germany showed herself not only more and more aggressive but also more and more strong, it was decided to give the frontier, by the organization of the Covering Force, the means of gaining, if not space, at least the time necessary to put in position in a prearranged order of battle the great military units mobilized by France. For this purpose it was necessary to have the men whom the three years' law provided. When they were promised, a new order of battle was adopted. A new army corps, the XXI., was created, with the duty of providing the covering force in the region of the Vosges. The II. Corps (Amiens), which was a corps of the army of the interior, had its regional limits completely altered; the district adjoining Belgium (Givet to Thionville) was allotted to it, and one of its divisions increased to three brigades furnished the Covering Force from Briey to Givet.

Each corps of the Covering Force became in a fashion the advanced guard of an army. The XXI. Corps was the advanced guard of the I. Army; the XX. Corps that of the II. Army; the VI. Corps that of the III. Army; and the II. Corps became on Aug. 9 1914 the advanced guard of the IV. Army. The I. Corps acted as an advanced guard to the V. Army, sent towards the Sambre, and on the other flank the VII. Corps, when strongly reënforced, became the army of Gen. Pau, operating towards Mülhausen. Behind this formidable system of the six corps of the Covering Force, the commander-in-chief under Plan 17 could put his armies into position. Immediately prior to the war, Gen. Joffre had improved in detail the measures taken for mobilization and concentration in order to avoid as far as possible any loss of time; he sought to gain even hours, in the hope of saving the corps of the Covering Force from having to give ground, by speeding up the intervening stages between the date of the opening of hostilities and the time at which the armies would be strategically concentrated.

Strength.—The French army in peace-time consisted of 21 army corps and three divisions of colonial troops available for service on the frontiers. Of these 21 army corps, the arrival of the XIX. Corps, stationed in Algeria, in time for the first battles was counted upon, though problematical. In addition there were 10 divisions of cavalry. On mobilization the units of the active army were brought to their war strength by the influx of reservists; there was created on an average one division of reserve for an army corps.

In the Frontier battle, Gen. Joffre had under his command not only the 44 divisions of the active army at home but also three active divisions drawn from N. Africa and the Alps, and 25 reserve divisions—a total of 72 divisions of infantry and in addition 10 divisions of cavalry, giving a total of 2,669,000 men for the armies of the north-east.

By Sept. 1 1914 the French army comprised:—21 army corps, 50 active divisions, 25 reserve divisions, 12 territorial divisions, 10 cavalry divisions, army troops, and line-of-communication troops. Altogether there were 62,145 officers and 2,689,000 men—1,135,000 rifles, 25,000 carbines, 106,200 sabres, 2,158 machine-guns, 4,098 field guns, 389 heavy guns, 192 mountain guns, 200 aeroplanes and 18 balloons.

If in addition to the troops which Gen. Joffre was able to place in the battle of the Frontiers, there are added the Belgian army of 6 infantry divisions and one cavalry division, the 4 British infantry divisions which in the first place Field-Marshal French brought, with one and a half divisions of British cavalry, the conclusion is reached that the loss of this battle was caused, not by disproportionate numbers, but by various other factors, amongst which, as already noted, the initial lack of efficiency of the French reserve divisions must be given a prior place.

The order of battle of the French army comprised five armies, allowing four armies to be placed side by side in the first line, and one army in reserve behind the centre and left centre. Each army had at least one division of cavalry in reserve. On the left near the Belgian frontier there had been assembled a cavalry corps. Reserve divisions were placed in the centre of the battle front, between the II. and III. Armies, to carry out the investment of the fortified region of Metz-Thionville or to bar the enemy from the Meuse heights between Verdun and Toul as required. Other reserve divisions were entrusted, concurrently with certain active forces, with the defence of the region of Ste. Geneviève, in front of Nancy and Frouard. A "group" of reserve divisions was brought to the right rear, and a similar group to the left rear of the long line. Belfort, Epinal, Toul, Verdun, Maubeuge received their war garrisons. Lille was declared an "open town" by the Ministry of War. Lastly,

a group of territorial divisions under the command of Gen. d'Amade in the region W. of the Oise was dignified by the name of an army.

Each army had a number of army corps varying according to the different missions of these corps. Thus, for example, the IV. Army, which under Plan 17 (wherein this army was in reserve) had only 3 army corps, had 6 army corps in the Ardennes battles, with, in addition, 2 reserve divisions. A temporary army was formed for the invasion of Alsace under Gen. Pau; this was broken up when Joffre observed how seriously the left flank of the Allies was compromised. An army, called the Lorraine Army, existed for some days in Woevre; it was broken up before even the neighbouring forces knew of its existence. A sixth army was organized near Amiens; this was the army which, reconstituted at Paris, fought the battle of the Ourcq. A ninth army, which at first was an "army detachment" under the IV. Army, was formed during the retreat and fought gloriously at the Marne. In the course of the war, armies were created, broken up, and created anew as the needs of the case demanded. Thus there was formed at Salonika an Army of the East.

After the loss of the Meuse heights, which followed the loss of St. Mihiel, the commander of the III. Army was for a time brought under the authority of the commander of the I. Army. This was the origin of the creation of "Groups of Armies." These had the advantage of simplifying the task of the commander-in-chief, which had become heavier and heavier; but it was evident during the offensive of April 1917 that this part of the machinery was capable of bringing its movement to a standstill. Opinions formed on this subject seem unanimous in considering the army group a temporary formation intended to achieve coördination of movement when many armies were seeking the same objective while the commander-in-chief had too many other urgent occupations to act himself. In 1915 there were three groups of armies, East, Centre, North. For the offensive of 1917, and again for the spring campaign of 1918, groups of armies designated "reserve" (G.A.R.) were formed. In the final advance of Sept.–Oct. 1918 a group of armies of Flanders was formed of Belgian, French and British troops under King Albert.

An "Army Corps" in principle was composed of two divisions of the active army and corps troops and included especially one brigade of the reserve. But certain army corps in Aug. 1914 had 3 divisions—the VI. Army Corps for example. The II. Corps mobilized 5 brigades, but it lost almost at once the 8th Bde., which was attached to the cavalry corps. In the course of the campaign during the stationary period, an army corps was often no more than a sector where troops collected either for battle or for enjoying a period of comparative rest. The number of divisions was extremely variable, as was also the allotment of artillery in a sector.

An infantry "division" originally consisted of 2 brigades of infantry, a company of engineers and a regiment of artillery. In order to give greater mobility and to decrease the proportion of infantry in comparison to the number of guns, one regiment of infantry was suppressed. The ternary order prevailed not only in the regiment of infantry but also in the battalion. The cavalry division did not undergo any great change during the war, although in 1915 two sections of machine-guns were added. The proportion of engineers was increased while many regiments of cavalry were dismounted or broken up.

A cavalry corps was composed of a variable number of divisions of cavalry. On the left wing of the French army the general-in-chief constituted, from the concentration, a cavalry corps in strength of 3 divisions. During the battle of the Meuse, the commander of the IV. Army created a cavalry corps from 2 divisions which had been at that moment attached to him. In front of the I. and II. Armies a cavalry corps was also created for a brief time. In fact, the cavalry corps did not exist as an organized formation; when two or more divisions of cavalry were placed under the same commander the group thus formed was often called a cavalry corps. A division of cavalry had 3 brigades of cavalry and a group of batteries.

Many were the variations through which the order of battle passed in the course of the war. But it is of special interest to mention what the French army of 1914 had become in 1918 when the war was ended; the numbers can be compared with those shown above.

In 1918 there were at the front:—88,488 officers and 2,846,000 men—450,000 rifles only (about one-third of the number in 1914), 400,000 carbines, 33,500 sabres, 19,149 heavy machine-guns, 46,800 light machine-guns (an arm which had not been employed in 1914), 936 guns of 37 mm. calibre, 1,872 Stokes mortars, 36 motor-mounted 37 mm. guns, 208 motor-mounted machine-guns, 6,618 field guns (75 mm.), 7,100 heavy guns, 260 mountain guns, 2,275 guns of position and trench artillery, 3,379 aeroplanes (which the programme for 1919 increased to 6,000), 77 balloons, and 2,385 (a little later 4,626) tanks. In 1914 the army had 19,000 vehicles; in 1918 there were 88,500.

Under the law of Dec. 23 1912, the French infantry in peace-time comprised 173 regiments, of which 164 had 3 battalions of 4 companies each; 8 "fortress" regiments had 4 battalions, and one regiment stationed in Corsica had a variable number of battalions. There were 31 battalions of *chasseurs-à-pied*, of which 18 (6-company) battalions were on the N.E. frontier and 13 were Alpine battalions (6-company also). Four regiments of Zouaves had a variable number of battalions (4-company). Twelve regiments of native *tirailleurs* were composed like the Zouave regiments, but with a depot company in addition. Further, there were 2 foreign regiments, 5 battalions of African light infantry and a number of Sahara companies. The single regiment of firemen engineers of Paris furnished excellent cadres for the units dispatched to the front when after the Marne a shortage occurred of non-commissioned officers and subaltern officers. In principle each active regiment of infantry formed a reserve regiment of 2 battalions. The territorial army was formed of 145 regiments of varying composition according to the resources of the recruiting district; it included 7 territorial battalions of Chasseurs, and 12 territorial battalions of Zouaves. The infantry was armed with the Lebel rifle, model 1886–93. There was one machine-gun section for each battalion of infantry and Chasseurs. Owing to the slowness with which the French Parliament granted the necessary sums, territorial units were not provided with machine-guns at the outset of the war.

The cavalry was composed of 91 regiments, of which 10 were African troops. Each regiment had 5 squadrons in peace and 4 in war. However, the 6 Spahi regiments continued with 5 squadrons. In principle each army corps had a regiment of cavalry, and each division of infantry had a squadron. The other regiments of cavalry formed 10 divisions of cavalry of 6 regiments each. The term "Heavy Cavalry Division" was sometimes applied to those comprising 4 regiments of dragoons and 2 regiments of cuirassiers; that of "Mixed Division" to those composed of 2 regiments of cuirassiers, 2 regiments of dragoons and 2 of light cavalry; and that of "Light Division" to those of 4 regiments of dragoons and 2 of light cavalry. The cavalry was armed with the sabre, carbine, and, in certain regiments of dragoons, with the lance. Each division of cavalry was allotted a group of horse artillery and a cyclist company.

The artillery comprised 62 regiments of field artillery, in 3 or 4 groups of 3 four-gun batteries and 5 autonomous groups in Algeria and Tunis. There were 635 field batteries, 24 batteries of mobile medium howitzers, 35 batteries of heavy artillery, 22 batteries of mountain guns, 30 batteries of horse artillery, 75 batteries of foot artillery—altogether 820 batteries.

The engineers were composed of 8 regiments, of which one was a railway and one a telegraph regiment. These regiments formed 26 battalions, varying from 3 to 7 companies.

The air force had 4 balloon companies and 3 aviation companies; and in addition 10 aeronautical sections and one transport company.

The colonial troops formed 16 regiments of colonial infantry, of which 12 were in France and 4 in the colonies. There were 5 independent battalions and 2 independent companies in the colonies; one regiment of Annam rifles, 4 regiments of Tonkin rifles, 4 regiments and 8 battalions of Senegal rifles, 3 regiments of Madagascar rifles. The colonial cavalry consisted of 2 squadrons of Senegal Spahis, one squadron of natives of Congo and Chari, and one squadron of Indo-China natives. The colonial artillery comprised in France 3 regiments forming 36 batteries, of which 18 were field and 6 mountain; in the colonies were 4 regiments and 2 independent groups. Finally in Morocco there were 6 mixed regiments with 3 battalions, of which one was a colonial battalion and 2 were Senegal rifles.

The French army had 21 army corps, but the XIX. Corps (Algeria) was not, during the World War, brought into the field armies as such. However, 2 African divisions were brought over and attached to the V. Army, so that the troops figured at the front.

The active divisions of the metropolitan army (including 19 corps) were numbered from 1 to 43; some special designations were given to new divisions formed on mobilization from active troops not included in the 20 corps of the metropolitan army present in France. The reserve divisions were numbered from 51 to 75. The designation "reserve" was abolished in 1915. Territorial divisions were given numbers above 80. Higher-numbered divisions were formed by reconstitutions from existing divisions, from 1915 onwards. These had numbers above 100.

The only exterior theatres of war in which France employed large formations were the Dardanelles, Salonika and Italy.

In the Dardanelles campaign the expeditionary force was eventually of about the strength of 2 divisions. These were afterwards regularly constituted as the 156th and the 17th Colonial Divs. At Salonika there were, in addition to the two Gallipoli divisions, the 57th Div. and the 122nd and 11th Colonial Divs., to which were added in 1917 the 16th Colonial, 30th and 76th Divs. In Italy, in the winter of 1917–8, there were 6 divisions detached from the French front, of which 2 remained to the end of the war, being replaced in France by 2 Italian divisions. Smaller forces were employed at Cyprus (1916), and in Syria and Palestine; in the African campaigns; in North Russia, and elsewhere. (V. L. E. C.)

III.—Belgian Army

In 1910 recruiting for the Belgian army was still regulated, under legislation of 1902, on a voluntary basis, completed by drawing by lot. The peace effective strength was 42,800 men, and the effective total of the field army on mobilization was fixed at 100,000 men.

By the statute of 1913 Parliament established the principle that the defence of the home country was an obligation charge on the family. Each family must furnish one son at least for military serv-

ice. This reform placed at the disposal of the army an annual contingent of about 33,000 men. This increased considerably the effectives subject to recall on mobilization, and caused a complete reform of the army organization. The new organization was chiefly instituted from a desire of assuring during times of peace a direct liaison between the two principal arms—infantry and artillery. This was achieved by the formation of a mixed brigade which was formed from a regiment of infantry and a group of field artillery.

On a war footing, under the reorganization now effected, there would be 6 army divisions and one cavalry division. This was the scheme under which the Belgian army found itself involved in war in 1914. It provided for an effective strength of 350,000 men, of which 100,000 were fortress troops; but this would not be reached before 1918, when the recruiting law would have been applied to 6 classes of militia. As in 1914 the total of 8 junior classes recallable to the colours did not provide more than a total of 117,000 men, it was found that the field army, while mobilizing so vast a cadre, yet possessed effective units of extreme weakness only. Further, at the outset of the campaign the infantry units did not count in soldiers but in cadres—or half only of their strength. In fact the war surprised the Belgian army in the midst of reorganization. (1) The order for heavy Maxim machine-guns had only been completed in part; a certain number of companies in the field army were equipped with Hotchkiss machine-guns which were taken from the armament of the fortresses. Owing to the lack of a fixed regimental scale of transport, all machine-guns were carried in requisitioned transport and this paralyzed their use. (2) It was intended that the divisional artillery regiment would have a group of field guns and two groups of 9·5-in. howitzers. When war was declared there existed in the whole army only one group of howitzers; the artillery of the whole army was equipped only with 75-mm. guns. The adoption of a 15-cm. howitzer was still under consideration. (3) The number of cavalry regiments should have been raised from 8 to 12, but only 3 of the 4 new regiments had been created; the cavalry divisions possessed 2 brigades instead of 3. (4) The Air Force possessed a single squadron of one dozen aeroplanes. The infantry were armed with the Mauser rifle of 1889 type, firing an ordinary pointed bullet.

After the battle of the Yser the Belgian army consisted of only 32,000 rifles. This excessive reduction of effectives caused the suppression of the mixed brigades. Each army division consisted of 3 mixed regiments (one regiment of infantry and one group of artillery). The 3rd Div. alone had 3 mixed brigades. It was with this composition that the army spent the whole winter 1914–5. The excess of artillery permitted the placing of 2 regiments of this arm at the disposal of the 27th and 28th Divs. (British) in the Ypres salient.

A few days after mobilization the Government had decreed the calling-up of the 1914 class. This contingent, and voluntary enlistments at the outbreak of war, formed a feeding reserve of 50,000 men, who were at first collected in the depots around Antwerp and later taken to the district of the Pas-de-Calais after the evacuation of that fortress.

In the spring of 1917 the army was reorganized in view of its participation in the general offensive projected by Gen. Nivelle. The number of machine-guns employed was considerably increased. Ignoring a similarity of type of weapon, but keeping to a single type of machine-gun in each division, companies of 6 machine-guns were raised for each battalion of infantry. The adoption of the French light machine-gun at the rate of 6, and later of 9, weapons per company, allowed a reduction of the effectives in the company to about 180 men. As a result it was possible to increase the regiments to 4 battalions of 1,000 men in a brigade of 2 regiments of 3 battalions, each battalion being formed of 3 companies of infantry and one company of machine-guns. Later, the acquisition of a certain number of howitzers permitted each division to possess some fairly heavy material, and created further a brigade of 2 regiments of heavy artillery. Hence the composition of an army division in 1917 was: headquarters; 3 brigades of infantry of 2 regiments of 3 battalions; one brigade of artillery; one regiment of engineers of 2 battalions; one light group of 2 squadrons of cavalry, and one company of cyclists. Thus formed, the Belgian army at the front on Sept. 1 1917 at the period of the British offensive at Ypres, had 168,000 men, of whom 5,700 were officers.

In order to maintain the strength now reached, and to prepare for the normal wastage of stationary warfare, it was decreed by law that personal service was obligatory for all Belgians between the ages of 18 and 40 years living outside the invaded territory.

The Belgian army found itself ready a year later—in Sept. 1918—to join in the offensive attack in Flanders with 170,000 men, despite the fact that 30,000 were serving in the hospitals, in military factories, in munition parks, and other subsidiary services.

The organization of the Belgian military system which developed after the war as a permanent element in the institutions of the country may be summarized here. The royal decree of July 1917 made army service universal and obligatory, but till the end of the war it had been possible to apply it only to those Belgians living in the uninvaded territory, that is to say, to a very small fraction of the annual contingent. Immediately after demobilization it was decided that all men of the classes 1914–5–6–7–8 of the invaded portion of the country who had not served during the war should be called in succession under arms, each military contingent following the other at about 6 months' interval. This measure was in 1921 in process of being carried out.

The term of service with the colours was that ordered by the law of 1912, viz.:—Infantry and engineers, 15 months; field artillery, 21 months; horse artillery, 24 months. However, "breadwinners," *i.e.* the married men or those of good conduct who supported families, were allowed to return to their homes after 4 months of instruction only.

In Oct. 1920 the Minister of War, yielding to the pressure of public opinion which favoured a reduction of military expenses, decided that in the transitory period until the completion of training of the backward classes, *i.e.* until 1922 (having regard to the fact that during this period 2 whole classes would be under arms), the terms of active service were to be reduced for the time being to 10 months for infantry, 12 months for engineers and fortress artillery, 17 months for cavalry and horse artillery.

The Peace and War Organization.—The constitution of "army divisions" (practically equivalent to army corps) is as shown below. Certain modifications, however, were under consideration in 1921 with a view (*a*) to augmenting the number of machine-guns, with the final object of forming a machine-gun battalion per infantry division, (*b*) to developing the technical services, (*c*) to increasing the aviation and the heavy artillery of the army.

Army divisions (6 in number) consist each of 2 infantry divisions and other troops. The infantry division consists of 3 infantry regiments, one artillery regiment, and one engineer battalion. The corps troops, as they may be called, consist of a battalion of cyclists, a regiment of cavalry, a regiment of heavy artillery, and a battalion of engineers.

There is one cavalry division consisting of 3 brigades (each of 2 regiments) with divisional troops (one group horse artillery, one group of motor automatic guns, two battalions cyclists, one cyclist company of engineers).

Army troops not assigned to army divisions are: a brigade of 3 heavy-artillery regiments, an air force of one balloon battalion and 2 aeroplane squadrons, a telegraph battalion, a searchlight battalion, a bridging battalion and a railway battalion. (R. van O.)

IV.—The Russian Army

Under the Imperial Russian Government, the Ministry of War, on its military side, included (*a*) the chief council of the general staff, which controlled all questions relating to the development of the armed forces of the empire and the use of them in the event of war, and (*b*) the general staff itself, which controlled the conditions of military service and the inner life of the army. The chief council of the general staff was only formed in 1905, after the Russo-Japanese War. This allocation of the more important questions to a special body, presided over by the chief of the general staff, was a measure highly important for ensuring the carrying-out of basic reforms and improvements. At first the head of the general staff was exempted from subordination to the War Ministry and reported directly to the Tsar on questions under its jurisdiction, but after 3 years the existence of 2 bodies reporting on military matters was acknowledged to be inconvenient, and the chief council of the general staff was again included in the composition of the War Ministry. In it there were gradually concentrated questions relating to the constitution of the army and the working-out of war plans. The first head of the Russian general staff was Gen. Palitsin, who occupied this position from 1905 to the end of 1908; he was subsequently succeeded by Gens. Sukhomlinov, Mishlaevsky, Gerngros, Jilinsky and Jenushkevitch; the last named was appointed only a few months before the outbreak of the World War. With the advent of war, the troops assigned for military operations were entirely removed from the control of the War Ministry; the control of them was organized according to a special "Order for the control of troops in the field in war time." This order was confirmed by the Tsar on July 16–29 1914, *i.e.* only 3 days before the declaration of war on Russia on the part of Germany. The order mentioned fixed the organization of the higher command, the arrangement of the rear of the troops assigned for military operations, as well as the duties, rights and sphere of jurisdiction of the commands in the field.

The highest troop division in peace time in Russia was the corps. Though the corps often formed part of the military district, this unit had rather a territorial than an operative character; and its commanding personnel served only as the basis for forming the higher commands in war time. The order on command in the field provided for the grouping of the corps in armies, and of armies into larger combinations, called "fronts." The whole of the troops, those

forming the composition of a "front," as well as those remaining in the composition of separate armies and even corps, formed the operating army.

The supreme command of all the forces was, in the event of the Tsar not wishing to assume it personally, entrusted to a supreme commander-in-chief, who had the right to order military activities according to his own independent judgment. No Government institution, nor any person in the empire, with the exception of the Tsar, had the right to give the supreme commander-in-chief orders, or to hold him to account. At the head of a "front" there was a commander-in-chief, and at the head of each "army" a commander, who also enjoyed very extensive responsibilities. The supreme commander-in-chief had to fix his attention mainly on the conduct of military operations. The question of the supply of his troops with all necessities, in the broadest sense of the word, was left to the care of the supply bodies of the War Ministry, who were entrusted with general requirements only. Besides the conduct of military operations, the supreme commander-in-chief retained the higher command in the exploitation of the net of railways in the theatre of military operations, a control which was highly important, in view of Russia's poverty in railways generally. The staff of the supreme commander-in-chief was very limited; it consisted of 45 officers, 10 civil servants and 2 men of medical rank.

The commander-in-chief of a "front" was a man who controlled not only the military operations of his front, but was likewise responsible for the provision of all the requirements of the armies subordinated to him. To make it possible to carry out the second half of his duties there was subordinated to him a part of the territory forming the theatre of military operations with all the materials in that territory; this formed the rear of the army of the given front; everything that could not be procured on the spot had to be ordered, in good time, from the interior of the empire through the supply bodies of the War Ministry. His headquarters consisted of a staff and a series of commands, subordinated to the head of supply, who carried out all the plans of the commander-in-chief relating to domestic administration. The territory composing the rear of the army of the front formed one or more military districts, the commanders of which were subordinated to the commander-in-chief through the head of supply. Lastly, the headquarters of the commander of an army was regarded and organized as the executive organ of operations.

The system created by these regulations did not suffer any material changes in the course of the first two years of the World War. It was only in 1916 that the personnel of the supreme commander-in-chief's staff began to increase; it was found expedient to include in it a whole series of new departments for which no need was felt in the first two years of war.

The basis of the Russian military system was the *regulation relating to military obligation*, which fixed the terms of military service. To turn fully to account one of the main advantages of Russia over the other European Powers, the numerical superiority of her reserve man-power, and also to carry out other improvements, the general council of the general staff elaborated in 1911–2 a new scheme of compulsory service, which was approved by the imperial Duma and the Senate. According to this, military obligation was extended over the whole of a population which counted 150 million, the fit male population (between the ages of 18 and 43) consisting of over 26 million. This was the reservoir on which Russia could depend for the replenishment of her army in time of war. It could have been further increased by calling up the different classes even before their time, as well as by extending military obligations to the different races in the country and to men of over 43, but the two latter methods were difficult to carry out, owing to the conditions of Russian life.

The new organization of the army was completed in 1910. It brought many changes, but was not successful in fully realizing the scheme mentioned, as, in carrying out the fundamental part of the work, two grave limitations were set. These were that the new arrangement of troops must bring no change in the yearly contingent of recruits and in the amount of permanent expenses allocated for the maintenance of the army. These conditions resulted in the infantry being left with 4-battalion regiments and the field artillery with 8-gun batteries. These defects in organization were rectified later, but only during war itself.

The principal reform carried out in the infantry consisted rather in a considerable increase in the numerical composition of the field-infantry units than in a material strengthening of the cadres of the first-line units, who formed the kernel of the army in war time. Machine-gun and communication units were introduced. The recasting of the peace organization of reserve units enabled 7 new field divisions to be created. Lastly, in the formation of the second-line units, with an order for mobilization, the so-called system of "secret cadre" was adopted. Under this system, when the troops passed to a war footing, from each first-line unit there were taken a certain number of officers and men, who formed the cadre on which the second-line units were built up. This system was applied also to the field artillery. The organization of the cavalry and horse artillery remained, on the whole, unchanged. Howitzers were introduced into the field-artillery organization, and a beginning was made with the formation of heavy artillery. In technical resources the army was insufficiently supplied, owing to the lack of credits and the difficulty of manufacturing the necessary materials in home factories.

In the middle of 1914 the Russian army was composed as follows: Of infantry there were 70 field divisions (1st, 2nd and 3rd Guard; 1st, 2nd, 3rd and the Circassian Grenadiers; 1st to 52d infantry; 1st to 11th Siberian), each with 4 regiments of 4-battalion strength; 18 light or "rifle" brigades (Guard; 1st to 5th; 1st to 4th Finnish; 1st and 2nd Circassian; 1st to 6th Turkestan and Kuban-Plastun brigade; 16 light brigades of 4, and 2 light brigades of 3 2-battalion regiments; the Kuban-Plastun brigade had 6 Plastun battalions. In war time there would be formed another 36 second-line infantry divisions (53rd to 85th infantry and 12th to 14th Siberian); in addition, certain infantry brigades of varying establishment would be so formed as to be able to expand into divisions. Of cavalry there were 24 divisions (1st and 2nd Guard; 1st to 15th and Circassian cavalry; 1st and 2nd Cossacks, 1st to 3rd Circassian Cossacks, 1st Turkestan Cossacks), each consisting of 4 (6-squadron or 6-sotnia) regiments, excepting the 1st Guard Div., which had 7 regiments; 8 independent brigades (Guard; 1st to 3rd cavalry; 4th Cossack), each having 2 or 3 regiments; and a few smaller units. In war time the number of cavalry units was not increased; the number of Cossack cavalry units was supplemented by the formation of Cossack units of the 2nd and 3rd class from reserve men. In each infantry division was included an artillery brigade (6-8 batteries); in every light brigade an artillery group (3 batteries). The cavalry and Cossack divisions had attached horse artillery groups of two 6-gun batteries. All the troops mentioned were, in peace-time, formed into 37 army corps (Guard; Grenadier; I.–XXV. Army; I.–III. Circassian; I. and II. Turkestan and I.-V. Siberian). The normal corps consisted of two infantry and one cavalry division. Several corps had no cavalry at all; others had two cavalry divisions and an extra light brigade. In war time cavalry divisions fell out of the corps strength, and were worked as independent cavalry, by divisions. The army corps was supplied with corps cavalry, mostly of Cossack units of the second and third class. On the strength of every corps there was, besides the field-gun establishment, one mortar (howitzer) division of two 4-gun batteries and one sapper detachment. There were also several heavy-artillery units as well as pontoon battalions, railway, transport and air units, which were distributed in war time, according to a special plan, among the armies. Draft-finding units of infantry, artillery and engineers were formed only on mobilization by creating cadres from the corresponding field units. As for the cavalry cadres, draft-finding units were already maintained in peace-time as reserve cavalry regiments and divisions.

All the troops indicated above were not, in peace-time, evenly distributed over the territories of the empire, but were mostly concentrated on the frontiers, on the western frontier in particular. This system of distribution had been in existence from olden times, owing to the lack of railways and a desire to protect the frontiers as much as possible. The system, however, greatly complicated mobilization, as the principal sources for war expansion were nearer to the centre of the empire, and therefore, with an order for mobilization, the necessity arose of carrying out a considerable movement of drafts over long distances. In proportion as the net of railways developed, ensuring a quick supply of troops from the centre to the frontiers if required, one could observe a withdrawal in the permanent quarters of the troops from the frontier regions nearer to the sources for completion. This change was particularly marked in 1910, when 7 infantry and 2 cavalry divisions, with 2 staffs of corps, were moved from the western frontiers to the interior of the empire. This withdrawal aroused alarm at the time in France, and suitable explanations had to be made.

The whole territory of the empire was, for military-administrative purposes, divided into military districts (12 in number), at the head of which was the commander of the troops of the district. The distribution of the corps in the military districts was as follows:—

1. St. Petersburg	M. District	Guard, I., XVIII., XXII. Corps
2. Vilna	" "	II., III., IV., XX. Corps
3. Warsaw	" "	VI., XIV., XV., XIX., XXIII. Corps
4. Kiev	" "	IX., X., XI., XII., XXI. Corps
5. Odessa	" "	VII., VIII. Corps
6. Moscow	" "	Grenad. V., XIII., XVII., XXV.
7. Kazan	" "	XVI., XXIV.
8. Caucasus	" "	I. C., II. C., III. C.
9. Turkestan	" "	I. T., II. T.
10. Omsk	" "	10th Siberian Rifle Div.
11. Irkutsk	" "	II. Sib., III. Sib.
12. Pri-Amur	" "	I. Sib., IV. Sib., VI. Sib.

The local administration in Cossack districts was organized on a special basis. Of Cossack "armies"—*i.e.* autonomous forces—on Russian territory there were 11, namely the Don, Kuban, Terek, Astrakhan, Orenburg, Ural, Siberia, Semerechensk, Trans-Baikal, Amur and Ussuri.

The Russian army was placed on a war footing in 1914 on the "mobilization plan of 1910." A new mobilization plan, revised in certain respects, and known as "mobilization plan No. 20," had been drawn up in 1913, but in July 1914 full effect had not yet been

given to this; it was found necessary to discard it and to carry out mobilization by the somewhat out-of-date plan of 1910.

As every war is usually preceded by a more or less lengthy period of political complications, then, in order to safeguard mobilization, a declaration was previously prepared, called the "period preparatory to war," during which each unit and command was required to overhaul its mobilization scheme and complete any deficiencies, and to recall all ranks on leave or on detachment. This was proclaimed on July 26 1914.

There were in Russia in 1914 the following permanent fortresses or forts:—(*a*) *Land:* Kovno, Olita, Osovets, Lomza, fortifications on the river Narev, Zegrzh, Novogeorgievsk, Warsaw, Ivangorod, Brest-Litovsk, Kars, Kushk; (*b*) *Maritime:* Kronstadt, Viborg, Sveaborg, Libava, Ochakov, Sevastopol, Kerch, Batum, Vladivostok, Nikolayavsk-on-Amur. Modern developments in military engineering had made all these fortresses very antiquated. The profiles of the fortifications were weak and could not withstand the power of the modern gun; camouflage practically did not exist. The artillery was of the most varied and of extremely antiquated types and ammunition was limited. In a condition such as this, the fortresses could not be a support for manoeuvre in the field, nor for that matter for operations at sea; on the contrary, they themselves needed the support of a living force. They demanded considerable numbers for their garrisons, and so further weakened the army in the field. Of the land fortresses, those of foremost significance were held to be the fortresses of Kovno, Osovets and Brest-Litovsk.

In 1914 the quicker mobilization and concentration of the German and Austro-Hungarian armies made it impossible to carry out the strategic deployment of the main forces of the Russian army on the Vistula. Thus, all the forts and fortifications on the river just mentioned, as well as on the Narev, were, to a certain extent, cut off. Their position, combined with the scarcity of means for reconstruction, as well as with the difficulty of carrying on defence from such a populous point as Warsaw and the necessity of providing large forces as garrisons, compelled the abandonment of reconstruction. An exception was made only in the case of Novogeorgievsk, which seemed to have future possibilities as a means of enhancing freedom of manoeuvre on both flanks of the Vistula.

In the case of the maritime fortresses, attention was practically concentrated on Kronstadt, Sevastopol and Vladivostok; Kerch and Libava were suppressed.

In respect of railways Russia was very deficient, notwithstanding the fact that in the years immediately preceding the war several new lines were built, of which the most important, from a military point of view, was the new double-track line Bologoe–Sedlets. Taking the data of 1913, the density of railway lines in European Russia (1 km. per 100 sq.km.) was only one-twelfth of what it was in Great Britain. The amount of double-track lines was also small, altogether about 25% of the whole, when in other European states the percentage was as high as fifty. Rolling stock was likewise limited; to every kilometre there were hardly above 7 carriages, while in other countries of Western Europe it was twice and three times as much.

Macadam roads were sufficiently frequent in the main frontier regions adjacent to Germany, but away from those regions common roads only were available. The front adjoining Austria-Hungary had no macadam roads at all.

The war with Japan had to a large extent used up the military stores that Russia possessed and the provision of new technical resources of war such as heavy artillery, means of communication, motor-cars, wire, machine-guns, air craft—involved the assignment of fresh large credits, and the manufacture of the necessary stores had to be spread over a number of years. Moreover, as industry in Russia was in a poor state of development orders had to be placed abroad and the execution of these was complicated by questions of financial procedure. This state of things resulted in the army, at the beginning of the war, being poorly supplied both with technical resources and reserves of armament. In certain respects the latter were not up to the recognized pre-war standards, low as these sometimes were (*e.g.* 1,000 rounds in reserve per light gun and per rifle).

In the beginning of 1914 the War Ministry had brought before the Legislature a bill for the allocation of credits for the further development of the armed forces, the so-called "great programme." The bill provided for the further strengthening of the cadres in the infantry and artillery, the supply of the army with heavy artillery in a larger proportion and the creation of new units which would be formed into two new corps. The bill was passed, but the advent of the war prevented its provisions from being actually carried out. (Y. D.)

It is not possible to follow out in detail the development of the Russian army after the mobilization of 1914. The strength of the armies of the N.W., W., and S.W. "fronts," at different periods, is given by Gen. von Falkenhayn as follows [1]:—

Combatants only

Mid Sept. 1914	950,000
End Dec. 1914	1,688,000
End Jan. 1915	1,843,000
End April 1915	1,767,000
End May 1916	2,240,000

The last date may be considered as the high-water mark of Russia's military effort. In spite of the enormous losses in men, material and territory of the campaign of May–Sept. 1915 Russia placed in the field for the combined Allied offensive of 1916 half a million more combatants than at any previous date.

The great Galician offensive was launched in June 1916. Its brilliant successes were won at very heavy cost, notably in the battles about Kovel. The effort died away into trench warfare. The Rumanian defeats stimulated a fresh spasm of activity in the winter of 1916–7, but the spring revolution of 1917 found the mass of the army, no less than the people at large, war-weary and dispirited by great sacrifices which seemingly brought peace no nearer.

As is well known, the main contributory cause of the disasters of 1915 was shortage of ammunition, and it was only by the expenditure of lives instead of material that the Russian command was able to limit, as it did, the consequences of these disasters. What is less well known, but historically almost as important, is the fact that even in 1916 the material equipment of the fronts was at a low level. The victories of that year were won by the same methods as those which stemmed the tide of defeat in 1915—ruthless expenditure of lives. A great effort to remedy material deficiencies had indeed set in at the eleventh hour. Between July 1915 and the end of 1916, the ill-developed industries of Russia were revolutionized—the Tula rifle factory, for instance, having an output in 1916 six times as great as its output in the year of the war with Japan, besides turning out 1,140 machine-guns per month. At one period the output of gas shell was comparable to that in Great Britain. Owing, however, to the immense extent of the front, even the utmost possible developments of Russian industry would not have sufficed, and assistance from Great Britain and France was necessary to supplement it. This assistance, taken together with home output and the aid of America, as an ally, would probably have placed the Russian army on a satisfactory basis as regards equipment by the early autumn of 1917. But before the home effort could bear fruit and Allied assistance was available, the strain on the army had become too heavy.[2]

In the conditions, the disintegration of the Russian army which followed the spring revolution of 1917 scarcely requires explanation. An iron discipline, far more inflexible than that of any army of Western or even Central Europe, had been strained to the utmost, when its foundations suddenly crumbled, and the chance of creating a new discipline, such as was created by Carnot in the French army of 1793–4, was let slip in the chaos of conflicting ideals and policies which constitutes the tragic history of 1917, both inside and outside Russia. The last effort of the old army, the Galician offensive of July 1, for a moment shook the solidity of the Austro-German defence. But once more Germany was able to transfer troops (14 divisions) to the East, for the French offensive had collapsed and the *moral* of the French army was passing through a crisis which compelled inaction. This time the German command determined to finish matters in the East. First-quality divisions, employed on well-chosen parts of the front and using new methods of attack, closed the history of the eastern-front campaigns in the battles of the Sereth (July 19) and Riga (Sept. 1).

During 1918 the final dissolution of the old army completed itself in the civil wars. The original military forces of the Soviet Government were a militia—the so-called Red Guard; this was replaced gradually by a regular army. But neither the "Red Army" nor the armies raised by the different counter-revolutionary leaders, derive directly from the imperial army. Thousands, perhaps hundreds of thousands, of individual ex-officers and ex-soldiers figured in these new organizations and imparted to them the routine practices, the uniforms, and many of the characteristic customs of the old army. But no organic continuity exists between old and new. The peace of Brest-Litovsk and the civil wars constitute not a new chapter but a new book in the history of Russian military institutions.

No detailed information is available as to the losses of the Russian army from 1914 to the peace of Brest-Litovsk. The most probable estimates give 1,700,000 dead and 2,500,000 prisoners as "definitive" losses, *i.e.* exclusive of wounded, but in the absence of the data from which those estimates are built up, all that can be said is that Russia lost more heavily in men than any other belligerent on either side. (C. F. A.)

[1] No information is available as to the total ration strength of the Russian armies at different periods of the war, nor of the combatant strength of the forces on the Caucasus-Persia front.

[2] The contrast between Eastern and Western standards of armament may be illustrated by comparing the French artillery strength at the battle of the Somme (July 1 1916) and the Russian artillery strength at the battle of the Strypa (Yastoviet) on June 6 1916, both being deliberately prepared offensives against an entrenched front:—

Somme	Frontage of VI. Army	10 m.	444 field guns	645 medium and heavy guns and howitzers
Strypa	Frontage of II. Corps	14 m.	160 field guns and howitzers	23 medium guns and howitzers

V.—Italian Army

At the outbreak of the World War the Italian army was in a very unsatisfactory condition. Political leaders, and Parliament and public opinion generally in Italy, had for years held the view that the era of great wars was past, and that in any case pacific intentions gave a practical assurance of peace. For this reason it was judged sufficient to have an army which was strong enough to preserve order in the country and give to foreigners the impression that Italy was not completely disarmed. As a consequence the State had neglected the army, and its efficiency in comparison with those of its neighbours, to which continued attention had been paid and on which expenditure had continually increased, had been gradually diminishing. In 1907, however, the Government of the day had been induced to nominate a commission to study the faults and gaps in the military organism and suggest means to remedy them. In 1910 this commission had presented a programme fitted to the financial capacity of the country and its ideas; that is to say, a very modest scheme. But the Government found that the proposals were excessive and decided to adopt a reduced programme. And, as if that were not enough, the Government was so slow in carrying out this programme that in 1914 it was not yet completed. It was in April of that year that Gen. Porro refused to go to the Ministry of War unless a new programme were adopted, involving the expenditure of 600 million lire, spread over a period of six years. The programme was cut down by two-thirds and Gen. Porro declined the war portfolio.

In 1911 the Italo-Turkish War broke out. In the course of the war only two classes of reservists were called up, and as a result the units which were mobilized could not fill up with their own reservists. They were brought up to strength with men belonging to classes already under arms, and taken from units remaining in Italy, whose strengths were thus reduced to a miserably low level. Owing to the notable deficiency of the material detailed for mobilization the same system had to be followed in order to equip and refurnish the mobilized units. As a result the stocks in Italy were quickly reduced to a level quite inadequate for general mobilization. Little was done subsequently to fill the gaps, so that these remained.

The Army in August 1914.—The situation of the Italian army at the beginning of Aug. 1914 was as follows. Its financial resources were very limited. The estimates for the year 1914–5 provided 428 million lire (£17,120,000) which included not only ordinary maintenance expenses, but extraordinary expenditure for the rearmament of the artillery, for fortifications, etc.

All citizens were liable to military service for 19 years, from the 20th to the 39th year. They were divided into three categories, and only those belonging to the first category underwent the full term of service (two years). Men of the second category received a few months' instruction. Men of the third category received no instruction at all, and were destined for "third-line" service, even if they belonged to young classes. At the outbreak of war in 1914, owing to the large proportion of recruits yearly passed to the third category, there were in Italy, out of the total number of those of military age and fit for military service, only 1,400,000 men who had received military training. The rest, some 1,600,000 men, had received no military instruction of any kind.

The whole number of citizens liable to military service was divided, mainly according to age, between three organizations: permanent army, mobile militia, and territorial militia. The permanent army was composed of units existing on the peace basis. In peace-time it was composed of professional officers and non-commissioned officers, and of men of the first and second categories.

The force on the estimates for the financial year 1914–5 consisted of 14,000 officers and 275,000 men. The number of permanent officers was insufficient even for peace requirements. Reserve officers were taken from among the recruits of the levy who had passed certain examinations and who applied to serve as officers. They underwent regimental courses, and those taken completed their service as officers. Permanent and reserve officers together fell short by 13,000 of the number required for general mobilization. The greatest shortage was among the artillery officers, who could only total 56% of the number required, and the sanitary services, who were more than 50% short. Professional non-commissioned officers were almost entirely lacking. The law passed in 1910 in the hope of securing an adequate supply had not had the result hoped for. Most of the few who had adopted the army as a career were employed on special service outside the units.

Strengths were very low, so that the smaller units had barely sufficient troops to assure the performance of the ordinary everyday duties of barrack or field life. The troops, and especially the infantry, were continually employed in police duty; units were often split up into small detachments; drafts had to be furnished for Libya. In the circumstances it is easy to understand how complete and systematic training was impossible. Combined training of all arms was out of the question for a great part of the army, the troops of the various arms being stationed in such a way that whole divisions had neither cavalry, artillery nor engineers in their districts.

Owing to the low strengths, the units of the permanent army, in order to reach a war footing, had to incorporate a large proportion of reservists. As the trained reservists of each class were relatively few in number, many classes of reservists had to be incorporated on mobilization. In this way the units had to be completed with men at once older and less recently trained than was the case with the armies of France and Austria-Hungary. Complete mobilization in Aug. 1914 would have meant calling up no fewer than 13 classes.

The mobile and territorial militia units were intended to be formed at given centres, on mobilization, from reservists only. The number of these units and their character was to be decided according to requirements, by royal decree. The mobile militia was designed to operate with the permanent army, but to perform more modest duties than the permanent units. In order to facilitate its organization in case of need, it was decided in 1910 to maintain in peace-time, attached to every line regiment, Alpine battalion and field-artillery regiment, a permanent mobile militia nucleus, to fill up with reservists in case of war and so form the new units. But in 1914 many of these nuclei were not yet formed, and the others were at such low strength as to constitute a mere pretence. Mobile militia units were very rarely embodied for training in peace-time, so that, everything considered, it would have been necessary to improvise the whole organization. In the case of the territorial militia, destined for use on lines of communication or for duty at home, there was still less preparation; units were practically never embodied in peace-time.

Armaments were deficient both in quality and quantity. The infantry had an excellent rifle (1891 model), but the reserves and the output of the factories were not sufficient to meet the probable requirements of war. Machine-guns were almost entirely lacking. Only a few regiments had one section of two guns. Many artillery regiments were still armed with the old "rigid" gun. About 100 batteries had been armed with the Krupp 75-mm. Q.F. (1906 model), but before rearmament was completed it had been decided to adopt a new pattern (Deport 75-mm. 1911 model), and these were not yet ready. A considerable part of the mountain artillery was also unprovided with a quick-firing gun. The programme of 1910, providing for 40 batteries of heavy field artillery, had not been completed. Twenty-eight 4-gun batteries of 149-mm. field howitzers were all the heavy field artillery available. The siege train consisted only of a few big guns and 134 medium guns, generally of an obsolete pattern. The supply of ammunition was scanty. Motor transport was deficient.

The supply of uniforms, equipment, material for artillery and engineers, as well as for sanitary services, was lacking in quantity and quality. To sum up, the condition of the Italian army at the outbreak of war was as follows. The permanent army was lacking chiefly in instruction, machine-guns, heavy field artillery, siege train and material for air warfare. Strengths were very low, and the army had to mobilize with a very high percentage of reservists. Officers, both active and reserve, were too few, and there were scarcely any permanent non-commissioned officers. The units of mobile and territorial militias had to be altogether improvised, with the same bad results—but on a larger scale—as in the case of the permanent army. There was an enormous deficiency of animal and mechanical transport, of ammunition and of material of all kinds.

The Neutrality Period (Aug. 1914–May 24 1915).—Up to May 24 1915, when Italy joined in the war, an intense activity was displayed to make up the deficiencies of the army and enable it to meet with success its traditional foe. Rapid courses for officers were established in the recruiting-schools whereby the number of subaltern officers required to meet the immediate needs of the mobilized army was obtained. On Aug. 1 1914, three classes were with the colours, those of 1892 and 1893—the two levies in course—and the 1891 class which had been recalled for service. On Aug. 8 the 1889 and 1890 classes were called up; on Sept. 7 the young 1894 class, and in Jan. 1915 the 1895 class. Thus the force under arms was 700,000 men. Other classes were called up later on, but with certain limitations as to categories, employment, etc. Reservists were not called up by public notice but by individual summons. Thus existing units were strengthened and new ones formed. Progressively, all the army, army corps, and divisional commands were formed side by side with the territorial commands already in existence. The latter continued to discharge their duties with the staff allotted to them for the period of the war. Provision was made with regard to staff and material required for the establishment of the principal offices charged with the various services.

Several regiments of the permanent army, provided for by the 1910 programme but not yet formed (chiefly field artillery), were organized. The majority of the mobile militia units provided for

were formed, with this important innovation that, instead of incorporating the comparatively old reservists, they were formed of levy men and young reservists, viz. with the same elements as the permanent army. This measure practically meant the suppression of the mobile militia, especially as the reservists destined formerly to the militia were assigned indiscriminately to all first-line units. Finally, the air-service units were, one may say, actually created.

The number of machine-guns and of small and medium calibre guns was increased, and the conditions of the siege train were improved to some extent. Means of transport, ammunition, and sundry other material were greatly increased by bringing up to a maximum the output of the military factories and by placing big orders both at home and abroad. In this way the most striking deficiencies of pre-war times were as far as possible made good.

But this was not all. From the very beginning of the neutrality period units were stationed along the frontier "in advanced occupation," and later on were grouped together under commands of the larger units which had been formed in the meantime.

It may be said, therefore, that when mobilization was officially announced (May 23 1915) a large portion of the army was already mobilized and assembled at the frontier. The mobilization of auxiliary services was, however, much belated in comparison with that of the combatant troops. This was due to causes connected with *matériel* as well as to the fact that the reservists detailed to such services could not be called up at so early a date. The mobilization plans existing in 1914, which presupposed conditions of forces and *matériel* quite different from those in which the army actually found itself, had to be modified substantially during the neutrality period. At the same time the troops underwent a continuous and intense training which remedied in part former deficiencies, especially among the reservists, and imparted the first lessons of the war which had already been fought for months on the Allied fronts.

Notwithstanding all this, in May 1915 the Italian army was not yet in an ideal condition as regards numbers and *matériel*. There were still serious gaps in the number of officers, in the supply of machine-guns and of artillery, as well as in the engineers, the Air Service, etc. The responsibility, however, of this state of things cannot attach to those who reorganized the army during the neutrality period; for they had not only to prepare, in many cases they had to create from nothing. The state in which the army had been left for so many years could not be remedied in ten months.

From May 1915 to November 1918.—The momentous work accomplished during the neutrality period did not cease when the war began, but continued in ever-increasing proportions while the army was engaged in fighting. The military authorities, efficiently supported by Government and nation, not only succeeded in filling up the gaps caused by losses and in remedying the deficiencies shown by the army in 1915, but strengthened it in men, weapons and material, and formed numerous new units and special troops instructed in the use of modern means of warfare. The magnitude of the effort on the part of army and nation appears more evident when one takes into consideration the enormous loss of men, animals and material which Italy sustained during the retreat of Oct. 1917 (Caporetto), and which had to be covered most rapidly. In that unfortunate event the army lost in round figures 8,500 officers, 300,000 men, 70,000 horses and mules, 3,100 guns (among which were two-thirds of all her heavy guns and half of the medium calibres), 1,700 trench mortars, 3,000 machine-guns, 2,000 machine-pistols, about 1,000,000 rifles, 22 aviation parks, 1,500 motor lorries, an enormous number of motor-cycles, etc. It follows that, when examining the data relating to the Italian army in Nov. 1918, it must be borne in mind what that same army had lost a year before. It can then be realized that Italy's effort has been a double one and that her army has to a great extent been formed twice.

According to pre-war provisions, the Italian army consisted of 19 classes. During the war, however, by calling up the younger classes and keeping the older ones, the number of classes with the colours was increased. At the moment of the Armistice the army included 27 classes (from 1874 to 1900). The oldest men were 44 and the youngest 18 years old. These classes gave a total of 5,200,000 men, who at the beginning of Nov. 1918 were made up as follows:—2,500,000 in the army operating in Italy, in the Balkans and in France; 1,200,000 belonging to units, and detailed for services, in the country; 1,500,000 losses (killed, discharged for wounds or sickness, prisoners). During the war no account was taken of the distribution of men as fixed by the old law in 3 categories and 3 army lines; all the men formed one single mass, and were distributed as follows:—in the war zone, 21 classes, that is, men from 19 to 39 (these classes were detailed, according to age, to the first line, to the services of the first line, to the second line and to the services of the second line); on service between the war zone and the country (lines behind the army), 3 classes, that is, men of 40, 41 and 42; in the country, 3 classes, that is, men of 43 and 44 and recruits of 18 who were being trained for service. The provisions which contributed principally to increase the number of drafts from each class were the adoption of a lower standard of physical fitness for military service and the consequent revision of all those who in the years preceding the war had been declared unfit for service.

The supply of drafts was provided for in the following manner. Up to the beginning of 1917 men called or recalled to colours, or returning after medical treatment, were instructed or assembled in the depots from whence they were posted direct to the fighting units. At the beginning of 1917 each infantry brigade was given a reserve battalion from which gaps in the battalions of the brigade were filled up. The reserve battalion was, in its turn, replenished by march units detailed in the war zone (battalions, regiments, brigades) which received men from hospitals, etc., or from the interior of the country. During the last year of the war matters were so arranged that the men, however restored, returned to their own unit through the above-mentioned channel. This system was applied also to the Bersaglieri, to the Alpine troops, and to the infantry machine-gunners. The supply of drafts to other arms and to the various services continued to be secured under the system in force previous to 1917, that is, from the depots in the country. The scarcity of officers, especially of experience, with which the army entered the campaign, was continually aggravated by losses, and was felt during the whole period of the war. The gaps in the higher grades were filled by promotion, and the Italian army soon secured a prominent place among the belligerent armies in respect of the youthfulness of its generals. A certain number of battalion, company or battery commanders were taken from the cavalry officers. Vacancies in the lower grades were filled by means of rapid courses with the corps, the big units, and the recruiting schools in the country. Towards the end of the war only the latter system of recruiting was resorted to, and participation in the courses, which was first voluntary, became compulsory for all those who had gone through a certain curriculum of study.

When the army began its campaign it consisted of 14 army corps, 25 divisions of infantry, 4 divisions of cavalry, all in Italy. Its maximum strength was reached in Oct. 1917 with 26 army corps, of which one was in Albania; 65 divisions of infantry, of which 2 were in Albania and one in Macedonia (the Macedonian division consisted of 4 brigades and had therefore the strength of a corps); 4 divisions of cavalry. At the end of the war the army consisted of 24 army corps, of which one was in Albania and one in France; 57 divisions of infantry, of which 3 were in Albania, one in Macedonia and 2 in France; 4 divisions of cavalry. The army corps were grouped in a number of armies which increased from 4 at the beginning of the war to a maximum of nine.

The infantry strength at the beginning of the war was 560 battalions; on Oct. 1 1917 it was 800 battalions; on Oct. 1 1918 it was 700 battalions. The infantry battalion at the beginning of the war consisted of 4 companies, or 1,000 men, armed only with rifles. The few machine-guns available had been allotted to the regiments, generally 2 guns per regiment, rarely four. At the end of the war each battalion consisted of 3 companies of rifles (each with 2 machine-pistols), one company of machine-gunners (with 8 heavy machine-guns), one section of bombardiers (with 4 Stokes mortars, or 4 torpedo mortars), one section of sappers. The total strength of the battalion was 780 men.

While each battalion was transformed, each regiment was allotted a section of 37-mm. guns and a section of flame-ejectors.

Each brigade received two companies of heavy machine-guns, while four were assigned to each division. Taking into account only the heavy machine-guns, the infantry started the campaign with about 700 machine-guns. On Oct. 1 1917, these had increased to 7,000, and on Oct. 1 1918, to 12,000. In 1916 special Alpine battalions were formed, all consisting of men on skis, clothed and equipped in white and organized so that they could act independently, but they were not given many opportunities for action on skis. In 1917 assault groups were formed consisting of "arditi"—young and very active men who had undergone a most intense and severe training in gymnastics, bomb-throwing, and marching behind artillery or machine-gun barrage. These groups formed a splendid and characteristic attacking force used chiefly for surprise actions and desperate raids. Each group was of practically the same strength as an infantry battalion, but had a larger number of machine-guns and machine-pistols, and a few flame-ejectors. The "arditi" were armed with carbine, dagger and hand grenades. Each army corps had its own assault group and in 1918 a special army corps consisting exclusively of "arditi" was formed. In the same year each infantry regiment formed its own assault platoon (*plotone d'assalto*). During the war the infantry formed 17 groups of automachine guns each consisting of 4 or 6 guns and 5 companies of motor machine-guns each having 6 guns. No tank units were formed because the nature of the Italian front did not call for their use.

The most important transformation undergone by the cavalry during the war was the dismounting of two divisions which were used on the Isonzo and Carso fronts from the spring to the end of 1916; later on these divisions were mounted again. In the earlier stages of the war the cavalry supplied its machine-gun sections to the infantry. With its surplus reservists it furnished afterwards dismounted machine-gun companies which were used at the front.

In May 1915 the field artillery was the best armed among the different special corps and, therefore, underwent less and minor modifications. At the beginning of the war there were 360 batteries of 4 guns, on Oct. 1 1917 there were 440 batteries of 4 guns, on Oct. 1 1918 there were 490 batteries of 4 guns. No change was made with regard to the guns—the 75-mm. 1906 model and the 1911 model of the same calibre. Both guns were of the deformation pattern. The

1911 model had a carriage which when in position opened into two, allowing of important changes of target without moving the gun. This was a great advantage in view of the broken nature of the ground on the Italian front. Guns were drawn by animals, but at the time of the Armistice there were two regiments with guns on motor carriages. The mountain artillery and mule batteries were both supplied with light dismountable guns carried on mules. At the beginning of the war the mountain batteries, served by numerous men and animals and abundantly equipped, were armed with the modern 65-mm. gun and employed in the Alpine districts, generally remaining in position; while the mule batteries, much less complex than the others, were armed with the rigid 70-mm. gun, and used in the plains or in hilly country, accompanying the infantry. Gradually, however, these batteries were equipped with the 65-mm. gun and the difference between the two kinds of batteries disappeared. In 1918 they had become of the same type. When Italy entered into the war there were 60 mountain batteries of 4 guns, and 20 batteries on mules of 4 guns. On Oct. 1 1917 there were 90 mountain batteries of 4 guns and 80 batteries on mules of 4 guns. On Oct. 1 1918 there were 170 batteries of the single type.

At the beginning of the war the heavy artillery was so scarce that it could not be assigned to any army corps, but was scattered, sometimes in single batteries, along the more important sectors of the front. It was armed with the 149 A howitzer, deformation pattern, with animal transport. Later on it was furnished with 105-mm. guns, also drawn by animals, and with 102- and 105-mm. guns drawn by motors. This innovation together with an increase in the number of 149-mm. howitzers made it possible, at the end of 1917, to allot to each army corps a mixed group of 149 A howitzers and of 105-mm. guns (two groups of three batteries) drawn by animals. All the groups drawn by motor and some of the others were left at the disposal of the supreme command. Towards the end of the war a group of three batteries of 149-mm. howitzers was assigned to each infantry division. The heavy field artillery consisted, on May 24 1914, of 30 batteries of 4 guns; on Oct. 1 1917, of 200 batteries of 4 guns; on Oct. 1 1918, of 280 batteries of 4 guns.

At the outbreak of the war the siege train was absolutely insufficient, both in quantity and quality. This state of affairs was improved by transporting to the front the majority of the guns—mostly of ancient pattern—belonging to fortresses, and by placing big orders with home factories. Thus the number of guns was increased and the obsolete batteries were replaced. At the same time the batteries were supplied with motor tractors. From the beginning of 1917 a well-supplied park of tractors was formed. After Caporetto, where a great portion of the old material was lost, the guns were replaced by modern guns made in Italy and in the Allied countries, and new complete permanent groups of guns of the same type were formed, while previously these groups were variable. The principal types of siege artillery in use at the end of the war were guns of 381, 155, 152, 149 and 120 mm.; howitzers of 305 and 152 mm.; mortars of 260 and 210 mm. Besides these, smaller calibres of antiquated patterns were used as fortress artillery. At the outbreak of the war the siege artillery consisted of 40 batteries; on Oct. 1 1917, of 750 batteries; on Oct. 1 1918, of 830 batteries. The siege batteries of big and medium calibres had from 2 to 6 guns each; those of small calibre had 8. On Oct. 1 1918 the total number of big- and medium-calibre guns was 2,550.

There were no anti-aircraft guns at the beginning of the war, and for some time field and mountain guns were adapted for use as anti-aircraft artillery. Later, batteries of 75-mm. guns mounted on motor-cars were formed, and the defence against enemy raids was organized. The anti-aircraft artillery consisted of 100 guns on Oct. 1 1917, and 130 on Oct. 1 1918.

Trench mortars (*bombardes*) were a creation of the war, their original object being to destroy wire entanglements by their curved trajectory and heavy bursting charge, and they proved most successful at the battle of Gorizia in 1916, after which their number and efficiency were greatly increased. During the retreat of Caporetto the bombardiers had to abandon, for lack of transport, nearly all their mortars and they were, therefore, temporarily grouped in a division which fought with the infantry; but as new material became available their battalions were reorganized. The principal mortars used were the 58 A, 58 B, 240 C, 240 L and 240 LA, formed into batteries or groups. On Oct. 1 1917 the batteries numbered 200 and as many autonomous sections; each consisted of 6 to 12 mortars.

To sum up, the Italian artillery was enormously strengthened, from the beginning of the war onward, in number and quality of guns and by the formation of new specialties. Its organization was also improved. The campaign was entered into with a little more than 500 batteries, that is, less than one battery for each infantry battalion. On Oct. 1 1917, there were nearly 2,000 batteries, or 2½ batteries per infantry battalion. During the retreat of Caporetto 3,100 guns and 1,700 bomb-mortars were lost (something over 1,000 batteries). Nevertheless, on Oct. 1 1918 the army had more than 2,000 batteries.

The corps of engineers also was increased in numbers and transformed during the war. The sappers at the outbreak of hostilities were formed into companies; each infantry division had one company with a pontoon section and a telephone section. Later on battalions of sappers were formed of 3 companies each (one of which with pontoon section), and a battalion was assigned to each infantry division, other units doing telephone service. On May 24 1915 there were 42 companies, on Oct. 1 1917, 72 battalions (223 companies), on Oct. 1 1918, 78 battalions (234 companies).

During the war the following special corps were formed:—telpherists; motorists detailed to the numerous drilling-machines used on the front, for digging caves, trenches and ways of communication in the rocky districts; gas specialists, whose chief duty was to examine and make experiments on the use of gas and the means of protection against it; flame-throwers, or detachments furnished with heavy flame-ejectors of position.

One may say that the aeronautical service, especially as regards aviation, was created during the war, at the beginning of which the army had only 24 squadrons of aeroplanes with about 60 machines fit only for observation purposes. Later on, thanks to the enormous increment of the home industry, the number of the machines was increased, and different groups for raids, chasing and observation were formed. In 1918 there were 51 groups with 1,400 machines. The balloon parks increased from 10 to 39. Airships varied as to type; but their number was always limited to six.

The medical service consisted originally of only 800 medical officers of the permanent army. Numerous officers of the reserve were drafted and new officers commissioned so that the total number reached 9,100. Field and other hospitals allotted to the fighting units increased from 300 to 500, to which should be added those of the Red Cross and of the Knights of Malta, as well as the up-to-date surgical and other establishments scattered along the front. Trains fitted for the transport of sick and wounded were increased from 36 to 74. Medical establishments within the country rose from 75 to 1,500 and the number of beds from 90,000 to 400,000.

Motor transport was enormously developed during the war, in consequence not only of the ever-increasing requirement of the war operations but also of the deficiency of animals. Motor traction was used for artillery, camp kitchens, pontoon equipment, etc. On Oct. 1 1918 the officers numbered 3,000, men 130,000.

Losses.—The first preliminary calculations of the losses suffered by the Italian army during the World War made immediately after the Armistice gave the following results in round figures:—Dead, 460,000, of which number 330,000 died on the battlefield or in consequence of wounds, 85,000 died of sickness, 45,000 died while prisoners; wounded, 900,000 and sick, 2,400,000, of whom 2,430,000 had resumed service, 300,000 were under treatment and expected to recover, 570,000 were invalided and permanently unfit for service.

The severest losses were sustained in 1917. The other years followed in this order: 1916, 1915 and 1918. The number of dead given corresponds to 1·27 % of Italy's total population in Jan. 1915 (36,000,000). Subsequent more accurate calculations proved that the actual losses had been underestimated. Senator Giorgio Mortara in his *Prospettive economiche*, published in 1921, quotes the following figures:

Killed on the battlefield	317,000
Died in hospital of wounds	51,000
Died in hospital of sickness	106,000
Prisoners who died of wounds	10,000
Prisoners who died of sickness	80,000
Total	564,000

This gives a percentage of dead to population of 1·56.

If one adds to the above total 25,000 released sick prisoners who died during the period of demobilization, and 62,000 who died of disease during the same period, the number of deaths rises to 651,000.

A revision and control of data dealing with losses was in 1921 being attended to, but the partial results already then known led to the belief that the first set of figures given was far inferior to the reality, and that even those given by Senator Mortara would have to be increased rather than diminished.

Demobilization.—On the cessation of hostilities the army began the reduction of its forces to something approaching pre-war strength. Demobilization could not be immediate or rapid owing to the necessity of keeping sufficient troops on the Armistice line and in foreign territories; of having many troops under arms in the country to repress the disorders likely to occur after such a war; of regulating the discharge of troops in accordance with means of transport available, taking into account also the probability of emigration on the part of some of the men discharged and the possibility of employment at home for others. It was also advisable to keep numerous units in the redeemed territories to employ them in urgent works of reconstruction. These and other considerations imposed a gradual demobilization of men as well as of animals and material. Demobilization involved not only a reduction but also a transformation inasmuch as the army had to be organized on lines different from those of 1914 and in accordance with the lessons of the war.

The older classes of reservists were discharged first. The men were given an insurance policy, a parcel of mufti clothes or a corresponding sum of money and their fare to return to their residence in Italy or abroad. Officers were discharged after the men of their class. Medical officers especially were kept in the army to attend on wounded and sick men and prisoners returning from internment. By the end of June 1919, 14 classes had been discharged as follows:—

classes 1874 to 1876 in Nov. 1918; classes 1877 to 1884 in Dec. 1918; classes 1885 and 1886 in March 1919; class 1887 in April 1919. The 1900 class—which was the last called up during the war and which had not fought—was discharged on leave and called up again at the end of 1919 and the beginning of 1920. With the discharge of these classes, and with that of other special categories of the younger classes, the total number of men with the colours, which in Nov. 1918 exceeded 3,500,000, was reduced on July 1 1919 to about 900,000, of whom 72,000 were in the colonies, 54,000 in Albania, 27,000 in Macedonia, 9,000 in Asia Minor, 7,500 in France, and 2,000 in Russia. By the same date 225 generals and 76,000 other officers had been discharged.

During the latter part of 1919 nine other classes were discharged, as follows.—class 1888 at the end of June, class 1889 at the end of July, classes 1890 to 1892 at the end of Aug., classes 1893 and 1894 at the end of Sept., class 1895 at the end of Oct., class 1896 at the end of December. Immediately afterwards men belonging to the pre-war second and third categories of classes 1897 to 1899 were discharged, so that at the beginning of 1920 the Italian army consisted only of men of the first category of 1897, 1898 and 1899 classes. At the same time 130,000 reserve officers out of the 165,000 in service at the time of the Armistice had been discharged. The principal reductions in the different units of the army up to the beginning of 1920 consisted of the breaking-up of 5 commands of army, 21 commands of army corps, 45 commands of infantry division, one command of cavalry division, 31 infantry brigades, 6 brigades of bersaglieri, 49 Alpine battalions, 12 squadrons of cavalry, 180 field batteries, 80 mountain batteries, 105 heavy field batteries, 600 siege batteries. All the men of the 1897, 1898 and 1899 classes were discharged in Feb. 1921, when only the 1900 and the 1901 classes (the latter had been called up in Nov. 1920) were with the colours. By this date the last men who had fought in the World War had left the army.

VI.—United States

In 1911 the actual strength of the U.S. regular army was 4,888 officers and 70,250 men, of whom 56,753 officers and men were stationed in the United States. Deducting the coast artillery, there was left, in the United States, a mobile army of only 31,850 officers and men. This small force was distributed among 49 army posts in 24 states and territories with an average strength of 700 men to each post, only one post having a capacity for a brigade. The result was a regular army extraordinarily expensive to maintain, the separate units of which had no organization higher than the regiment. There was no opportunity for manœuvres on a large scale, little opportunity for the joint training of the several arms, and no practical experience for the officers of the staff-work and leadership necessary to the handling of larger commands. A partial concentration of troops on the Mexican border in 1911 gave the U.S. army its first opportunity for a division manœuvre.

Under the Act of 1901 the National Guard of the different states had been assimilated to the regular army in organization and equipment, and was receiving financial assistance from the Federal Government in the shape of equipment and pay for manœuvres and the loan of officers from the regular army for training. In 1911 this force was in far better condition than it had been at the outbreak of the Spanish-American War (1898), but it was still locally organized, was made up of men whose military association and activity were merely an incident added by interest and preference to their ordinary civilian occupation, and was affected by traditions and associations based upon state rather than national service. In 1911 the reported strength of the National Guard was 117,980 officers and men, and an Act of Congress authorized the president to increase the army establishment so as to provide 200 officers of the active list of the regular army for duty as inspectors and instructors of the organized militia and National Guard.

Reorganisation of 1916.—Successive Secretaries of War had vainly urged upon Congress the necessity of a reorganization of the regular army on the basis of larger tactical units. In June 1916 there was finally passed and approved the bill known as the National Defense Act. This provided for an increase of the regular army to a total not to exceed 11,450 officers and 175,000 troops of the line, including the Ordnance Department, 42,750 non-combatant troops and unassigned recruits, and 5,733 Philippine Scouts, in all about 235,000 officers and men. The number of regiments was to be increased to 65 of infantry, 25 of cavalry, 21 of field artillery, 7 of engineers, with an additional 2 battalions of mounted engineers. These increases were to be carried out by July 1921 and five annual increments, but the President was authorized, in case of emergency, to put them into immediate effect. The general officers of the line were increased in number from 7 to 11 major-generals and from 17 to 36 brigadier-generals to provide the necessary general officers for the contemplated divisions and brigades and higher staff appointments. The period of enlistment in the regular army was altered to 3 years with the colours and 4 in the reserve. The National Defense Act also provided for bringing the organized militia of the several states into a single national guard, the entire expenses of which were assumed by the Federal Government. It was estimated that this force would ultimately reach in peace-time a strength of 17,000 officers and 440,000 men of all arms, so apportioned that when assembled at the call of the Government it would constitute 16 divisions. The Act further authorized (*a*) an Officers' Reserve Corps, to be selected, trained and commissioned in time of peace for use in war only, up to and including the grade of major, and (*b*) an Enlisted Reserve Corps, specialists for the technical departments of the army, to be recruited in time of peace for use in war only.

The General Staff Corps.—Before 1903 the American army had possessed no general staff. Since the early history of the country there had been a commanding-general of the army and a system of semi-independent War Department bureaus, loosely coördinated either with each other or with the line of the army, and there had always existed uncertainty and dispute as to the respective functions and authority of the Secretary of War, the commanding-general and the bureaus. In Feb. 1903 a Congressional Act abolished the office of commanding-general and created a General Staff Corps, to be composed of 45 officers, with a chief-of-staff who, under the direction of the President and the Secretary of War, was charged with the supervision of all troops of the line and all the War Department bureaus. In actual practice, however, the separate and combined jealousies of the long-established bureaus, and still more the initial lack of training and experience in the first officers detailed to the new general staff reduced the latter almost to complete uselessness and impotence. Nevertheless, the traditional national distrust of anything savouring of a military oligarchy caused Congress in 1912 to decrease the number of general staff officers to 36. The National Defense Act raised this number to 57 to be reached, however, only in five annual increments, and with the proviso that not more than half of these officers should be "at any time stationed, or assigned to or employed upon any duty in or near the District of Columbia."

In connexion with the army legislation of 1916 Congress created also a Council of National Defense, to consist of the Secretaries of War, the Navy, the Interior, Agriculture, Commerce and Labor, with an advisory commission of 7 specially qualified citizens; and to this Council was committed the task of studying and coördinating the military, industrial and commercial resources of the nation in connexion with its defense.

The disorders in Mexico since 1911 had made almost continually necessary the patrolling of the long international boundary by the bulk of the regular army. In March 1916 a raid into U.S. territory by Villa had led to the calling-out of the National Guard and its concentration along the border, while an expeditionary force of regular troops under Gen. Pershing was sent into Mexico. In Feb. 1917 the expeditionary column was withdrawn and the National Guard organizations returned to their respective states. The close of this emergency, almost coincident with the entry of the United States into the World War, left the regular army with a large percentage of its men due for discharge because of expiration of their terms of enlistment and left the National Guard in the throes of a combined demobilization and reorganization.

1917 to 1919.—In March 1917 the actual strength of the regular army was 5,791 officers and 121,797 men, of the National Guard 3,199 officers and 76,713 men, a total of 207,500 officers and men. In addition there were 97,295 enlisted men of the National Guard who had not yet taken the oath of federalization. The General Staff Corps, though by this date composed of trained and competent officers, had a total strength of only 41 members, of whom, under the law, only 19 could be stationed in or near Washington. Soon after the declaration of war by the United States, April 6 1917, the evident and acknowledged military unpreparedness of the United States led to tentative suggestions from the Allied Powers that such forces as the United States had at its disposal be at least temporarily merged into the more experienced units of the Allied armies. But the Government in Washington considered that, in spite of popular enthusiasm, American sentiment would not tolerate any such absorption. Accordingly, the order appointing Gen. Pershing commander-in-chief of the American Expeditionary Force specifically charged him, while coöperating in all ways with the Allied military authorities, to "reserve the identity of the U.S. force." It was further thoroughly understood and agreed on by the U.S. authorities that the mission of the overseas force was to be an offensive one. These two conceptions, maintained throughout the war, governed all war plans and activities of the United States both at home and abroad.

It was immediately decided, as a tentative programme, (*a*) to send overseas promptly a small but complete body of American troops, in the form of one tactical division to serve as a nucleus for the organization and training of American overseas troops and in order that some American troops might be put into the trenches at the earliest possible moment, and (*b*) to follow this by an expedition-

ary force of sufficient size, if the shipping situation permitted, to make American military participation an effective factor in the prosecution of the war. Accordingly, on May 28 1917 Gen. Pershing, with a small staff, sailed for Europe and in June the 1st Div. regular army, 12,261 men, accompanied by 2,798 marines, was embarked.

Mobilization.—On May 18 1917 there was passed and approved the Congressional Act known as the Selective Service law. It provided that, in addition to the regular army and the National Guard, there be raised for the emergency a national army, by selective conscription of men between the ages of 21 and 30, of which army the President was empowered to summon two units of 500,000 men each at such time as he should deem wise. The same Act removed, for the period of the emergency only, all restrictions as to the numbers and location of officers of the general staff. On July 3 the President called into service the entire National Guard and 16 divisional camps were established for their concentration and training. The first registration under the Selective Service law, June 5 1917, was carried out in the main by the voluntary efforts of citizens and gave a total of 9,587,000 registrants. The actual drafting into service was delayed by the necessity of waiting for the construction of the 16 divisional cantonments planned for the national army, and by the lack of equipment and especially of woollen clothing. The first draft, Sept. 1917, inducted into military service 296,678 men, and up to Dec. 1 1917 there had been drafted from this first registration 496,043 men. On Dec. 15 voluntary enlistments of men between 21 and 30 were discontinued. From that date also all registrants were arranged in five classes according to their importance to the economic interests of the nation and the support of dependents. The men thus placed in Class I. were first rendered liable for military service, and in the sequel the four "deferred" classes were never called upon. In May 1918 Congress provided that the quotas of the various states should be apportioned according to the number of registrants in Class I. instead of according to population. The final total registered, including those coming of age during the operation of the scheme, was upwards of 10,481,000 men. Of these there had been, on Nov. 11 1918, inducted into military service by the draft 2,801,635, or about 25 per cent. In July 1918 it became evident that the then extended military programme would soon lead to the exhaustion of Class I. In order to prevent the industrial disturbance and economic hardships incidental to calls on the deferred classes, Congress provided for the registration of all males between the ages of 18 and 45, both inclusive, and made registrants liable to service in the navy and the Marine Corps as well as in the army. This registration, held Sept. 12 1918, yielded an additional total of 13,228,000 registrants, but owing to the close of the war these were never drawn upon. The following table shows, in round numbers, the recruiting from month to month:—

Month.	Drafted.	Voluntary Enlistments. All Ages.	Aggregate.
1917			
Sept.	297,000	24,000	321,000
Oct.	164,000	31,000	195,000
Nov.	36,000	46,000	82,000
Dec.	20,000	142,000	162,000
		Outside Draft Ages	
1918			
Jan.	23,000	41,000	64,000
Feb.	84,000	26,000	110,000
March	132,000	25,000	157,000
April	174,000	23,000	197,000
May	373,000	26,000	399,000
June	302,000	28,000	330,000
July	401,000	19,000	420,000
Aug.	283,000	11,000	294,000
Sept.	263,000	—	263,000
Oct.	107,000	—	107,000
Nov.	7,000	—	7,000

Replacements.—In April 1918 there were added to the 32 training-camps already functioning in the United States nine replacement camps of various arms. These were intended to supply the necessary replacements (British "drafts") for the overseas troops, calculated at from 10 % to 25 % a month, and to obviate the necessity of drawing upon divisions already organized and in training.

New Officers.—One of the most serious problems which confronted the War Department, in April 1917, was the securing of a sufficient number of officers. To meet this need a first series of 16 officers' training-camps was opened on May 15 1917. Officers previously commissioned in the Reserve Corps were required to attend and in addition some 30,000 selected voluntary candidates were admitted. In Aug. there were graduated from this first series 27,341 officers, a number sufficient to meet immediate needs. A second series was opened in Aug. 1917 and a third in Jan. 1918. The first two classes were essentially civilian in character and largely from the university element, and because of the need for officers of all grades commissions were granted up to the grade of colonel. The third class drew 90 % of its candidates from the enlisted ranks of the regular army and its graduates were commissioned as second lieutenants. These first three classes had supplied, to April 1918, a total of 57,307 new officers.

War Department Organization.—Gen. Pershing, who had been given the greatest latitude in the carrying-out of his mission, had very early established the general staff of the Expeditionary Force, selecting from the British and the French systems those features which seemed best adapted to the basic organization of the American army. But the War Department in Washington was in this matter dependent upon Congressional legislation. As the war progressed the system of separate and independent bureaus eventually and inevitably developed a condition of affairs which threatened to jeopardize the success of the military programme. Each bureau, absorbed in the sudden expansion of its personnel, and in its own problems of supply, concentrated its efforts on its own needs without reference in general to the requirements of other bureaus or services or of the army programme as a whole. It was not until May 20 1918 that a Congressional Act made it possible to provide for: (*a*) a redistribution of the functions of already existing bureaus; (*b*) the creation of certain new agencies and services made necessary as the result of the development and experiences of the army overseas; (*c*) the reorganization of the general staff into five main divisions in such a manner as to enable it to perform its proper functions of an effective central controlling agency.

The American Expeditionary Force.—The original tentative programme had contemplated in a general way the placing in France by the end of 1918 of approximately 1,000,000 men. Between July and Oct. 1917, after consultation with the Allies and a study by Gen. Pershing and his staff of Allied organizations, a more definite programme was drawn up. In order that the services of the rear might keep pace with the arrival of the combat troops this plan was divided into six phases and contemplated the placing in France by Dec. 31 1918 of 1,372,399 troops consisting of 30 divisions, organized into 5 corps of 6 divisions each (4 combat, one training, one replacement), with 2 regiments of cavalry, the necessary corps troops, army troops, service of supply troops, and replacements. It was decided that the American combat division should consist of 4 regiments of infantry (of 3,000 men each, with 3 battalions to a regiment and 4 companies of 250 men each to a battalion); one artillery brigade, of 3 regiments; one machine-gun battalion; one engineer regiment; one trench-mortar battery; one signal battalion; wagon trains; and the headquarters staffs and military police. These with the medical and other units for each division made a total of over 28,000 or practically double the size of the French or German division. With 4 divisions fully trained a corps could take over an American sector with 2 divisions in line and 2 in the reserve, with the depot and replacement divisions prepared to fill the gaps in the ranks.

In July 1918 an extension of the original programme was adopted contemplating, by July 30 1919, 80 divisions in France and 18 at home, based on a total strength of the American army of 4,850,000. A further extension, approved Sept. 3 1918, was communicated to the supply departments. It provided for an army of 4,260,000 (100 combat divisions) in France, with 1,290,000 (12 combat divisions) in the United States, a total of 5,550,000 to be reached by June 30 1920. Up to the signing of the Armistice the troops were being transported to France in accordance with the July 1918 programme. The needs of training in the overseas forces, and especially of first constructing the necessary facilities for the services of the rear for an independent American army, at first greatly delayed the entry into line of American troops. On Dec. 31 1917 there were in France only 176,665 American troops and but one division had appeared on the front. On Nov. 11 1918, 40 American divisions had reached France (7 regular army, 17 National Guard, 16 national army). At this date the American troops represented 31 % of the ration strength of the Allied forces in France and held 22 % of the length of the western front. Toward the later stages of the war 2 American divisions coöperated with the Australian corps; 2 divisions assisted the French IV. Corps; and 2 divisions fought with the French VI. Army in Belgium. During the Meuse-Argonne battle 29 combat divisions operated on the American front. Nov. 20 1918 Gen. Pershing, after estimating losses, reported in France 1,338,169 combatant troops. Of the 40 combat divisions which had arrived the infantry personnel of 10 had been used as replacement troops, leaving at that time in France 30 divisions organized into 3 armies of 3 corps each. Of these forces approximately 44 % had been transported overseas in American, 51 % in British, 3 % in Italian and 2 % in French ships.

Losses and Casualties.—To Nov. 18 1918 the losses were: killed in action, 35,556; died of battle wounds, 15,130; of other wounds, 5,669; of disease, 24,786; total deaths, 81,141; wounded, 179,625; missing, 1,160; prisoners, 2,163. Total casualties, 264,089. Of the wounded about half suffered very slight injuries.

Other Fronts.—In addition to its military effort in Europe the United States remained throughout the war under the necessity of maintaining its patrol organizations along the Mexican border. The bulk of its cavalry with some artillery was thus employed. In Sept. 1918 an expeditionary force of 10,000 was sent to Siberia in coöperation with other Allied troops. A small force of 5,000 men sent with the Allied expedition to Murmansk formed part of the A.E.F. organization. One U.S. regiment served in Italy.

Growth in strength and variety of services between March 1917 and Nov. 1918 (in round numbers.)

Service.	Old Army March 1917.	New Army Nov. 1918.
Infantry	85,000	974,000
Engineer	3,000	394,000
Field Artillery and Ammunition Train	9,000	389,000
Medical	7,000	300,000
Quartermaster	8,000	228,000
Coast Artillery	21,000	137,000
Ordnance	1,000	64,000
Signal	3,000	52,000
Cavalry	22,000	29,000
Air	none	202,000
Motor Transport	"	103,000
Militia Bureau	"	27,000
Chemical Warfare	"	18,000
Tank	"	14,000
In Training	"	549,000
All Other	31,000	185,000
	190,000	3,665,000

Demobilization.—The problem of demobilizing was simpler for the United States than for other countries. Pivotal or key men had not been withdrawn from industry nor had the man-power been drafted to the same extent. Moreover, since all units contained a fair proportion of men from all trades and commercial activities, it had already been decided to demobilize by complete units as they could be spared. A few priority exceptions were made in the case of coal-miners, railroad men, certain post-office employees, etc. Demobilization of emergency units still in the United States began immediately. The chief difficulties were met in the regular army, where only a few thousand men were still serving under enlistment contracts entered into prior to 1917, and in the National Guard, where recruits and replacements had infiltrated every organization with drafted men. As under these conditions rapid demobilization would have meant the disbanding of practically all organized military forces in the United States, authority was granted by Congress, in Feb. 1919, to reopen voluntary enlistments for the regular army and National Guard. To insure the return of all men as speedily as possible to their former places in the economic life of the nation, the general plan provided for the transportation of each man, previous to discharge, to the demobilization camp in or nearest to the state from which he had entered the service. For this purpose 31 former training-camps were utilized. On arrival in the United States, unless sick or wounded, the men were immediately distributed to their proper discharge camps. There each soldier, after a final physical examination and other routine processes, was discharged, paid and entrained for his home or place of entry. Men sick or still suffering from wounds or infectious diseases were not discharged until cured or otherwise provided for. The initial lack of American tonnage delayed for a time the return and discharge of the overseas troops, but between Nov. 11 1918 and June 30 1919 there were returned from France 1,610,074 men and officers, of which number 84 % were transported in American ships. The record for the month of June was 434,786 men, the greatest number shipped across in any one month. In Nov. 1919 there had been discharged, in all, 179,800 officers and 3,236,266 men. The discharge of men in the ranks was practically completed on April 1 1920. (A. L. C.)

VII.—Balkan Armies

(1) *Serbia.*—In 1911 the Serbian army consisted of 5 infantry divisions each of 4 regiments, one cavalry division, and special formations of mountain and siege artillery. The army thus comprised 20 infantry regiments of 3 battalions each, 4 cavalry regiments of 4 squadrons, 7 f.a. regiments (45 batteries f.a., 2 batteries horse artillery, 9 mountain and 6 how.), 2 battalions of siege artillery, 2½ battalions engineers, a cavalry telegraph section. The *peace strength* of the army was 2,033 officers, 4,338 under-officers, 22,559 men. From 1901 the Serbian army was raised on the compulsory system, by which all able-bodied Serbs became liable for military service on attaining 21 years, and remained so till the completion of their 46th year. The first two years were supposed to be spent with the colours, though in practice this was reduced to one and a half, after which the soldier passed to the 1st line reserve for nine years. He then passed to the 2nd line reserve for six years, and to the 3rd line for the remainder of his period of liability. The yearly quota of recruits was during the years immediately preceding 1910 about 25,000.

The infantry was equipped with a 7-mm. Mauser with a range of 2,000 metres. Each man carried 150 rounds on his person. The artillery before the outbreak of the Balkan War was in process of being equipped with the modern French field gun (75-mm. field and 70-mm. mountain guns). The older weapons which were being replaced were the 85-mm. de Bange. There were no field howitzers, but there was a siege train with 12- and 15-cm. howitzers.

The *war strength* of the mobilized field army thus comprised 5 active infantry divisions, 5 divisions 2nd line reserve, 5 divisions 3rd line reserve, one Ersatz division of 1st line reservists approximating in composition to an active division. In addition the commander-in-chief had for his own disposal one cavalry division, one guard detachment (2 squadrons), one heavy field-artillery regiment, one siege-artillery regiment, some railway and balloon troops. The total mobilized strength, representing the maximum effort of the country, was about 260,000 men.

As a result of the Balkan War the 5 divisions of the standing army were increased by another 5 (the Kosovo, Vardar, Monastir, Shtip, and Ibar divisions), all formed from the new territory acquired. The artillery was also increased by 10 batteries. Owing, however, to the very short time of peace which elapsed between the close of the 2nd Balkan War (July 1913) and the outbreak of the World War, the reorganization which had been contemplated could only be carried out in part.

On being mobilized at the end of July 1914, when Austria-Hungary declared war, the Serbian army totalled about 350,000 men, and it was organized, now for the first time, in four armies of three divisions each.

(2) *Bulgaria.*—In 1911 the Bulgarian army was organized in 9 infantry divisions of 4 regiments (formed into 3 army inspectorates which on mobilization formed 3 armies), and 11 cavalry regiments. The army thus comprised, on a peace footing, 36 infantry regiments (each consisting of 2 battalions, one non-combatant company, and one machine-gun section), 11 cavalry regiments (each of 3 squadrons), 9 field-artillery regiments (each of 6 batteries), 3 mountain-artillery regiments (each of 4 batteries), 3 field-howitzer batteries, 3 siege-artillery groups, 3 pioneer battalions, a telegraph, pontoon, and railway battalion, one mechanical transport company, one cyclist company, one balloon company, 3 army service corps detachments, 16 frontier companies. The total strength of the army was 3,891 officers and 55,709 men. The army was raised on the compulsory service system. Every Bulgarian was liable to military service from his 20th to his 46th year. The classes were called up annually and a man normally served two years in the active army (or three in the case of the special arms), and then passed to the reserve until the completion of his 46th year.

The infantry were armed with the 8-mm. Mannlicher with a range of 2,100 metres. A few Russian Berdan rifles were to be found. Each man carried 150 rounds on his person. The cavalry had Mannlicher carbines; only the guard cavalry had lances. The artillery was mostly of French pattern: the 75-mm. Schneider-Creuzot field gun, 10·5-cm. field howitzer (Schneider-Creuzot), and 75-mm. Schneider mountain gun, with a few 12-cm. and 15-cm. Krupp and Creuzot howitzers.

On mobilization each of the 9 peace infantry divisions split into 2. Each of the 4 companies of the 72 infantry battalions expanded into a battalion. The 11 cavalry regiments, reënforced by mounted police, formed one cavalry division of 6 regiments, and the (infantry) divisional cavalry. An infantry division on a war footing thus consisted of 4 regiments of 4 battalions each; 2–4 machine-gun companies; 10 batteries of 4 or 6 guns; 2 squadrons cavalry; one howitzer battery; 2 engineer companies. The mobilized strength of the field army was about 350,000 men. In addition 72 battalions of older men (500 strong) were formed for garrison and L. of C. duties. There were thus about 400,000 men under arms.

After the Balkan War the permanent strength of the Bulgarian army was slightly increased, proportionately to the increment of population. A 10th division—the Aegean or White Sea Div.—was raised, and the army on a peace footing numbered 85,000 men.

In Sept. 1915, 10 divisions of 24,000 men each were mobilized according to plan, but as the World War progressed other formations were added. In 1916 an 11th Macedonian division was raised, mainly of Macedonians in the conquered territory of Serbia. Later a 12th division was raised, and towards the end of the war there were 14 divisions in the field. The system of splitting peace divisions into two, which had been followed in the Balkan War, had been dropped, but a division formed 6 regiments, instead of 4. A Bulgarian division of full strength was thus 24 battalions—24,000 rifles and 2 regiments of artillery. An order of battle published by the Bulgarian general staff on Sept. 15 1918—two weeks before the Armistice—shows a grand total of 877,000 men of all ranks under arms.

(3) *Greece.*—In 1911 an Act was passed which provided for the reorganization of the Greek army. This reorganization contemplated 3 large divisions of infantry (27 battalions each), corresponding much more to army corps than divisions, a cavalry division, a heavy artillery regiment, and technical troops. At the outbreak of the Balkan War in 1912 the total number of units which took the field was: 44 battalions of infantry, 16 cavalry squadrons, 47 batteries of field and mountain artillery. These were organized into 4 (active) divisions, each consisting of: 3 regiments (of 3 battalions, and 3 machine-gun companies each), 2 battalions of evzones (rifles), one cavalry squadron, 9 batteries field artillery or mountain artillery, 2 companies pioneers. The remaining cavalry was formed into a cavalry division. In addition to these 4 active divisions there were also 3 or 4 reserve divisions, similarly constituted. The army thus mobilized had a combatant strength of about 120,000 and a ration

strength of about 185,000. The total number of men with the colours at the end of the war was 210,000.

The infantry were armed with the Mannlicher-Schonauer rifle 6·5 mm., or the French 11-mm. Gras rifle. The cavalry had lances, and carbines of the same pattern as the infantry rifle. The field and mountain artillery were armed with the 75-mm. Schneider-Creusot, though some of the mountain batteries had the 7·5-mm. Schneider-Danglis (" screw-gun "). The heavy artillery was all of old pattern.

At the conclusion of the Balkan War a thorough reorganization of the army was undertaken. By the end of 1914 the army was, on paper, organized into 5 army corps of 3 divisions each, an independent cavalry brigade of 2 regiments, and a regiment of fortress artillery and fortress engineers. A Greek corps thus consisted of the following: 3 infantry divisions (of 3 regiments and one group of mountain artillery), one cavalry regiment, one field-artillery regiment, one regiment engineers, medical and intendance units. The total strength of a corps was about 30,000 combatants. The artillery organization was somewhat peculiar. Infantry divisions were provided with only 3 batteries of mountain artillery, field artillery being retained as corps troops. There was practically no heavy field or siege artillery. On Bulgaria joining the Central Powers in Sept. 1915 the Greek army was mobilized as a precautionary measure. The total strength mobilized was about 150,000 combatants. When in June 1917 Greece joined the Allies, 3 divisions (about 20,000 rifles) were already in being at Salonika, and it was expected that 10 divisions would finally be raised to take part in operations on the Salonika front. By the Armistice there were actually (in Macedonia) 9 divisions (3 corps) of about 60,000 combatants in line. They had been practically entirely armed and equipped by the Allies at Salonika. They participated and gave a good account of themselves in the final offensive against Bulgaria in Sept. 1918.

(4) *Rumania.*—Under the Army law of 1908, amended in 1910, military service was universal, and lasted from the completion of the 21st to that of the 42nd year, 7 years being spent with the colours, 10 in the reserve, and 4 in the militia.

In May 1913 a new recruiting law increased the total length of service to 25 years—from the 21st to the 46th year of age. The new term included 7 years with the colours, 12 years with the reserve, and 6 years with the militia. In 1913, out of a pop. of seven and a half millions, Rumania took 0·66% as recruits, and the peace establishment of the army amounted to 1·17%, without counting officers or administrative staffs. It was intended to increase the number of recruits to 52,000 in 1914. The peace strength of the army in 1913 showed 5,029 officers, 979 officials, 5,476 reëngaged non-commissioned officers, 85,791 men. In connexion with the new recruiting law, it was also decided in May 1913 that the " army of operations " should consist of the active army (1st line) and the reserve (2nd line) while the militia (3rd line) was designed for employment in the interior of the country, as well as in rear of the army of operations. In 1913, before the mobilization against Bulgaria, the infantry consisted of 40 regiments, of which 32 had 3 and 8 had 2 field battalions to one Ersatz battalion. To each regiment there were one machine-gun section with 3 guns; 9 Jäger battalions, each with one machine-gun section of 2 guns; 12 frontier guard companies; 2 gendarmerie companies; 80 reserve battalion cadres. In 1913 these would form, for war purposes as first-line troops: 40 infantry regiments of 3 battalions, 18 Jäger battalions, 12 frontier guard companies. The second-line troops would comprise 40 reserve infantry regiments of 2 battalions, and the third line 40 militia battalions. In war-time one machine-gun section (2 guns) would be formed for each first-line battalion. The armament of the line and reserve troops consisted of Mannlicher repeating rifles, mark 93, calibre 6·5 mm. The field artillery was being extensively developed up to the summer of 1913. By the summer of 1913 the artillery establishment had reached the following numbers: 10 artillery brigade commandos; 20 field-artillery regiments, each of 6 field batteries and one Ersatz battery; 5 field-howitzer detachments of 3 field batteries and one Ersatz battery; one mounted artillery detachment of 2 batteries; one heavy howitzer detachment of 2 batteries; one mountain-artillery regiment of 4 batteries. In war-time 4 reserve field-artillery divisions of 3 foot batteries were to be formed for the reserve divisions of the infantry. The artillery armament included 7·5-cm. Krupp quick-firing guns, mark 1904 for foot, mark 1908 for mounted batteries; 12-cm. Krupp light field howitzers, afterwards gradually replaced by 10·5-cm. field howitzers, and 6·3-cm. Armstrong mountain guns. For heavy (fortress) artillery in 1910 there were two regiments, each of 2 battalions of 8 and 11 companies respectively. By 1913 this arm had been increased by 3 companies.

In 1913, when Rumania mobilized in case of intervention becoming necessary against Bulgaria, the war muster of the field army included 8,500 officers and 373,500 men. There were, in addition, 45,000 men of the territorial commandos in the interior of the country, and about 55,000 men not embodied. The total number called up was thus about 473,000 men.

In Aug. 1914 Rumania, in view of the political situation, successively called up all the men of the previous seven-year classes. In Oct., however, the Government decided for armed neutrality, and the army reverted to a peace footing. The strengthening of the army proceeded nevertheless at an increasing rate up to the time of Rumania's entry into the war. At the end of Aug. 1916 the total war strength of the Rumanian army included 330–340 battalions of first- and second-line infantry, 80 battalions of third-line infantry, and 112 squadrons of cavalry, while the artillery of the field army included 768 modern guns. The total number of trained men available when Rumania entered the war in 1916 was about 860,000. Of these 700,000 men were taken for the field army, so that there remained for use as Ersatz troops 160,000 trained men in addition to about 150,000 not yet trained.

On Aug. 27, when Rumania declared war on Austria-Hungary, the mobilization and marching forward of the army had proceeded so far that the advance against Siebenbürgen immediately followed the declaration of war. Rumania put four armies in the field, one operating in the Dobrudja and three against Siebenbürgen. The field troops were formed into 23 infantry and 2 cavalry divisions. After the decisive defeat in Dec. 1916 the reconstruction of the army was seen to be a pressing necessity, and this was effected under a French military mission. The work of reorganization carried out by the French mission had excellent results. From July 1917 onwards the I. Army was again at the front. In the battles fought between the end of July and the middle of Sept. 1917, the army possessed an actually greater battle strength than when it entered the war.

VIII.—The German Army

In the four years up to the outbreak of the World War, intensified progress was made in the German army along normal lines, but in Aug. 1914 there began and continued an astounding military effort which in many ways differed from that which the peace-time system had led observers to expect. To attempt to understand that effort, therefore, one must return to fundamentals. General Ludendorff, in his *War Memories*, in saying that each of the various component states produced good divisions and poor divisions, adds—" Württemberg and Baden had only good ones." In this judgment the Entente intelligence staffs, whose specialty was study of the opponent's quality, would concur. Yet in 1870 these two contingents had a very small share in victory, and in earlier times their troops, though figuring in many wars as components of this or that federal army, never won for themselves an outstanding reputation for high quality. On the contrary, these countries were the very home of the old German *Gemütlichkeit*, and in the 18th century Burke quoted Württemberg as a model of a peacefully and constitutionally governed country.

In reality, two cultural waves, so to say, contributed to make the German army what it was: first, the tide of Germanic civilization which spread from the upper Rhine and Danube countries N.E. over the mountains and into the great plain of the Slavs, and secondly, the tide of Prussian " objectivity " and efficiency which in the 19th century set in in the reverse direction, from N.E. to S.W. And it can be said without forcing the facts, that the military quality of Germany was fundamentally soundest at those two moments in history when, in 1813, the sense of civilization and nationality worked for the first time strongly upon the hard " East-Elbians," and when in 1914–5 the spirit of business and duty imposed by these East-Elbians upon the peaceful S.W. made their inborn nationalism an effective instead of an ineffective thing.

The study of these currents is, of course, practically the same as the study of German history. But one thing may here be emphasized. No other basic hypothesis than that of continuing national characters can account for the fact that these two comfortable S. German states were awarded primacy in military quality by a Prussian commander-in-chief. Were it otherwise, the quality of the various contingents would simply have been measured by the length of the period during which their respective states had been subjected to the civil and military training of Prussia. Such a criterion has in fact been applied, but it proved false even in respect of the active army of peace-time. Nevertheless, as Prussian military ideas and methods provided the skeleton on which this spirit was made flesh, and which fortified the flesh against weakness, an objective account of the German army of the war period must begin with a schematic presentation of that skeleton.

Higher Formations in Peace.—The growth of the Prussian-German military organization from 1815 to 1914 is shown by the accompanying Table A (The Roman numerals indicate the corps to which a division belonged at the time considered. When

the corps numeral is in brackets, the division is attached to that corps as a third division.)

It must be premised that the corps numbers indicate territorial districts as well as military commands. The six "Brigade" districts of Prussia during the period of army limitation imposed by Napoleon became corps districts after 1815, and two others were added when for the first time Prussia acquired Rhine possessions adjacent to France. The annexations of 1866 produced three other Prussian corps and corps districts, and thereafter the course of evolution is sufficiently indicated in the table. After 1871, of course, all new districts were carved out of the existing ones. It will be seen from Table A that during the organization of 1912 there had been bitter controversy—the general staff demanding five new army corps and the Reichstag conceding only two—and no fewer than 17 supernumerary regiments (more than the infantry complement of two army corps) were left ungrouped after the 20th and 21st Corps had been formed. These 17 were a fifth brigade and an eleventh regiment in the Guard, fifth brigades in the frontier corps regions 5th, 6th, 7th, 9th, 14th, and ninth regiments in the 2nd, 13th, 18th and 21st Corps.

There were, therefore, in the active army of 1914, 50 divisions (two Guard, 1–42, and 1–6 Bavarian) and 17 supernumerary infantry regiments.

N.B.—Two Bavarian army corps (4 divs.), one Württemberg and one Baden division took part in the war of 1870–1 as allies of the N. German Confederation.

Empire period the typical form of growth had been the creation of third divisions in certain corps (usually frontier corps) and which from time to time coalesced in corps possessing districts of their own. These third divisions themselves were the product of a gradual growth. Resources in men, and from time to time the favour of the Reichstag, allowed the formation, now here now there, of regiments and brigades supernumerary to the standard corps establishment (2 divs. = 4 bdes. = 8 regts.). In each of the greater reorganizations these supernumeraries had been swept together to form new divisions. But over the last re-

Units in Peace.—Each of the 217 infantry regiments had an establishment of three battalions and a machine-gun company of six guns. The field artillery consisted of a brigade of two regiments (in all 12 batteries) per division, one quarter of these batteries being of field howitzers.[1] There were therefore 600 batteries in all. The cavalry, with its recent additions and groupings, numbered 110 regiments, of which 66 were in war to form 11 cavalry divisions with 33 batteries of horse artillery and 11 cavalry machine-gun detach-

[1] These establishments were, in many cases, hurriedly brought in force at the last moment; the law of 1913 had authorized the necessary recruiting and equipment but had spread it over a term of years.

strength of about 185,000. The total number of men with the colours at the end of the war was 210,000.

The infantry were armed with the Mannlicher-Schonauer rifle 6·5 mm., or the French 11-mm. Gras rifle. The cavalry had lances, and carbines of the same pattern as the infantry rifle. The field and mountain artillery were armed with the 75-mm. Schneider-Creusot, though some of the mountain batteries had the 7·5-mm. Schneider-Danglis (" screw-gun "). The heavy artillery was all of old pattern.

At the conclusion of the Balkan War a thorough reorganization of the army was undertaken. By the end of 1914 the army was, on paper, organized into 5 army corps of 3 divisions each, an independent cavalry brigade of 2 regiments, and a regiment of fortress artillery and fortress engineers. A Greek corps thus consisted of the following: 3 infantry divisions (of 3 regiments and one group of mountain artillery), one cavalry regiment, one field-artillery regiment, one regiment engineers, medical and intendance units. The total strength of a corps was about 30,000 combatants. The artillery organization was somewhat peculiar. Infantry divisions were provided with only 3 batteries of mountain artillery, field artillery being retained as corps troops. There was practically no heavy field or siege artillery. On Bulgaria joining the Central Powers in Sept. 1915 the Greek army was mobilized as a precautionary measure. The total strength mobilized was about 150,000 combatants. When in June 1917 Greece joined the Allies, 3 divisions (about 20,000 rifles) were already in being at Salonika, and it was expected that 10 divisions would finally be raised to take part in operations on the Salonika front. By the Armistice there were actually (in Macedonia) 9 divisions (3 corps) of about 60,000 combatants in line. They had been practically entirely armed and equipped by the Allies at Salonika. They participated and gave a good account of themselves in the final offensive against Bulgaria in Sept. 1918.

(4) *Rumania.*—Under the Army law of 1908, amended in 1910, military service was universal, and lasted from the completion of the 21st to that of the 42nd year, 7 years being spent with the colours, 10 in the reserve, and 4 in the militia.

In May 1913 a new recruiting law increased the total length of service to 25 years—from the 21st to the 46th year of age. The new term included 7 years with the colours, 12 years with the reserve, and 6 years with the militia. In 1913, out of a pop. of seven and a half millions, Rumania took 0·66% as recruits, and the peace establishment of the army amounted to 1·17%, without counting officers or administrative staffs. It was intended to increase the number of recruits to 52,000 in 1914. The peace strength of the army in 1913 showed 5,029 officers, 979 officials, 5,476 reëngaged non-commissioned officers, 85,791 men. In connexion with the new recruiting law, it was also decided in May 1913 that the " army of operations " should consist of the active army (1st line) and the reserve (2nd line) while the militia (3rd line) was designed for employment in the interior of the country, as well as in rear of the army of operations. In 1913, before the mobilization against Bulgaria, the infantry consisted of 40 regiments, of which 32 had 3 and 8 had 2 field battalions to one Ersatz battalion. To each regiment there were one machine-gun section with 3 guns; 9 Jäger battalions, each with one machine-gun section of 2 guns; 12 frontier guard companies; 2 gendarmerie companies; 80 reserve battalion cadres. In 1913 these would form, for war purposes as first-line troops: 40 infantry regiments of 3 battalions, 18 Jäger battalions, 12 frontier guard companies. The second-line troops would comprise 40 reserve infantry regiments of 2 battalions, and the third line 40 militia battalions. In war-time one machine-gun section (2 guns) would be formed for each first-line battalion. The armament of the line and reserve troops consisted of Mannlicher repeating rifles, mark 93, calibre 6·5 mm. The field artillery was being extensively developed up to the summer of 1913. By the summer of 1913 the artillery establishment had reached the following numbers: 10 artillery brigade commandos; 20 field-artillery regiments, each of 6 field batteries and one Ersatz battery; 5 field-howitzer detachments of 3 field batteries and one Ersatz battery; one mounted artillery detachment of 2 batteries; one heavy howitzer detachment of 2 batteries; one mountain-artillery regiment of 4 batteries. In war-time 4 reserve field-artillery divisions of 3 foot batteries were to be formed for the reserve divisions of the infantry. The artillery armament included 7·5-cm. Krupp quick-firing guns, mark 1904 for foot, mark 1908 for mounted batteries; 12-cm. Krupp light field howitzers, afterwards gradually replaced by 10·5-cm. field howitzers, and 6·3-cm. Armstrong mountain guns. For heavy (fortress) artillery in 1910 there were two regiments, each of 2 battalions of 8 and 11 companies respectively. By 1913 this arm had been increased by 3 companies.

In 1913, when Rumania mobilized in case of intervention becoming necessary against Bulgaria, the war muster of the field army included 8,500 officers and 373,500 men. There were, in addition, 45,000 men of the territorial commandos in the interior of the country, and about 55,000 men not embodied. The total number called up was thus about 473,000 men.

In Aug. 1914 Rumania, in view of the political situation, successively called up all the men of the previous seven-year classes. In Oct., however, the Government decided for armed neutrality, and the army reverted to a peace footing. The strengthening of the army proceeded nevertheless at an increasing rate up to the time of Rumania's entry into the war. At the end of Aug. 1916 the total war strength of the Rumanian army included 330–340 battalions of first- and second-line infantry, 80 battalions of third-line infantry, and 112 squadrons of cavalry, while the artillery of the field army included 768 modern guns. The total number of trained men available when Rumania entered the war in 1916 was about 860,000. Of these 700,000 men were taken for the field army, so that there remained for use as Ersatz troops 160,000 trained men in addition to about 150,000 not yet trained.

On Aug. 27, when Rumania declared war on Austria-Hungary, the mobilization and marching forward of the army had proceeded so far that the advance against Siebenbürgen immediately followed the declaration of war. Rumania put four armies in the field, one operating in the Dobrudja and three against Siebenbürgen. The field troops were formed into 23 infantry and 2 cavalry divisions. After the decisive defeat in Dec. 1916 the reconstruction of the army was seen to be a pressing necessity, and this was effected under a French military mission. The work of reorganization carried out by the French mission had excellent results. From July 1917 onwards the I. Army was again at the front. In the battles fought between the end of July and the middle of Sept. 1917, the army possessed an actually greater battle strength than when it entered the war.

VIII.—The German Army

In the four years up to the outbreak of the World War, intensified progress was made in the German army along normal lines, but in Aug. 1914 there began and continued an astounding military effort which in many ways differed from that which the peace-time system had led observers to expect. To attempt to understand that effort, therefore, one must return to fundamentals. General Ludendorff, in his *War Memories*, in saying that each of the various component states produced good divisions and poor divisions, adds—" Württemberg and Baden had only good ones." In this judgment the Entente intelligence staffs, whose specialty was study of the opponent's quality, would concur. Yet in 1870 these two contingents had a very small share in victory, and in earlier times their troops, though figuring in many wars as components of this or that federal army, never won for themselves an outstanding reputation for high quality. On the contrary, these countries were the very home of the old German *Gemüllichkeit*, and in the 18th century Burke quoted Württemberg as a model of a peacefully and constitutionally governed country.

In reality, two cultural waves, so to say, contributed to make the German army what it was: first, the tide of Germanic civilization which spread from the upper Rhine and Danube countries N.E. over the mountains and into the great plain of the Slavs, and secondly, the tide of Prussian " objectivity " and efficiency which in the 19th century set in in the reverse direction, from N.E. to S.W. And it can be said without forcing the facts, that the military quality of Germany was fundamentally soundest at those two moments in history when, in 1813, the sense of civilization and nationality worked for the first time strongly upon the hard " East-Elbians," and when in 1914–5 the spirit of business and duty imposed by these East-Elbians upon the peaceful S.W. made their inborn nationalism an effective instead of an ineffective thing.

The study of these currents is, of course, practically the same as the study of German history. But one thing may here be emphasized. No other basic hypothesis than that of continuing national characters can account for the fact that these two comfortable S. German states were awarded primacy in military quality by a Prussian commander-in-chief. Were it otherwise, the quality of the various contingents would simply have been measured by the length of the period during which their respective states had been subjected to the civil and military training of Prussia. Such a criterion has in fact been applied, but it proved false even in respect of the active army of peace-time. Nevertheless, as Prussian military ideas and methods provided the skeleton on which this spirit was made flesh, and which fortified the flesh against weakness, an objective account of the German army of the war period must begin with a schematic presentation of that skeleton.

Higher Formations in Peace.—The growth of the Prussian-German military organization from 1815 to 1914 is shown by the accompanying Table A (The Roman numerals indicate the corps to which a division belonged at the time considered. When

calculation that men, equipment and officers were available, the professional soldier could not believe that the most rigidly soldierly army of the Continent would put such formations into the front line when there had hardly been time even to establish military routine, let alone to revive the habit of march and manœuvre in the men.

Yet so it was. Schlieffen's ideas of mass and force, though watered down by his successor Moltke, were translated into practice. Two months later, an even more surprising move was made in the same direction—the employment of troops 75% of whom were entirely untrained at the outset.

In Aug. 1914, the seven armies deployed in the W. included all the 25 active corps except the 1st, 17th and 20th, 10 out of 11 cavalry divisions (Gd., Bav., 2–9), and the following reserve corps:—Guard Res. Corps (3 Guard Divs. made up of supernumerary active units and 1st Gd. Res. Div.); 3rd Res. Corps (5th and 6th Res. Divs.), 4th Res. Corps (7th and 22nd Res. Divs.), 5th Res. Corps (9th and 10th Res. Divs.), 6th Res. Corps (11th and 12th Res. Divs.), 7th Res. Corps (13th and 14th Res. Divs.), 8th Res. Corps (15th and 16th Res. Divs.), 10th Res. Corps (19th Res. Div. of Corps area, and 2nd Gd. Res. Div. so-called[1]), 12th Res. Corps (23rd and 24th Res. Divs., from the two Saxon Corps regions), 14th Res. Corps (26th and 28th Res. Divs. from Württemberg and Baden), 18th Res. Corps (21st and 25th Res. Divs. from the two Hesse, Frankfort and Darmstadt Corps areas), and 1st Bav. Res. Corps (1st and 18th Res. Divs.). After guarding the N. German coast for some weeks the 9th Res. Corps followed these (17th and 18th Res. Divs.). In the W. also were the 33rd Res. Div. formed at Metz, and the 30th Res. Div. formed at Strassburg, and three momentarily independent Bavarian Res. Bdes.[2]

The VIII. Army in the E. consisted of the 1st, 17th and 20th active Corps, the 1st Cav. Div., the 1st Res. Corps (1st Res. Div. and 36th Res. Div.), the 3rd Res. Div. formed in the II. Corps district.

Thus, in the W., the theatre of the first great decision, 73½ battle divisions were gathered of which 29½ were reserve formations, and in the E. (E. Prussia) six active and three reserve divisions were left to meet the attack of the Russian Vilna and Warsaw armies.

The 17 supernumerary infantry regiments also mentioned were absorbed in these reserve formations (with one exception) and the Instructional Battalion (afterwards famous as the "Lehr Regiment") was expanded to provide the 12th active unit of the Guard. Otherwise these formations were created entirely at the moment of mobilization. Their organization was similar to those of the active army, but for want of guns they were provided only with six batteries per division and had no heavy artillery of their own. In some reserve regiments machine-gun companies did not exist. In sum, and allowing for the active units incorporated, one-third of the first battle forces were reserve (though certainly not improvised) formations.

There were, however, yet other formations not so prepared in advance which found themselves fighting before the end of August. On general mobilization, the reserve, Landwehr, Ersatz reserve and trained men of Landsturm II., up to 42 years of age, had been called out. Landsturm I.—the pool of untrained men of all ages—was left alone, but volunteers presented themselves in enormous numbers. There were thus far more men than the depots could accommodate, and the volunteers were for the moment only registered. Enough men remained in the trained categories and in the Ersatz reserve not only to fill the active and reserve, but create (*a*) Landwehr and (*b*) so-called Ersatz formations, as well as units of Landsturm for guarding railways and other sensitive points and for the sedentary garrisons of forts.

Landwehr.—Landwehr brigades were formed to carry out the secondary duties which, it had been supposed, would fall to reserve divisions. The Ersatz, and to some extent the reserve formations, having absorbed part of the resources of Landwehr I., these brigades were constituted with the remainder and principally with Landwehr II., that is, trained men up to the age of 38½. Each army corps district, according to the resources of the region and also according to its output of "Ersatz" formation,[3] produced two or three Landwehr brigades, nearly all with a proportion of artillery and cavalry and engineers attached. In all, 99 regiments and some other units, making 314 battalions in all, mobilized in early Aug. 1914. Of these, 30 brigades were assigned to the W. to follow the various armies or to constitute the garrisons of fortresses (Metz, Strassburg, upper Rhine defences). Nearly all the remainder (about 17 brigades and several regiments as well), in the E., formed fortress garrisons and frontier guards which were very quickly drawn into the battles—indeed one whole corps, the Landwehr Corps (3rd and 4th Landwehr Divs.), was constituted as a field formation at the outset, and others also were formed into divisions. In connexion with these brigades and their coming into line, it should be added that just as they had relieved field troops of the necessity of occupying territory and guarding communications, so in turn they were after a short time relieved by Landsturm battalions, formed all over the empire from what remained of Landwehr II. and from the trained men of Landsturm II. up to 42 years of age.

Ersatz.—The term "*ersatz*" (replacement or substitute) was confined in normal usage to the category of reservists who were simply registered, not (as a rule) trained, and kept at call to fill gaps in the active army. It was, further, the official designation of the depot battalions which were formed on mobilization to provide drafts for active reserve or Landwehr units on service. But the resources of Ersatz battalions at the moment of mobilization were such that, in addition to allocating drafts for the field units, it was possible to create new units on a large scale. The principle followed in the case of the infantry—which was applied to other arms with suitable modifications—was for the Ersatz battalion of each regimental district to form and equip two service companies. Thus each brigade district was able to produce a battalion (known as a brigade Ersatz battalion), and the sum of these "B.E.Bs." with analogous units of the other arms, appeared in the field in the last days of Aug. 1914 as "Ersatz Divisions" (Guard, 4th, 8th, 10th, 19th and Bavarian). These divisions had an irregular organization; they consisted of two to four mixed brigades, each brigade having four or five battalions, four batteries, a half squadron of cavalry and an engineer unit.[4] In addition, the Ersatz battalions of a few reserve and Landwehr regiments also constituted B.E.Bs., and those of the reserve were grouped in two mixed brigades (Res. Ersatz Bdes.).

The six divisions cited above all took part in the western campaign after the first few days of battle. They were provided wholly by the Ersatz battalions of the western and central corps regions. In the E. a different system was followed.

It has been mentioned that three active corps, one and a half reserve corps and about 17 Landwehr brigades had been assigned to the eastern theatre. But in the alarm created by the Russian advance on E. Prussia, an instant augmentation became necessary. The formation of "B.E.Bs." was not attempted in the I., XX. and XVII. regions and only partially and temporarily tried in the V. and VI. Instead, the Ersatz battalions themselves were mobilized, every man who could be equipped being sent into the field, and only the surplus remaining behind to form the nucleus of new draft-finding battalions. The German general staff, in this as in all other cases, took great risks in improvising formations in the east. Not only Landwehr and Ersatz battalions but the most diverse units of all categories were put together in provisional regiments, brigades and divisions, first as mobile fortress garrisons but soon as field troops.[5] It was no doubt considered that racial passion would give such forces a military value as against the Russians that would compensate for their deficiencies of training equipment. These miscellaneous eastern formations constituted the Thorn, Breslau, Graudenz, Posen and Königsberg "Reserves" or "Corps," of which the two last named were equivalent to two divisions each, the others to one each. The formation of the Silesian Landwehr Corps of two divisions has already been mentioned. Further, one so-called "reserve" division, the (original) 35th, was created from the readiest elements of the Thorn mobile garrison, and yet another division was thrown off before the Thorn reserve as such became fixed as a division. The five fortresses named in fact were so to say volcanoes from which in various pulsations regiments, brigades, and divisions were successively discharged.

By the end of Aug., therefore, the German forces in the field consisted of several categories—the active divisions of peacetime, the reserve divisions nearly equivalent to the active in

[1] Staff was guard, but not troops.

[2] Other formations called "Reserve" detailed later were so only in name.

[3] No Guard Landwehr infantry regiments were formed.

[4] Most Landwehr brigades were also constituted as mixed brigades—in their case two regiments with troops of other arms attached.

[5] As an example, Runge's regiment of Griepenkerl's detachment, Thorn Corps, which in the winter of 1914–5 seems to have consisted of half a mobile Ersatz battalion from the XVII. Corps region, half a mobile Ersatz battalion from the II. region, the mobile Ersatz battalions of the 101st and 107th Saxons and parts of three Landsturm battalions from Posen province and Alsace.

strength of about 185,000. The total number of men with the colours at the end of the war was 210,000.

The infantry were armed with the Mannlicher-Schonauer rifle 6·5 mm., or the French 11-mm. Gras rifle. The cavalry had lances, and carbines of the same pattern as the infantry rifle. The field and mountain artillery were armed with the 75-mm. Schneider-Creusot, though some of the mountain batteries had the 7·5-mm. Schneider-Danglis (" screw-gun "). The heavy artillery was all of old pattern.

At the conclusion of the Balkan War a thorough reorganization of the army was undertaken. By the end of 1914 the army was, on paper, organized into 5 army corps of 3 divisions each, an independent cavalry brigade of 2 regiments, and a regiment of fortress artillery and fortress engineers. A Greek corps thus consisted of the following: 3 infantry divisions (of 3 regiments and one group of mountain artillery), one cavalry regiment, one field-artillery regiment, one regiment engineers, medical and intendance units. The total strength of a corps was about 30,000 combatants. The artillery organization was somewhat peculiar. Infantry divisions were provided with only 3 batteries of mountain artillery, field artillery being retained as corps troops. There was practically no heavy field or siege artillery. On Bulgaria joining the Central Powers in Sept. 1915 the Greek army was mobilized as a precautionary measure. The total strength mobilized was about 150,000 combatants. When in June 1917 Greece joined the Allies, 3 divisions (about 20,000 rifles) were already in being at Salonika, and it was expected that 10 divisions would finally be raised to take part in operations on the Salonika front. By the Armistice there were actually (in Macedonia) 9 divisions (3 corps) of about 60,000 combatants in line. They had been practically entirely armed and equipped by the Allies at Salonika. They participated and gave a good account of themselves in the final offensive against Bulgaria in Sept. 1918.

(4) *Rumania.*—Under the Army law of 1908, amended in 1910, military service was universal, and lasted from the completion of the 21st to that of the 42nd year, 7 years being spent with the colours, 10 in the reserve, and 4 in the militia.

In May 1913 a new recruiting law increased the total length of service to 25 years—from the 21st to the 46th year of age. The new term included 7 years with the colours, 12 years with the reserve, and 6 years with the militia. In 1913, out of a pop. of seven and a half millions, Rumania took 0·66% as recruits, and the peace establishment of the army amounted to 1·17%, without counting officers or administrative staffs. It was intended to increase the number of recruits to 52,000 in 1914. The peace strength of the army in 1913 showed 5,029 officers, 979 officials, 5,476 reëngaged non-commissioned officers, 85,791 men. In connexion with the new recruiting law, it was also decided in May 1913 that the " army of operations " should consist of the active army (1st line) and the reserve (2nd line) while the militia (3rd line) was designed for employment in the interior of the country, as well as in rear of the army of operations. In 1913, before the mobilization against Bulgaria, the infantry consisted of 40 regiments, of which 32 had 3 and 8 had 2 field battalions to one Ersatz battalion. To each regiment there were one machine-gun section with 3 guns; 9 Jäger battalions, each with one machine-gun section of 2 guns; 12 frontier guard companies; 2 gendarmerie companies; 80 reserve battalion cadres. In 1913 these would form, for war purposes as first-line troops: 40 infantry regiments of 3 battalions, 18 Jäger battalions, 12 frontier guard companies. The second-line troops would comprise 40 reserve infantry regiments of 2 battalions, and the third line 40 militia battalions. In war-time one machine-gun section (2 guns) would be formed for each first-line battalion. The armament of the line and reserve troops consisted of Mannlicher repeating rifles, mark 93, calibre 6·5 mm. The field artillery was being extensively developed up to the summer of 1913. By the summer of 1913 the artillery establishment had reached the following numbers: 10 artillery brigade commandos; 20 field-artillery regiments, each of 6 field batteries and one Ersatz battery; 5 field-howitzer detachments of 3 field batteries and one Ersatz battery; one mounted artillery detachment of 2 batteries; one heavy howitzer detachment of 2 batteries; one mountain-artillery regiment of 4 batteries. In war-time 4 reserve field-artillery divisions of 3 foot batteries were to be formed for the reserve divisions of the infantry. The artillery armament included 7·5-cm. Krupp quick-firing guns, mark 1904 for foot, mark 1908 for mounted batteries; 12-cm. Krupp light field howitzers, afterwards gradually replaced by 10·5-cm. field howitzers, and 6·3-cm. Armstrong mountain guns. For heavy (fortress) artillery in 1910 there were two regiments, each of 2 battalions of 8 and 11 companies respectively. By 1913 this arm had been increased by 3 companies.

In 1913, when Rumania mobilized in case of intervention becoming necessary against Bulgaria, the war muster of the field army included 8,500 officers and 373,500 men. There were, in addition, 45,000 men of the territorial commandos in the interior of the country, and about 55,000 men not embodied. The total number called up was thus about 473,000 men.

In Aug. 1914 Rumania, in view of the political situation, successively called up all the men of the previous seven-year classes. In Oct., however, the Government decided for armed neutrality, and the army reverted to a peace footing. The strengthening of the army proceeded nevertheless at an increasing rate up to the time of Rumania's entry into the war. At the end of Aug. 1916 the total war strength of the Rumanian army included 330–340 battalions of first- and second-line infantry, 80 battalions of third-line infantry, and 112 squadrons of cavalry, while the artillery of the field army included 768 modern guns. The total number of trained men available when Rumania entered the war in 1916 was about 860,000. Of these 700,000 men were taken for the field army, so that there remained for use as Ersatz troops 160,000 trained men in addition to about 150,000 not yet trained.

On Aug. 27, when Rumania declared war on Austria-Hungary, the mobilization and marching forward of the army had proceeded so far that the advance against Siebenbürgen immediately followed the declaration of war. Rumania put four armies in the field, one operating in the Dobrudja and three against Siebenbürgen. The field troops were formed into 23 infantry and 2 cavalry divisions. After the decisive defeat in Dec. 1916 the reconstruction of the army was seen to be a pressing necessity, and this was effected under a French military mission. The work of reorganization carried out by the French mission had excellent results. From July 1917 onwards the I. Army was again at the front. In the battles fought between the end of July and the middle of Sept. 1917, the army possessed an actually greater battle strength than when it entered the war.

VIII.—The German Army

In the four years up to the outbreak of the World War, intensified progress was made in the German army along normal lines, but in Aug. 1914 there began and continued an astounding military effort which in many ways differed from that which the peace-time system had led observers to expect. To attempt to understand that effort, therefore, one must return to fundamentals. General Ludendorff, in his *War Memories*, in saying that each of the various component states produced good divisions and poor divisions, adds—" Württemberg and Baden had only good ones." In this judgment the Entente intelligence staffs, whose specialty was study of the opponent's quality, would concur. Yet in 1870 these two contingents had a very small share in victory, and in earlier times their troops, though figuring in many wars as components of this or that federal army, never won for themselves an outstanding reputation for high quality. On the contrary, these countries were the very home of the old German *Gemüllichkeit*, and in the 18th century Burke quoted Württemberg as a model of a peacefully and constitutionally governed country.

In reality, two cultural waves, so to say, contributed to make the German army what it was: first, the tide of Germanic civilization which spread from the upper Rhine and Danube countries N.E. over the mountains and into the great plain of the Slavs, and secondly, the tide of Prussian " objectivity " and efficiency which in the 19th century set in in the reverse direction, from N.E. to S.W. And it can be said without forcing the facts, that the military quality of Germany was fundamentally soundest at those two moments in history when, in 1813, the sense of civilization and nationality worked for the first time strongly upon the hard " East-Elbians," and when in 1914–5 the spirit of business and duty imposed by these East-Elbians upon the peaceful S.W. made their inborn nationalism an effective instead of an ineffective thing.

The study of these currents is, of course, practically the same as the study of German history. But one thing may here be emphasized. No other basic hypothesis than that of continuing national characters can account for the fact that these two comfortable S. German states were awarded primacy in military quality by a Prussian commander-in-chief. Were it otherwise, the quality of the various contingents would simply have been measured by the length of the period during which their respective states had been subjected to the civil and military training of Prussia. Such a criterion has in fact been applied, but it proved false even in respect of the active army of peace-time. Nevertheless, as Prussian military ideas and methods provided the skeleton on which this spirit was made flesh, and which fortified the flesh against weakness, an objective account of the German army of the war period must begin with a schematic presentation of that skeleton.

Higher Formations in Peace.—The growth of the Prussian-German military organization from 1815 to 1914 is shown by the accompanying Table A (The Roman numerals indicate the corps to which a division belonged at the time considered. When

and were not put into the field till the "winter battle of Masuria" in Feb. 1915.

These divisions (except the Bavarian) were constituted on a new organic basis—that of three infantry regiments under one brigade staff instead of four in two brigades, a form which, as will appear presently, came to be adopted throughout the whole army. In artillery strength they were however superior to all previous reserve formations. The original reserve divisions had only six 6-gun batteries, and the first new reserve divisions, hurriedly mobilized as they were, had nine 4-gun batteries. In these second new reserves, the number of batteries was increased to 12 (as in active formations, but with 4 guns in lieu of 6 per battery).

With the creation of these divisions expansion proper ceased. Until 1917 no further divisions were formed otherwise than by regrouping existing units, and the intake of recruits of successive classes was, with very few exceptions, used for maintenance only. The end of Jan. 1915, therefore, marks the close of the expansion period. At that date there were 147 infantry divisions, or equivalents of infantry divisions.

Regrouping had naturally as its object the better strategic and tactical utilization of these 147 divisions. The first step was to sort out the miscellaneous formations of Ersatz and Landwehr, especially in the east. Accordingly, the Posen, Thorn, etc., corps were recast, divorced from the fortresses from which they had already become separated, and constituted as the 83rd–89th Divisions. These were on the 4-regiment basis, and the regiments after reorganization took the numbers 320–354 and 372–381 save that Landwehr units comprised in these divisions retained their original designations.

The battalions of Ersatz on the W. front (the "B.E.Bs.") were regimented chiefly with numbers between 357 and 371. On both western and eastern fronts the Landwehr brigades still unattached were used to form divisions, bringing the number of this category up to 19 (1–5, 6th Bav., 7–18, 1st Bavarian.)

The next step was a more important one. It had become clear, first of all, that the army corps, as a working unit, was not supple enough, and as early as Sept. 1914 the practice had set in, both with the Germans and with the French, of regarding the corps headquarters as an organ for the tactical and administrative management of any two or more divisions which might be assigned to it. This led in sedentary warfare to the corps becoming an area or sector command, and in open warfare or for the handling of battle reserves as a headquarters told off to carry out a particular mission. In either case, the inferiority of the German numbers in both theatres of war enforced a better arrangement of the corps commander's forces than the 2 × 2 system gave. In the spring of 1915, therefore, two series of divisions, numbered 50–58 (even numbers), 101–107[1] and 111–123 (odd numbers), 4th Guard and 10th and 11th Bav., were formed by taking a regiment each, and also one-quarter of the divisional artillery, from 50 or more existing active or reserve divisions. Thenceforward practically half the divisions of the army were on the new basis.

One other formation of the spring of 1915 must be mentioned. This was the Alpenkorps, a division formed for high mountain work when it became evident that Italy would enter the war. This *corps d'élite* served in every theatre, not only in mountainous country, and at the last moment of the war was dispatched from France to attempt to stop the Allied advance in Serbia. It was exclusively Bavarian in composition.

During the spring and summer of 1915, to ensure against accidents, the effectives of units in 3-regiment divisions were considerably increased, company strengths of over 300 being frequent. Later, however, the precaution being seen to be unnecessary, some new divisions were formed out of this surplus; these were the 183, 185, 187 and 192, originally called flying (*i.e.* non-sector) "brigades," but from the outset practically equivalent to divisions of the new type.

Practically no further additions were made till the battle of the Somme and the intervention of Rumania created a new situation. The creation of the so-called 5th Ersatz Div. and the 25th and 47th Landwehr Divs. (all three mixed brigades reënforced to the status of new type divisions) hardly amounted to more than a change of name.

The total of divisions and "equivalents" (the latter always diminishing as formations were regularized) remained stationary at the figure of 172 from July 1915 to the end of May 1916. The ration strength of the army was on March 31 1915, 5,029,672, and on March 31 1916, 6,767,144; and the losses had been as follows:—(8 months up to) March 31 1915, 281,389 killed, 205,048 missing, 835,612 wounded, 13,402 died of disease, etc.; (12 months up to) March 31 1916, 376,054 killed, 121,040 missing, 807,475 wounded, 29,840 died of disease, etc. The "definitive" losses—dead, missing, wounded discharged as unfit—are difficult to establish; but if we take for wounded not returned to duty the figure of 20% (which is a high one), we arrive at a total of "definitive" losses of all kinds of about 1,780,000 for the whole period. To repair these losses, and to increase the ration strength by some 1,750,000 men as well, the intake of recruits necessary would be about 2,500,000. These recruits were (*a*) the *Kriegsfreiwilligen*, (*b*) the class 1914, called up somewhat after the normal date, (*c*) the class 1915 called up before the normal date, and (*d*) the class 1916 called up before the normal *year*.

As early as the autumn of 1915, in fact, Germany had been compelled to anticipate the conscription, to bring youths of 19 as well as those of 20 to muster, and to shorten the period of training to the minimum.

The general policy followed was to consider a class collectively as a means to be allotted to specific ends. Later in the war the practice was carried to the extent that even when called up, trained and ready, a class was under embargo and could not be sent into the front line until the chief-of-staff, in consultation with the Government, should issue an order removing the ban. What may be called routine losses and wastage were made good as a rule by returned sick and wounded or other experienced men rather than by recruits.

Early in 1915, partly in order to have a reserve at hand, and partly in order to ensure an intensive training under realistic conditions, the system of "Field Recruit Depots" was gradually introduced. When these had been established, men spent only half or less than half of the abbreviated training period allowed in the Ersatz battalion at home and the remainder in the Field Recruit Depot a few miles behind the front. Eventually there was one depot per division, with an establishment (in 1917) of 1,350, of whom 900 were recruits under training and the rest training staff and returned wounded waiting allocation. Further, as pools to meet losses which could not be covered by the depots of the divisions affected, large training centres were created at Beverloo (the peace training camp of the Belgian army) and at Warsaw. The training camps in Germany were of course utilized for home training, and in them from time to time new batches of divisions were created and assembled. The period spent by the soldier in training varied considerably: sometimes it was as little as one month in the Ersatz battalion and two or three weeks in the Field Recruit Depot or at Beverloo; in less critical times it might be four to five months in all.

Hitherto, it will be noticed, little or no call had been made on the 5,000,000 men composing the untrained half of the male population of military age. This was because the maintenance of the country's economic life was more necessary than ever as the blockade tightened its pressure. Nevertheless, a certain combing-out of agriculture and industries began in the winter of 1915–16. Further, a law was passed in 1916 for the reëxamination of men who had been rejected by the annual muster commissions as permanently unfit.

From the summer of 1916 the situation of the German army became very critical. The costly offensive of Verdun had been followed by the Allied offensive on the Somme, the Russian break-through at Lutsk, the sixth Isonzo battle, and immediately thereafter Rumania's declaration of war. For the first time since 1914 the Central Powers were face to face with a simultaneous and prolonged strain on all fronts.

Before describing the measures taken to deal with this crisis, it is convenient to review the changes which had taken place in the meantime in the constitution of the fighting units themselves.

[1] The 108 and 109 were improvised during the eastern offensive of spring 1915.

The new type divisional organization has already been set forth, but within the infantry regiment itself there had been important changes, and there had grown up, besides, a great force of non-divisional troops, which were in some cases a pool from which allocations were temporarily made to armies as required, and in others were sector troops permanently allotted to particular parts of the front irrespective of the divisions occupying them. By now, the process of moving divisions into line and out to rest had become thoroughly established, though Verdun was the first battle in which the relief process was reduced to an almost mechanical system.

The changes may best be dealt with by arms.

Artillery.—It has been noted above that in the great reorganization of the spring of 1915 the field artillery had been recast on the basis of the 4-gun battery. The number of batteries therefore shows a large increase in that year, corresponding to the creation of new divisions. But in the main, the number of field guns and howitzers remained at the same level as in the spring of 1915. It was in the heavy and medium artillery (these were not differentiated in Germany) that expansion, as distinct from regrouping, occurred. The fortress guns were made mobile by various methods and old field guns of 9 cm. were brought out and emplaced as position guns on the less important parts of the front, pending the production of modern weapons; and in these and other ways the number of batteries of "foot artillery" actually in the field was increased from about 150 in Aug. 1914 to about 1,100 by the autumn of 1915 and 1,200 by the summer of 1916. The batteries received various descriptions, which need not be given here; substantially, they were grouped as required under "battalion" staffs, and when actually in line were under control of the divisional artillery command of the sector. Thus was initiated a principle of organization which presently became general in the belligerent armies and was applied to field artillery also—that of dividing the artillery into a portion which belonged organically to divisions and moved in and out of line with them, and a portion which was under higher control; this portion was partly emplaced in the various sectors as a normal allocation, partly kept in reserve to bring up the normal artillery strength of this or that sector to battle standard, as required.

Machine-guns.—Probably no legend of the war period obtained a wider circulation or was averred with more authority than the assertion that Germany put into the field in 1914 an enormously superior force of machine-guns. The facts, however, were known throughout to the Allied intelligence staffs, and are, as regards 1914-5, in no way extraordinary.

At the outset, Germany had only just completed the equipment of the active infantry with two guns per 1,000 rifles—the same scale as that of the British and French and Russian armies. The only difference was that they were employed in batteries, regimentally, instead of by sections battalion-wise as on the side of the Entente, and this no doubt produced a battle-field impression of inferiority on the British and French side since where German guns were used at all, they were used in mass. There were further some 16 (on mobilization 32) fortress machine-gun detachments, and 11 horsed machine-gun detachments allotted to the 11 cavalry divisions.

On mobilization, the majority of the reserve regiments were also provided with machine-gun companies, but for the armament of the remainder and of Ersatz and Landwehr units the fortress machine-gun detachments were called into the field at once. The first and second new reserves were sent into the field with one section of two guns per regiment. From all sources, the total of machine-guns in service at the end of 1914 was not more than 2,000, as against a peace establishment of 1,600.

But the Germans were the first to recognize the predominant rôle of the machine-gun in trench warfare. Manufacture was started on a scale then considered adequate, and during 1915 there were large additions. The regimental companies, where missing, were created, and further a number of "field sections" or "supplementary sections" were formed and attached to regiments as required. Thus by the end of 1915 every regiment had, either in organic companies or in attached sections, a force of 9 to 12 guns, though it was not until after the middle of 1916 that the latter figure was reached universally.

Meantime, a new type of machine-gun organization had come into existence, the "M.G. Sharpshooter Troops," each troop having six guns. These were selected from the "sections" of 1915, specially trained, grouped in permanent "detachments" (*Abteilungen*) and attached to divisions as required for battle. Their début was at Verdun in March 1916. By that date the number of guns in service had increased to about 8,000, and by the end of 1916 this figure was doubled.

At the period here considered, the light machine-gun, afterwards the primary armament of all German infantry, had hardly come into existence. Experiments had been made in the battle of Champagne (Sept.-Oct. 1915) and elsewhere with units armed with the Madsen gun and styled "*Musketenbataillone,*" but the results were not promising. The success of the French *fusil mitrailleur* and the British Lewis gun, however, made action imperative, and towards the end of 1915, to save the time which would have been lost in trying out and manufacturing a new model, the service heavy machine-gun was lightened sufficiently for use as an infantry weapon. This was not issued on a large scale till the end of 1916.

Trench Mortars (*Minenwerfer*).—At the outset of the war, the trench mortar (adopted as the result of the siege of Port Arthur) was a close combat weapon of siege warfare handled by sappers; in this rôle it figured at the sieges of Liége and Antwerp, where its bombs were highly effective. It was, however, the needs of trench warfare which brought it prominently to the front. As in other armies, the infantry felt the want of some short-range weapon which would enable them by curved fire to destroy and to harass the opposite trenches, and the creation of trench-mortar units soon followed. The Germans had here a real advantage in that they already possessed experience of the design and manufacture of these weapons, and for a considerable period they had the upper hand in this respect. The standard organization was by sections of heavy, medium, and light Minenwerfer which belonged to the pioneer arm, which were permanently assigned to divisions and were allotted within the division as required. Other Minenwerfer units were grouped in battalions and constituted a G.H.Q. reserve. Later the light Minenwerfer sections were permanently assigned to regiments, the others continuing as divisional troops.

Infantry organization as such remained unaltered, though the establishment was reduced in 1916, in order to meet the demands for men which were created by machine-gun and Minenwerfer expansion. At the same time a process began which in the long run proved injurious to quality but for the moment justified itself, the formation of "*Assault*" or "*Storm*" *battalions.* These were created, in anticipation of the Verdun offensive, in the winter of 1915-6, and were so successful that presently all infantry regiments and even battalions and companies raised their own assault detachments or squads. In the assault battalions proper, all trench warfare means were combined within the unit infantry guns, trench mortars, machine-guns and light flamethrowers. The separation of this élite from the bulk of the infantry was recognized by privileges and distinctions of dress. The net result, however, was to deprive the infantry of a leaven of first-class men, who in 1918 could no longer be spared from the ranks of their units. Towards the close of the war, therefore, the assault battalions were broken up one by one, and all assault units came to be regarded as schools of offensive tactics rather than as battle units.

Cavalry.—Little change had occurred in the cavalry between 1914 and 1916. Divisional cavalry was gradually reduced. All the cavalry divisions which had figured in the campaign of the Marne were sent E. by 1915, and there they played a conspicuous part in the operations both mounted and in the trenches. At the period now being considered (middle of 1916) they were still true mounted forces, though employed in the line like others. Cavalry regiments were each provided with a machine-gun squadron in 1915.

Pioneers.—Besides the Minenwerfer and chemical-warfare troops which had come into existence, other special services had been added to the pioneers, notably a large number of searchlight sections. Survey and sound-ranging units formed part of the artillery and not, as in the British service, of the engineers. The proportion of the pioneers themselves (British "field companies R.E.") was also augmented, and much use was made in 1915 of semi-permanent "Infantry Pioneer Companies" which were in reality infantry working parties detailed for particular pieces of constructional work, and retained as units till these were completed. From 1916, a large number of new Landsturm battalions were formed, as labour battalions.

The possibility of Rumanian intervention had been foreseen for some time, and in preparation for it four new divisions had been created by regroupings in the eastern theatre. These were the 195th, 197th, 199th and 200th; all these were principally composed of Jäger battalions assembled in regiments, and the last named, like the Alpenkorps, was specialized for mountain work. A little later the 91st, 92nd, 93rd Divs. were formed in Poland for quiet parts of the front. Several mixed Landwehr brigades were also expanded into Landwehr divisions for the same service. At the same time the 1917 class was called up gradually (May-Aug. 1916) for training, 15 months before the normal time, and the product of the March comb-out of industry was brought under training at the same time.

These measures, however, were not sufficient. To meet the pressure on all fronts not only men were needed, but, still more, increased flexibility of manœuvre, and it became essential, therefore, to create new battle-worthy divisions. These were obtained partly by regrouping, and partly—in the early months of 1917—by creating another batch of wholly new divisions.

During the crisis itself, which extended from July 1 to Dec., and then, with a brief respite, from Feb. to May 1917, it was

impossible to carry out regrouping with the smooth regularity of March 1915; the measures taken, therefore, extend over the whole period. They were as follows: (*a*) The constitution of new divisions (201–204 and 12th Bav.) out of odd units existing in various theatres and of "combings" obtained in the lines of communication, the Ersatz battalions and other military establishments in Germany. The infantry regiments of these divisions were numbered 401–416 and 26–28 Bavarian. (*b*) The regrouping of all old divisions still remaining on the 4-regiment basis as 3-regiment formations of the new standard type—*i.e.* the completion of the process which had been half carried out in March 1915. This yielded the divisions 205–226, the 5th Guard Div., the 3rd Marine Div., and the Bavarian divisions 14th, 16th, and 19th Reserve—in all 27, apart from some additional Landwehr divisions obtained in the same way. Certain divisions, which lost not one but two regiments in this regrouping process, were compensated by new regiments numbered 389–400, 417–441 and 477, these being formed by grouping experienced companies taken from existing regiments of every kind. Somewhat later, on the verge of the offensive of Caporetto, the Jäger battalions still available and unallotted were grouped in a "Jäger Division," the last high-quality formation created in the war. (*c*) The creation of a series of new divisions, in somewhat the same way as the old first and second new reserves, at training camps in Germany. The quality of these was, however, far below that of the new armies of 1914. Although 50% were returned wounded men and men drafted back from the fronts, the remainder were of the class 1918, called up nearly two years in advance. (*d*) The numbers of these divisions were 231–242 and 15th Bav. (regiments 442–476, and 30–32 Bav.). At the time of the creation of these, the old 8th Ersatz Div. took the number 243. The creation of a series of divisions for home defences and garrison duty, which in effect were only groupings of existing Landsturm (in some cases Landwehr) resources. Of these only the 251st, 252nd, and 253rd were actually formed as such. The Metz mobile reserve which had existed since Aug. 1914, was numbered into this series; later it was freed from all connexion with the fortress, and a new Metz mobile reserve was formed in the last months of the war.

These measures, in their ensemble, increased the number of divisions or "equivalents" (the last being by now very few) from 172 to 213 in Jan. 1917, and 223 in May 1917, the final total reached being 238 in Oct. 1917. The 1917 class, the combed men of March 1916, and the soldiers who could be claimed from back areas, by no means sufficed to cover the needs of these new formations, at the same time as they made good the losses of Verdun, the Somme, Rumania and Russia, not to mention Arras and the Aisne. Already in Aug. 1916 there began the examination muster of the 1918 class, and by mid-November it began to join for training, though not one of its members had reached the age of 19. By now, too, the effective value of a "class" had sunk considerably, because of the percentage which had to be rejected not only for immaturity but for malnutrition as well.

The ration strength of the army, taken on the same basis as the previous figures, had grown by March 31 1917 to 7,630,456, but the loss of 311,034 killed, 26,016 dead of disease, 192,380 missing and about 250,000 disabled (of 875,107 wounded), in all about 775,000, had compelled the recruiting authorities to find some 1,643,000 recruits in the 12 months. And it was precisely at this period (Oct. 1916) that, under the energetic pressure of Hindenburg and Ludendorff—who had succeeded Falkenhayn at the moment of the Rumanian crisis—a great munition production campaign was started in Germany, which necessitated the recall to the factories of a large number (125,000 men in the armies '16–17) of mobilized workmen and a check to the process of combing-out. On the eve of the battle of the Somme, the strength of the German army in *combatants only* was 2,260,000 in the W. and 590,000 in the E., or (neglecting the small forces in the Balkans and Turkey) 2,850,000 on all fronts.

In spite of the fact that the line had held both in the W. and in the E. and that Rumania, with its material resources, had been conquered into the bargain, the outlook for 1917 was dark. The Russian Revolution came, with its enigmas; unrestricted submarine warfare was proclaimed with the foreseen result of bringing America into the war on the side of the Entente; and the British and French offensive was planned in a hope, almost amounting to certainty, that the defence would break down. Skilful defence, and sins of omission and commission on the side of the Entente, weathered this crisis for Germany, with a lower figure of losses than in any previous year; and Hindenburg and Ludendorff were able to collect such free reserves as allowed them to check the last Russian offensive, inflict two defeats which ended the war in the E., and to carry through the Caporetto offensive that so nearly ruined Italy.

This they were enabled to achieve—so far as the factors were under their own control—by using up the class of 1918, by creating as many manœuvre units as possible, by employing every means that presented itself to stiffen the sinking *moral* of the war-weary army, and by new tactical methods, of which the most characteristic element was the light machine-gun. These guns were already in the spring of 1917 available on the scale of three per company. By the close of the year most companies had six, and during 1918 the issue of both light and heavy machine-guns for defence against low-flying aeroplanes was extended to batteries and to transport columns of every sort. Heavy machine-guns, too, had risen in number to one company of 10–12 guns per infantry battalion, besides those of the divisional "M.G. Sharpshooter detachment" which numbered 36.

The characteristic of the army of 1917–8 therefore became economy of man-power, through constant augmentation of machine-gun power. Whereas in 1914 a 12-battalion active division possessed 24 machine-guns, in the winter of 1917–8 a 9-battalion division possessed 216 light and 142 heavy, or 358 in all. The rifle strength of the standard battle unit had been halved, and the machine-gun strength multiplied 15 times in about three and a half years, even without taking anti-aircraft machine-guns into account. The ratio of fire-power to men exposed had very nearly trebled.

At this point, when the stage was being set for the final act, it is desirable to summarize in tabular form the number and distribution of German divisions (and "equivalents") during the first three years in which manœuvre on interior lines was constant. Table D forms, rightly understood, a summary of the history of the World War, so far as Europe is concerned. Directly or indirectly, it reflects all its vicissitudes.

Amongst these divisions a certain classification in respect of quality had been set up. In 1914 Landwehr and Ersatz and new reserve formations had been differentiated from active and reserve and from each other in composition and rôle, but with the constant and, till 1917, somewhat haphazard replacements of casualties, differences based on provenance had disappeared. Instead, differences based on battle experience had come into force, and though largely accidental at the outset, they had become effective through the machinery of replacements. Divisions recognized as "shock-troops" (a legacy of the trench-warfare period) were dignified by the name of *Grosskampfdivisionen* in their offensive aspect and *Eingreifsdivisionen* ("Intervention" or counter-attack divisions) on their defensive; and they received the pick of the recruits and returned wounded. The rest, formations fit to hold the line merely, were currently called "sector" divisions, and received, in the main, less battle-worthy elements in their drafts. A real, though admittedly undesirable, distinction was thus established. The Entente intelligence staff rated the 203 divisions of the western front with which it was concerned in 1918 thus: 61 "very good," 103 "average," 22 "poor."

The difference was not reflected in organization, except in the sense that "shock" divisions were the first to be equipped to any new scale that had been decided upon. Thus, such divisions were the first to receive their complement of six light machine-guns per company. In 1918 they received a fuller allowance of transport, and also, as part of their "organic" artillery, a group of medium guns (two batteries 15-cm. howitzers and one battery 10-cm. long guns) in addition to their field artillery.

Otherwise, the equipment and organization of all the divisions assembled in France in March 1918 was the same:—three infantry regiments, each regiment with its three battalions, three machine-gun companies, and three light Minenwerfer detachments, the whole under an infantry brigade staff; one field artillery regiment of two groups guns and one group howitzers (in all nine batteries), which (with sector artillery or reënforcing artillery) was under the divisional artillery staff; (one M.G. Sharpshooter detachment of 36 M.G.); three heavy and medium Minenwerfer batteries which, a little later, were reformed, with the light M.W. units, as infantry regimental companies. In the case of attack divisions, a group of three batteries of medium artillery was included organically and up to 40 or 45 army batteries attached for the purposes of a particular battle. In one respect only was material preparation wanting. Tanks were not looked upon with favour, only a few units being constituted.

All cavalry divisions in the W. were dismounted and acting as infantry in quiet parts of the line. They were in process of reconstitution as infantry under the name of Schützen.

The divisions in line were under corps staffs which though long fixed in sector still retained the old numbers they had had in the open warfare of 1914–5, with a district or personal designation (*e.g.* Gruppe Lille, Gruppe Conta) as well. Certain corps staffs numbered above 50, which had neither troops nor home regions of their own, had been created in 1915–6 as reserve headquarters available for the control of particular operations. The corps or "group" were allotted to armies which from right to left (sea to Switzerland) were as follows:—IV. (Flanders), VI. (Artois), XVII. (Artois), II. (Picardy), XVIII. (N. of Oise), VII. (S. of Oise), I. (Reims), III. (Champagne), V. (Verdun); and thence to the Swiss border a series of army groups (small armies) known as C., XIX. Army, A., B.

These armies were grouped in groups of armies (*Heeresgruppen*) known by the names of their commanders—Prince Rupprecht (IV., VI., XVII., II.), German Crown Prince (XVIII., VII., I., III.), Gallwitz (V., C.), Duke Albrecht (XIX., A., B.). During Aug. 1918 a Heeresgruppe Boehn was created, between Rupprecht and the German Crown Prince, comprising the XVIII., the IX. (staff brought over from Russia) and the VII., but did not last long. The XVIII. Army was then assigned to Rupprecht and the IX. staff was withdrawn, and the VII. returned to the German Crown Prince's group of armies.

Some 40 divisions remained on the eastern front to overawe the Soviet Government to "prevent the formation of an Anglo-Bolshevik front," and to occupy the corn lands of S. Russia. These were gradually "milked" of their best elements, and had a reduced artillery strength.

At this date (end of March 1918) the ration strength of the whole German army had increased to 7,917,170. The losses of the period April 1 1917 to March 31 1918—which must include some at any rate of the casualties of the "Michael" offensive—had been 257,748 killed, 37,004 died of disease, 138,070 missing, 679,777 wounded; and the "definitive" losses may be taken at 650,000. Comparison of these figures with those for 1916–7 gives a measure of the relief which was afforded to Germany by the success of her defence and the breakdown of the Entente's 1917 offensive. Only about 900,000 recruits had to be found instead of 1,600,000 as in 1916–7. Recruiting policy was accordingly less desperate. The 1919 class was called to the colours without haste—though still two years in advance of the proper time—trained carefully, and acclimatized to war conditions on the quiet Russian front, in the winter of 1917–8. It was regarded by Ludendorff collectively as the means of replacing the casualties to be expected in his great offensive. A great effort was made by drastic combing-out of industries not only to obtain combatants but also substitutes for every battle-fit man who was still serving in rear areas and on quiet fronts. Even the Alsatians and Lorrainers, hitherto employed almost exclusively on the eastern front, were to be brought over and incorporated in Rhineland units, in whose provincial patriotism it was thought that the Alsatians and Lorrainers might be brought to share. This was only an extension of a practice which had already been begun in 1916 of re-sorting the personnel of units according to their province of origin, as in the pre-war army.

The *moral* of the army was still good. In spite of war-weariness, it was felt that in one last effort peace could be won. For the first time the Germans enjoyed a numerical superiority and leisure for thorough battle training. If at home discontent was ready to break out in revolt, the effects were not at that period felt at the front, owing to an industrious propaganda, assiduous "welfare work," and largely to the disappearance of peace-time social barriers between men and officers—the latter, indeed, being now for the most part either commissioned or made acting officers from the ranks.

The offensive of March 1918 was launched, and was successful, but at heavy cost, and it did not win the war. Others followed it, always with the same result. By the end of April the 1919 class was largely absorbed, and preparations were being made for the call-up of the 1920 class. By the end of July 1919 men were practically exhausted, and the now incessant battle casualties had to be made good by returned wounded. Meantime

impossible to carry out regrouping with the smooth regularity of March 1915; the measures taken, therefore, extend over the whole period. They were as follows: (*a*) The constitution of new divisions (201–204 and 12th Bav.) out of odd units existing in various theatres and of "combings" obtained in the lines of communication, the Ersatz battalions and other military establishments in Germany. The infantry regiments of these divisions were numbered 401–416 and 26–28 Bavarian. (*b*) The regrouping of all old divisions still remaining on the 4-regiment basis as 3-regiment formations of the new standard type—*i.e.* the completion of the process which had been half carried out in March 1915. This yielded the divisions 205–226, the 5th Guard Div., the 3rd Marine Div., and the Bavarian divisions 14th, 16th, and 19th Reserve—in all 27, apart from some additional Landwehr divisions obtained in the same way. Certain divisions, which lost not one but two regiments in this regrouping process, were compensated by new regiments numbered 380–400, 417–441 and 477, these being formed by grouping experienced companies taken from existing regiments of every kind. Somewhat later, on the verge of the offensive of Caporetto, the Jäger battalions still available and unallotted were grouped in a "Jäger Division," the last high-quality formation created in the war. (*c*) The creation of a series of new divisions, in somewhat the same way as the old first and second new reserves, at training camps in Germany. The quality of these was, however, far below that of the new armies of 1914. Although 50% were returned wounded men and men drafted back from the fronts, the remainder were of the class 1918, called up nearly two years in advance. (*d*) The numbers of these divisions were 231–242 and 15th Bav. (regiments 442–476, and 30–32 Bav.). At the time of the creation of these, the old 8th Ersatz Div. took the number 243. The creation of a series of divisions for home defences and garrison duty, which in effect were only groupings of existing Landsturm (in some cases Landwehr) resources. Of these only the 251st, 252nd, and 253rd were actually formed as such. The Metz mobile reserve which had existed since Aug. 1914, was numbered into this series; later it was freed from all connexion with the fortress, and a new Metz mobile reserve was formed in the last months of the war.

These measures, in their ensemble, increased the number of divisions or "equivalents" (the last being by now very few) from 172 to 213 in Jan. 1917, and 223 in May 1917, the final total reached being 238 in Oct. 1917. The 1917 class, the combed men of March 1916, and the soldiers who could be claimed from back areas, by no means sufficed to cover the needs of these new formations, at the same time as they made good the losses of Verdun, the Somme, Rumania and Russia, not to mention Arras and the Aisne. Already in Aug. 1916 there began the examination muster of the 1918 class, and by mid-November it began to join for training, though not one of its members had reached the age of 19. By now, too, the effective value of a "class" had sunk considerably, because of the percentage which had to be rejected not only for immaturity but for malnutrition as well.

The ration strength of the army, taken on the same basis as the previous figures, had grown by March 31 1917 to 7,630,456, but the loss of 311,034 killed, 26,016 dead of disease, 192,380 missing and about 250,000 disabled (of 875,107 wounded), in all about 775,000, had compelled the recruiting authorities to find some 1,643,000 recruits in the 12 months. And it was precisely at this period (Oct. 1916) that, under the energetic pressure of Hindenburg and Ludendorff—who had succeeded Falkenhayn at the moment of the Rumanian crisis—a great munition production campaign was started in Germany, which necessitated the recall to the factories of a large number (125,000 men in the armies '16–17) of mobilized workmen and a check to the process of combing-out. On the eve of the battle of the Somme, the strength of the German army in *combatants only* was 2,260,000 in the W. and 590,000 in the E., or (neglecting the small forces in the Balkans and Turkey) 2,850,000 on all fronts.

In spite of the fact that the line had held both in the W. and in the E., and that Rumania, with its material resources, had been conquered into the bargain, the outlook for 1917 was dark. The Russian Revolution came, with its enigmas; unrestricted submarine warfare was proclaimed with the foreseen result of bringing America into the war on the side of the Entente; and the British and French offensive was planned in a hope, almost amounting to certainty, that the defence would break down. Skilful defence, and sins of omission and commission on the side of the Entente, weathered this crisis for Germany, with a lower figure of losses than in any previous year; and Hindenburg and Ludendorff were able to collect such free reserves as allowed them to check the last Russian offensive, inflict two defeats which ended the war in the E., and to carry through the Caporetto offensive that so nearly ruined Italy.

This they were enabled to achieve—so far as the factors were under their own control—by using up the class of 1918, by creating as many manœuvre units as possible, by employing every means that presented itself to stiffen the sinking *moral* of the war-weary army, and by new tactical methods, of which the most characteristic element was the light machine-gun. These guns were already in the spring of 1917 available on the scale of three per company. By the close of the year most companies had six, and during 1918 the issue of both light and heavy machine-guns for defence against low-flying aeroplanes was extended to batteries and to transport columns of every sort. Heavy machine-guns, too, had risen in number to one company of 10–12 guns per infantry battalion, besides those of the divisional "M.G. Sharpshooter detachment" which numbered 36.

The characteristic of the army of 1917–8 therefore became economy of man-power, through constant augmentation of machine-gun power. Whereas in 1914 a 12-battalion active division possessed 24 machine-guns, in the winter of 1917–8 a 9-battalion division possessed 216 light and 142 heavy, or 358 in all. The rifle strength of the standard battle unit had been halved, and the machine-gun strength multiplied 15 times in about three and a half years, even without taking anti-aircraft machine-guns into account. The ratio of fire-power to men exposed had very nearly trebled.

At this point, when the stage was being set for the final act, it is desirable to summarize in tabular form the number and distribution of German divisions (and "equivalents") during the first three years in which manœuvre on interior lines was constant. Table D forms, rightly understood, a summary of the history of the World War, so far as Europe is concerned. Directly or indirectly, it reflects all its vicissitudes.

Amongst these divisions a certain classification in respect of quality had been set up. In 1914 Landwehr and Ersatz and new reserve formations had been differentiated from active and reserve and from each other in composition and rôle, but with the constant and, till 1917, somewhat haphazard replacements of casualties, differences based on provenance had disappeared. Instead, differences based on battle experience had come into force, and though largely accidental at the outset, they had become effective through the machinery of replacements. Divisions recognized as "shock-troops" (a legacy of the trench warfare period) were dignified by the name of *Grosskampfdivisionen* in their offensive aspect and *Eingreifsdivisionen* ("Intervention" or counter-attack divisions) on their defensive; and they received the pick of the recruits and returned wounded. The rest, formations fit to hold the line merely, were currently called "sector" divisions, and received, in the main, less battle-worthy elements in their drafts. A real, though admittedly undesirable, distinction was thus established. The Entente intelligence staff rated the 203 divisions of the western front with which it was concerned in 1918 thus: 61 "very good," 103 "average," 22 "poor."

The difference was not reflected in organization, except in the sense that "shock" divisions were the first to be equipped to any new scale that had been decided upon. Thus, such divisions were the first to receive their complement of six light machine-guns per company. In 1918 they received a fuller allowance of transport, and also, as part of their "organic" artillery, a group of medium guns (two batteries 15-cm. howitzers and one battery 10-cm. long guns) in addition to their field artillery.

Otherwise, the equipment and organization of all the divisions assembled in France in March 1918 was the same:—three infantry regiments, each regiment with its three battalions, three machine-gun companies, and three light Minenwerfer detachments, the whole under an infantry brigade staff; one field artillery regiment of two groups guns and one group howitzers (in all nine batteries), which (with sector artillery or reënforcing artillery) was under the divisional artillery staff; (one M.G. Sharpshooter detachment of 36 M.G.); three heavy and medium Minenwerfer batteries which, a little later, were reformed, with the light M.W. units, as infantry regimental companies. In the case of attack divisions, a group of three batteries of medium artillery was included organically and up to 40 or 45 army batteries attached for the purposes of a particular battle. In one respect only was material preparation wanting. Tanks were not looked upon with favour, only a few units being constituted.

All cavalry divisions in the W. were dismounted and acting as infantry in quiet parts of the line. They were in process of reconstitution as infantry under the name of Schützen.

The divisions in line were under corps staffs which though long fixed in sector still retained the old numbers they had had in the open warfare of 1914–5, with a district or personal designation (*e.g.* Gruppe Lille, Gruppe Conta) as well. Certain corps staffs numbered above 50, which had neither troops nor home regions of their own, had been created in 1915–6 as reserve headquarters available for the control of particular operations. The corps or "group" were allotted to armies which from right to left (sea to Switzerland) were as follows:—IV. (Flanders), VI. (Artois), XVII. (Artois), II. (Picardy), XVIII. (N. of Oise), VII. (S. of Oise), I. (Reims), III. (Champagne), V. (Verdun); and thence to the Swiss border a series of army groups (small armies) known as C., XIX. Army, A., B.

These armies were grouped in groups of armies (*Heeresgruppen*) known by the names of their commanders—Prince Rupprecht (IV., VI., XVII., II.), German Crown Prince (XVIII., VII., I., III.), Gallwitz (V., C.), Duke Albrecht (XIX., A., B.). During Aug. 1918 a Heeresgruppe Boehn was created, between Rupprecht and the German Crown Prince, comprising the XVIII., the IX. (staff brought over from Russia) and the VII., but did not last long. The XVIII. Army was then assigned to Rupprecht and the IX. staff was withdrawn, and the VII. returned to the German Crown Prince's group of armies.

Some 40 divisions remained on the eastern front to overawe the Soviet Government to "prevent the formation of an Anglo-Bolshevik front," and to occupy the corn lands of S. Russia. These were gradually "milked" of their best elements, and had a reduced artillery strength.

At this date (end of March 1918) the ration strength of the whole German army had increased to 7,917,170. The losses of the period April 1 1917 to March 31 1918—which must include some at any rate of the casualties of the "Michael" offensive—had been 257,748 killed, 37,004 died of disease, 138,070 missing, 679,777 wounded; and the "definitive" losses may be taken at 650,000. Comparison of these figures with those for 1916–7 gives a measure of the relief which was afforded to Germany by the success of her defence and the breakdown of the Entente's 1917 offensive. Only about 900,000 recruits had to be found instead of 1,600,000 as in 1916–7. Recruiting policy was accordingly less desperate. The 1919 class was called to the colours without haste—though still two years in advance of the proper time—trained carefully, and acclimatized to war conditions on the quiet Russian front, in the winter of 1917–8. It was regarded by Ludendorff collectively as the means of replacing the casualties to be expected in his great offensive. A great effort was made by drastic combing-out of industries not only to obtain combatants but also substitutes for every battle-fit man who was still serving in rear areas and on quiet fronts. Even the Alsatians and Lorrainers, hitherto employed almost exclusively on the eastern front, were to be brought over and incorporated in Rhineland units, in whose provincial patriotism it was thought that the Alsatians and Lorrainers might be brought to share. This was only an extension of a practice which had already been begun in 1916 of re-sorting the personnel of units according to their province of origin, as in the pre-war army.

The *moral* of the army was still good. In spite of war-weariness, it was felt that in one last effort peace could be won. For the first time the Germans enjoyed a numerical superiority and leisure for thorough battle training. If at home discontent was ready to break out in revolt, the effects were not at that period felt at the front, owing to an industrious propaganda, assiduous "welfare work," and largely to the disappearance of peace-time social barriers between men and officers—the latter, indeed, being now for the most part either commissioned or made acting officers from the ranks.

The offensive of March 1918 was launched, and was successful, but at heavy cost, and it did not win the war. Others followed it, always with the same result. By the end of April the 1919 class was largely absorbed, and preparations were being made for the call-up of the 1920 class. By the end of July 1919 men were practically exhausted, and the now incessant battle casualties had to be made good by returned wounded. Meantime

numerical superiority disappeared with the accelerated arrival of American divisions in France. By July 1 the rifle strength of the Germans was 100,000 below that of the Allies. Two Austrian divisions, and converted cavalry divisions, which were brought into action during the summer, were hardly more than a drop in the bucket. Company strengths could no longer be maintained. More and more the army became an army of machine-gunners, practising the infiltration method in attack and the elastic method in defence, but in its growing disillusionment becoming less and less apt for either form, since both demanded a high *moral* in the isolated squad which formed the fighting unit.

As early as May it was decided to break up certain formations and to use their personnel as drafts for others. This process was carried out on a large scale from the end of July; 13 divisions disappeared by the end of Aug., 10 more in Sept. and 3 more in the first days of Oct. The 1920 class, called up and trained, reached the field depots from Aug. onwards, but for political reasons sanction was refused for its employment in the front line. This was the last resource, for unless a winter's respite could be obtained, the most complete combing-out of home industries and agriculture—now in any case impossible owing to the political situation—would not have yielded a sufficient supply of trained combatants.

The sinking of *moral* in the army manifested itself in the "black day" of Aug. 8. During that month and Sept., in spite of the stout resistance of many formations, the sentiment of defeat spread. At the last a final effort of propaganda convinced the army that by fighting hard, and only so, it might obtain honourable terms of peace. But it was too late. The end had come in Germany.

With the evacuation of occupied territory and the march home to demobilization—in most cases self-demobilization—the history of the Prussian and German army system built up by Frederick the Great, Scharnhorst and Moltke, came to an end.

The losses in the concluding year, from April 1 1918 to March 31 1919, are stated at 303,023 killed, 48,751 died of disease, 334,802 missing, and 823,498 wounded, representing a "definitive" loss of about 940,000.

In the whole war, the losses amounted to 1,531,048 killed, 155,013 died of disease, 991,340 missing, 4,211,469 wounded; or a total of 6,888,870 for recorded military casualties.

(C. F. A.)

IX.—The Austro-Hungarian Army

Till a few years before the World War it could be said that no great state took as little care for its army as the Dual Monarchy. National differences and constant party conflict prevented anything more than the barest necessities of maintenance being provided for, and stagnation and even retrogression ruled in the army itself in consequence. This was especially true during the period 1903–6, in which the constitutional conflicts in Hungary focussed themselves principally upon the question of the Common Army and led to difficulties of which the consequences were serious indeed. There were, however, in the last few years two causes at work which led to important developments. The first of these was the eternal Balkan question, which on two occasions—the Annexation Crisis of the spring of 1909 and the Balkan War of 1912–3—brought Austria-Hungary to the verge of war. Each time Austria-Hungary was unready for war. But the long-deferred modernization of the military system was, under the pressure of circumstances, taken in hand, at any rate so far as patching up the more obvious defects was concerned.

The greatest sins of omission in the past had been those affecting the artillery; the danger of war in the south-east led to these being repaired, at any rate so far as the limited means allocated allowed of it, and also to machine-guns being provided. The latter had been under experiment with cavalry and mounted troops since 1903, and it was not until 1908 that their employment became general.

The second important influence was that of the two-years'-service scheme introduced in July 1912 This was only brought into effect after a prolonged parliamentary conflict, for the Hungarian opposition had used the opportunity to try to obtain, by tactics of obstruction, the separation of the Common Army into two parts, and, at the least, the acceptance of Hungarian as a language of command. In these struggles the ministerial party finally had its way, but the reforms it sought to bring about were shorn in the process of most of their efficacy. Indeed, so low was the agreed peace effective of the units that the army, compared with those of the other military powers, might fairly be regarded as having a militia character. The two-years'-service principle was, however, made law and applied to all parts of the armed forces of the Dual Monarchy.

These parts were five in number: (*a*) the Common or Imperial and Royal (K.u.K.) Army; (*b*) the Imperial Royal (K.K.) Austrian Landwehr; (*c*) the Royal Hungarian Landwehr (Honved); (*d*) the Austrian (K.K.), and (*e*) the Royal Hungarian Landsturms. The basic principle of this partition was that the Common Army would form the first line in an external war, the two Landwehrs the second, and the two Landsturms the third. An especial function of the last named was the garrisoning of fortresses and duty on lines of communication and in the interior. But in the last 20 years before 1914 the two Landwehrs had been brought on to the same organic and tactical level as that of the Common Army, excepting only that their peace effective within the unit was considerably lower. They were therefore in 1914 fit to be put into the first line at the outset, like the Common Army—as indeed it was essential that they should be, in view of the enormous numerical superiority that had to be faced. As it turned out, even the Landsturm, which had no peace-time existence at all, was sent into action at once, newly formed and ill equipped, on many parts of the front. The enthusiasm of the younger and the quiet resolution of the older Landsturm men, however, showed their worthiness in spite of all defects. But the experiment was a costly one in lives.

At the outbreak of war in 1914 the constitution of these forces was as follows: under the Supreme Command of the Emperor, and the direction of the War Ministry for the Common Army (and the Navy), the Austrian Ministry of Defence for the K.K. Landwehr and Landsturm, and the Hungarian "Honved Ministry" for the Honved and Hungarian Landsturm. There were six general inspectorates, and 16 corps commands each with its own territorial region.

Common Army.—Infantry: 32 Inf. Troops Divs. (I.T.D.), each of 12–16 battalions and 7–8 batteries with 74 inf. or mountain bdes. Cavalry: 8 Cav. Troops Divs. (K.T.D.), each of 24 squadrons and 3 batteries; 19 cav. bdes. Artillery: 14 field and 3 mountain bdes., 42 field-gun regts. (each 5·6 batteries and a depot cadre), 14 field-howitzer regts. (each 4 batteries and a depot cadre), 14 heavy-howitzer divs. (each of 2 batteries), 10 horse-artillery divs. (each of 3 batteries), 10 mountain-artillery regts. (each of 4 batteries of guns or howitzers, and depot cadre). Fortress artillery: 5 bdes.; 6 regts. (each of 2–3 battalions, and depot cadre); 8 independent battalions. Technical troops: 14 sapper battalions, 8 pioneer battalions; one railway and one telegraph regt.; bridging battalion; flying depot cadre. Train: 16 battalions and mechanical transport cadres.

K.K. Landwehr.—Infantry: 8 Landwehr divs.; 16 bdes.; 40 Schützen (Landesschützen) regts. (as in Common Army but of 3 battalions each). Cavalry: one cav. div.; 2 bdes.; 6 regts. mounted Schützen (organized as Common Army cav. regts.) detachments each of 3 squadrons in Tirol and Dalmatia. Artillery: 8 divs. field howitzers (each of 2 batteries).

Honved.—Infantry: 7 district divs., and one non-territorial div.; 16 bdes.; 28 regts. (each of 3 battalions). Cavalry: 2 cav. divs.; 4 cav. bdes.; 10 cav. regts. (organized as in Common Army). Artillery: 2 field-gun regts. (each of 8 batteries and depot cadre).

The infantry was armed with the 1895 8-mm. magazine rifle, except in the case of third-line units which were largely armed with rifles of the 86, 86/88, and 90/91 patterns. The field gun was an 8-cm. Q.F., the field howitzer a 10-cm., of old model (as were also the heavy howitzers), but of good power. All these guns were of steel-bronze and therefore inferior, especially in range, to those of other powers. The siege artillery included 12-cm. guns, 24-cm. mortars, and 30·5-cm. tractor-drawn mortars—the last-named remarkable weapons which found employment in field as well as in siege warfare. There were, further, the fortress armaments. The cavalry was uniformly equipped (sword and carbine), and well horsed. Theoretical training was

carried to a very high degree, but its application to practice was not perfect. The directing organs—General Staff, Intendance—were adequate and well trained.

In general it may be said that no army suffered from such unfavourable conditions for the formation and development of a sound and uniform military spirit as the Austro-Hungarian. All the more remarkable, then, is its actual performance in the World War, a performance which, in view of the handicaps, must be regarded as unique in history and can only be explained by the existence of a sentiment of military virtue, rooted in age-long traditions, which carried the army through to the very end.

Mobilization.—In spite of the fairly evident attitude of Russia, it was hoped in Austria-Hungary that the crisis of 1914 would be confined to a war against Serbia and Montenegro. Three armies were formed in the south-east. But when on July 30 the first combats were taking place on the Drina and the strategic deployment was in full swing, Russia came on the scene. The mobilization, hitherto partial only, became general, and the bulk of the forces of the Dual Monarchy formed up in Galicia, nine corps proceeding thither direct while three corps already engaged against the Serbs, or about to do so, were drawn off to the north. Mobilization and concentration, as such, were carried out without a hitch, and the transfer of the II. Army to the N. also produced no delays worth mentioning.

Infantry during the War.—The infantry worthily sustained its part as the "keystone of battle," and this is true not only of those serving with the colours at the outbreak of war but of reservists, Landwehr men, Landsturm men of all kinds who far surpassed expectations. Apart from inconsiderable changes, the infantry organization of 1914 was much the same as in 1910. The peace effective had, however, been augmented by the increase in the recruit contingent. New drill regulations had appeared in 1911, and new field-service regulations in 1912.

In Aug. 1914 the Common Army included 102 infantry regts., 4 Bosno-Herzegovinian regts., 4 Tirolese Kaiserjäger regts. (all at 4 four-company battalions), also 29 Feldjäger battalions, one Bosn.-Herz. Feldjäger battalion, and 6 frontier companies in Bosnia and Herzegovina. The first reënforcement to replace casualties was provided for by 28 "march" regts., which followed the army into the field. The Austrian Landwehr had 37 inf. and 3 Tirolese Landesschützen regts., and the Honved, 32 inf. regts.—all these being on a 3-battalion footing. The Austrian Landwehr possessed no "march" regiments, the Honved on the contrary had 16. On the outbreak of war, from the 1st and 2nd bans of the Landsturm there were formed 38 Austrian and 32 Hungarian Landsturm regiments, as well as many independent Landsturm units, the number of which was temporarily augmented later when the Landsturm age limits were extended to 18–55 years.

Battalion strength was about 1,000 rifles, except in march battalions, which varied from 800 to 1,000, and in Landsturm battalions which rarely exceeded 800.

Reenforcements were provided for in the war by sending up monthly one march battalion per regiment. Thus, in the course of the war, 48 march battalions were sent into the field for each infantry regiment. Five regiments (including the 3 Tirolese) of the Austrian Landwehr were organized as mountain troops. Independent Jäger battalions were organized like infantry battalions, and had "march companies" as their reënforcement organ. Machine-gun detachments had been in process of formation for some years, and by 1913 all infantry battalions (and cavalry divisions) had them. The detachment was of 2 guns in the case of the infantry, 4 in those of the cavalry. In 1915 Landsturm machine-gun detachments were gradually formed for certain Landsturm battalions. In 1916 the number of guns in a detachment was doubled, in 1917 trebled. The last year also saw the introduction of the hand machine-gun (light machine-gun), each battalion forming a *Zug* of four *Schwarme* (squads), each *Schwarm* having 2 guns.

The introduction of new methods and weapons in the war, of course, led in due course to the grenade, the shrapnel helmet and the gas mask being added to the infantryman's equipment. At the outset of the war regiments and independent battalions had pioneer sections, but the available stores were inadequate and had at once to be increased. After 1916 the pioneer sections were expanded into "technical companies" (one per regiment or independent battalion) and consisting each of an infantry searchlight, a trench mortar and a bombthrower section. The usefulness of these units, which possessed also some bridging material, was three or four times as great as that of the original pioneer section. The telephone equipment, introduced in 1911 but treated as a stepchild, was augmented considerably in the war, and towards the end each regiment had a section and each battalion a squad (*Schwarm*) of telephones, the first named having 26 posts and 52 km. of cable, the second 6 posts and 12 km. of cable.

A further technical development was the introduction of the 37-mm. infantry gun.

Numerically, the organization of the infantry remained unchanged till the middle of 1915. In the second half of that year three Feldjäger, two Bosn.-Herz. Jäger battalions, a combined infantry regiment and the 103rd Regt. were formed, and also a number of fortress battalions for service in the Bosno-Herzegovinian forts. The last named, however, were dissolved in 1916.

In Jan. 1916 the 104th Regt., and the 4th–8th Bosn.-Herz. Jäger battalions were created. In June the frontier companies were expanded into battalions and in Sept. the 5th Bosn.-Herz. regt. was formed. In Jan. 1917 the 29th and 37th reserve infantry regts., the 105th–109th infantry regts., and some combined "half-regiments" were created from various sources.

The creation of all these units was more or less in the nature of a temporary expedient imposed by the necessity of manning an ever-growing front. It was evidently desirable to systematize the process of expansion, and therefore in Oct. 1917 a complete reorganization of the infantry was taken in hand, concurrently with a reorganization of the infantry division itself. All regiments were now uniformly organized on a three-battalion footing, and from the fourth battalions available and the four newest Bosn.-Herz. Jäger battalions, new three-battalion regiments were created. At the beginning of 1918, therefore, there were 138 infantry, 4 Tirolese Kaiserjäger, and 8 Bosn.-Herz. regts., each of three battalions. In May 1918 a 139th regt. was added. The number of Feldjäger battalions, the (four) Bosn.-Herz. Jäger battalions and the frontier Jäger battalions remained the same.

In the Austrian Landwehr there was no change in numbers, but in the spring of 1917 the regiments were renamed Schützen regiments, the Tirolese Landesschützen became Kaiserschützen, and the two Austrian regiments, 4th and 27th, formed as mountain troops, were renamed 1st and 2nd mountain regiments. The Hungarian Landwehr (officially styled Honved after the spring of 1917) formed in the course of the war 17 new regiments, numbered 300–316. At the end of the war the Landsturm formations in existence were 15 regiments, 41 independent battalions, 4 Tirolese battalions, and in Hungary 8 regiments and 16 independent battalions. Lastly there were 91 Austrian and 65 Hungarian Landsturm line-of-communication battalions.

Storm Battalions.—Patrols (squads) of picked men trained to grenade work and employed for special enterprises were already in existence in the spring of 1916, especially on the Isonzo front. These were followed in the latter part of 1917 by storm troops proper, and at the beginning of 1918 each infantry division headquarters possessed a storm battalion and each cavalry division headquarters and each independent infantry brigade a corresponding unit, all these being formed from the storm troops of regiments, brigades, etc.

High mountain and guide companies were formed to train guides for troops engaged in the more difficult Alpine work. These numbered 20 and 13 respectively at the end of the war. *Cyclist* units existed even before the war (Jan. 1912), four companies from certain Jäger battalions being assembled as a unit. This unit did very well, and in the war cyclist battalions were created in the Hungarian Honved, in both Landsturms (and in the Navy). Early in 1918 the three battalions were named 1st and 2nd, and Honved cyclists.

Cavalry.—The Austro-Hungarian cavalry was, according to the ideas and standards prevailing before the war, superbly trained. Officers, men and horses were first-class. But the ideas and standards were out-of-date. The principle of using cavalry as a battle-arm still prevailed, whereas the Russian cavalry, having absorbed the lessons of the most recent wars, rarely showed themselves in big masses, but worked in mixed groups consisting of cavalry, machine-gun detachments, artillery and cyclists.

In 1910 Austria-Hungary had possessed eight cavalry divisions of the Common Army, to which in 1912 were added two Honved cavalry divisions, and on the outbreak of war a 9th Cav. Div. formed in the Austrian Landwehr. The regiments were: 15 Dragoon, 16 Hussar, 11 Ulan, 6 K.K. Lwhr. Ulan (these renamed mounted Schützen in 1917), 10 Hungarian Honved Hussar regts., and smaller units in Tirol and Dalmatia. At the outbreak of war Hungary formed 10 Hussar half-regts. of Landsturm. In each regiment further 1st and 2nd reserve squadrons were formed. The bulk of this mounted force was grouped in 11 divisions (at 4 regiments per division) and the rest, including the reserve squadrons, allotted in pairs or threes as divisional cavalry to the infantry divisions or corps. The rôle of the cavalry divisions was exploration and screening, that of the divisional squadrons liaison and local scouting with the infantry. In both cases the performance of these functions met with unexpectedly great difficulties owing to the thoroughly modern tactics employed by the Russian cavalry, which employed all the methods of dismounted fire fighting and rarely came to open mounted shock. This imposed at once a restriction in the cavalry methods of the Austrians. Little stress had been laid on fire fighting in peace, but when position warfare set in in 1915, and still more when horses became scarce in 1917, mounted work fell more and more into the background. The equipment was revolutionized. The soldier was provided with wire cutters, grenades, obstacle material, etc. Already in the spring of 1915 the unserviceable uniforms of peace-time had given way to grey. The useless sabre was replaced by the bayonet.

Thus, and in other ways, the arm rapidly adjusted itself to the new conditions. Even in the winter 1914–5 certain formations had

created dismounted sections, and these in time became the basis of Schützen *divisionen* of cavalry, analogous to infantry battalions.

In the winter 1917–8 a thorough reorganization was carried out. The regiment which at the outset had comprised 6 squadrons of 150 sabres each, one pioneer section, and one telegraph patrol, was reconstituted on the basis of 2 half-regiments each of 4 squadrons dismounted; 2 machine-gun squadrons (8 guns each), 2 hand machine-gun sections and a technical squadron, besides an infantry gun section comprising 2 trench mortar squads, 2 bombthrower squads, one searchlight squad, and one cavalry telephone squad. The equipment of the individual man was assimilated to that of the infantry soldier. In each infantry and cavalry division there only remained mounted one squadron of divisional cavalry.

The cav. div., which had originally comprised 2 brigades, 4 regiments, 1–2 machine-gun detachments, and a horse artillery division (three 4-gun batteries), consisted on the new basis of one (or 2) brigade headquarters, 4 dismounted regiments, one storm regiment, one sapper section, one telegraph company (if required, one radio company) and one mounted squadron. From the available horse artillery were formed "mounted field artillery" regts., each of 2 gun, 4 howitzer, and 1 trench mortar batteries. In 1918 it was planned to create brigades of horse artillery for the cavalry divisions, each consisting of one of the horse regts. and a heavy artillery regiment.

In March 1918 a 12th (mounted Schutzen) Div. was created out of 4 regiments of that category.

Artillery.—No arm in any army was so completely transformed in the war as the Austro-Hungarian artillery. Though worthy of its ancient reputation in point of science and training, it suffered at the outset from inferior material. Whereas Russia and Serbia taking to heart the lessons of Manchuria had modernized their guns, in Austria-Hungary these necessities were burked on political and financial grounds.

It is true that the gun introduced in 1905 was a modern Q.F. equipment, equivalent to Russian and Serbian weapons of the same class. But the field and heavy howitzers, dating from 1880 and 1899 were, like the mountain guns and howitzers, obsolete and ineffective. Inadequate, too, was the fortress artillery. Apart from some 30·5-cm. mortar batteries, sent at the outbreak of war to the western front, and some 24-cm. mortar batteries, only quite obsolete guns were available.

In the years preceding the war, indeed, the most urgently necessary steps had been taken towards modernizing of the artillery. In the first place numerical increase was necessary. As against the 72–54 guns per division of other powers Austria-Hungary had only 42.

After various augmentations in the last two years the artillery consisted at the outbreak of war of 42 army, 8 Landwehr and 8 Honved field-gun regiments, each of 5 batteries (4 in the Landwehr and Honved divisions); 28 army and 8 Landwehr field howitzer divisions (each of 2 batteries); 9 army and one Honved horse artillery divisions (each 3 batteries); 14 heavy artillery divisions (each 2 batteries); 10 mountain artillery regiments (each of 4 gun and 2 howitzer batteries), and one independent mountain division[1]; 6 regiments and 7 battalions of fortress artillery.

During the war the development of the artillery was naturally ceaseless. It began with the replacement of old-pattern guns and increases in the available numbers of field guns. At the beginning of 1915 the old field and heavy howitzers were replaced by Q.F. 10-cm. and 15-cm. weapons, and a modern 10·4-cm. long gun ranging to 12 km. was brought out. Further, two completely modern mountain equipments (7·5-cm. gun and 10-cm. howitzer models 1915, ranging to 7 and 8 km.) gradually supplanted the older types.

In the course of the war the former ratio of howitzers to guns was greatly modified, till finally the former preponderated. In succession, batteries were taken from the field-gun regiments and re-formed in new howitzer regiments. The heavy howitzer divisions were augmented and in part armed with the new 15-cm. equipment, and, further, 11 10·4-cm. heavy-gun batteries, as well as some heavy howitzer divisions in both Landwehrs, were created.

By the end of 1915 the proportion of howitzers had come to be about 50%, and at the end of the war there were three times as many howitzers as there were guns.

Up to the end of 1915 the mountain artillery had been augmented by 5 regiments, the fortress artillery by one battalion, while the number of 30·5-cm. batteries increased to 20. At that date the formation was in progress of motorized batteries of 15-cm. guns and howitzers (ranging to 18 and 12 km. respectively). At the beginning of 1916 all K.K. and Hungarian Landwehr howitzer divisions were grouped, by fours in the case of the light, by threes in that of the heavy, into regiments. At the same time greater attention was paid to the anti-aircraft artillery, which received modern as well as improvised weapons.

At the end of 1916 there were: 28 army, 8 Landwehr, 8 Honved, 14 army reserve, 8 Honved reserve field-gun regiments, 9 horse artillery divisions; 28 army, 8 Landwehr, 8 Honved, 14 army reserve, 4 Landwehr [illegible] and Honved reserve field howitzer regiments; 45 anti-aircraft batteries; 30 army, 8 Landwehr, 8 Honved, 3 army reserve, one Honved reserve heavy field artillery regiments; 28 army, 4 Landwehr, 3 Honved mountain artillery regiments.

At this period the introduction of 21-cm. mortars, of 38- and 42-cm. mortars and of 24- and 35-cm. long guns into the armament of the fortress artillery was in progress. These were completely modern guns, were motorized and ranged to 15 km. in the case of the mortars and to 26–32 km. in that of the guns. Twelve trench mortar batteries were also added to the fortress artillery.

This organization remained substantially unaltered during 1917, the only noteworthy change being the transformation of the horse artillery already alluded to (summer 1917), the steady augmentation in the number of fortress batteries and the increased employment of heavy naval guns.

In connexion with the reorganization of the infantry divisions at the end of 1917 the artillery was of course recast also. In peace-time the artillery regiments, etc., had been so arranged that in each corps area an artillery brigadier commanded all units of the arm in that area. In war each infantry division had originally a brigade of artillery (one regiment field guns, one division howitzers[2]). In Feb. 1918 the organization took up its final form. The artillery regiments were uniformly reorganized with gun and howitzer batteries in each; and the designation "Field Artillery" was adopted by all. Each artillery brigade (one per division, *i.e.* 66) henceforth consisted of 2 field artillery regiments, one heavy field artillery regiment and one mountain artillery group. The field regiments had 2 gun and 3 howitzer batteries, and either a trench mortar or an anti-aircraft battery. The heavy field artillery regiment had 4–5 batteries, one only being armed with 10·4-cm. guns and the others with 15-cm. howitzers. The mountain artillery group had 2 gun and one howitzer battery.

The artillery, with cavalry divisions, was similarly reorganized and gradually provided with heavy artillery units.

After providing for the above-mentioned mountain groups, there remained 14 independent regiments of that branch. These were constituted as a G.H.Q. reserve, and each consisted of 6 gun and 3 howitzer batteries.

At the end of the war the field and mountain artillery of the Austro-Hungarian army amounted to a total of 864 light, 328 heavy, and 324 mountain batteries, as against 360 light, 28 heavy and 74 mountain at the outset.

The fortress artillery was also reorganized, and renamed "heavy artillery." Hitherto its organization had varied according to its allocation to fortresses, but thenceforward it was formed in 14 regiments each of 4 groups at 4 batteries. On the verge of the Armistice 4 independent groups were created at Trieste, in Dalmatia, and in Montenegro.

Technical Troops.—In 1893 the previously existing engineer and pioneer corps were reconstituted as a single pioneer corps carrying out all engineer duties, this corps consisted of 15 battalions. In 1912 a new subdivision was introduced. "Pioneers" were allocated to water work and "Sappers" to land and fortress work—as had been the case before 1893. The pioneer corps then consisted of 8 four-company battalions and the sapper corps of 14 three-company battalions. At the same time a special bridging battalion (for semi-permanent work) and a river-mining company were created. Both corps did their work well in the war, but they were far too small.

At the beginning of the war a 9th Pioneer Battalion was in existence, and the number of companies in each battalion had risen to 5 in the pioneer, 6 in the sapper battalions. The army was accompanied in the field by a variety of technical formations such as tool columns and mobile parks. The bridging equipment consisted of 126 units, each capable of 53 miles of bridging.

The inadequacy of numbers was made good immediately after the outbreak of war by creating Landsturm sapper companies and numerous works detachments.

In the middle of 1915 a second bridging battalion was raised, and by the end of that year trench mortar, bombthrower and electro-technical units were in existence. The pioneer battalions had now up to six companies and the sapper battalions up to ten. In 1917 a special battalion was formed for offensive gas warfare. Other technical branches were created to deal with close-combat means (air-mining, powder-mining, bombthrower sections, compressed air, oxygen and air-liquifying stations); electro-technical matters (searchlights, live-wire obstacles, accumulators, drinking water and pumping machinery, ventilators, boring tools) and other things, and these were constantly augmented.

The thoroughgoing reorganization of winter 1917–8 affected also the technical troops. The pioneers were abolished, and all technical services placed in the hands of the sappers while close-combat means and searchlights were transferred to infantry, cavalry and artillery formations. Thenceforward the sapper corps consisted of 60 three-company battalions (1 per division and the remainder to corps, etc.), 1 flamethrower battalion, and numerous bridging tool and other units. To the sappers now belonged also the well-boring and the electro.

[1] Each of the 10 regiments formed an additional battery of guns on mobilization.

[2] In the 8 K.K. Landwehr divisions an army gun regiment of 4 batteries, a Landwehr gun division of 2, and a Landwehr howitzer division of 2. In the 8 Honved divisions, 1–2 divisions of an army gun regiment and one Honved gun regiment.

formations. Searchlight units now consisted of one company (2 horsed 35-cm., 2 motorized 60-cm., 2 motorized 110-cm. projectors) per division, as well as a number of similar units under G.H.Q., and odd formations; further, each technical company or squadron of an infantry or dismounted cavalry regiment included a searchlight squad.

Communication Troops.—Till May 1912 only one combined railway and telegraph regiment existed. This was divided at that date into two. The railway regiment consisted of 3 battalions, depot cadres for personnel, track and for locomotives, and fortress light railway cadres at Przemysl, Cracow and Pola. The companies constituting these battalions were charged in war with the construction, operation and destruction both of standard gauge and of light railways. Consisting at the outset of 30 railway and 4 railway operating companies, this branch had risen at the end of the war to a strength of 39 railway and 32 field railway companies. In occupied territory under Austro-Hungarian control 4 army railway commands were set up (Poland, Serbia, Italy, Rumania) which had at their disposal 8 operating battalions and 28 operating companies. For transport in mountain regions (Alps, Rumania, Albania) there were 40 telpher operating and 9 telpher building companies. The light railway service consisted at the end of the war of 3 locomotive and 21 motor and one horse operating sections, as well as 3 operating sections at Pola. Associated with the railway troops were some bridging detachments provided with iron-bridge equipment.

Lastly should be mentioned *armoured trains*. The first of these, an armoured locomotive, was improvised in 1914 to reconnoitre the enemy during the Galician retreat. Later five trains were built.

The telegraph regiment consisted of 4 battalions, one radio detachment, depot cadre and an administrative unit for stores. This regiment was the parent of all telegraph and telephone units which came into the field, but as with other arms and branches, expansions had to be regularized in the winter of 1917–8. The reorganization in that period reconstituted all telegraph and telephone units uniformly as "telegraph companies," of which at the close of the war there were 159, as well as 65 line construction companies and 25 radio companies. Corps, army and higher headquarters had in all 72 radio posts, worked as 14 administrative groups, and there were 7 fixed stations for long-distance work.

Flying Corps.—Numerically Austria-Hungary was far behind other states in the numbers of her flying troops. Till a few years before the war only captive and free balloons were in use, chiefly in fortresses, and modern aeronautics in Austria were practically followed only as a sport. However, a reorganization took place in 1913 which enabled the army to begin the war with one flying company of 6 machines at G.H.Q. and at each army headquarters, one dirigible balloon company, and depot units. As in other countries, necessity led to rapid developments from this nucleus. By the end of 1916 there were 37 flying companies allotted to the higher headquarters. In 1917 a specialization of flying units according to their missions was begun; thenceforward there were divisional companies for line and artillery work; deep reconnaissance companies, pursuit companies for air fighting, "big machine" companies (bombers), protective companies for escort of divisional machines, and photographic companies for map work. In Nov. 1918 the total of units was 82 flying companies, 32 balloon companies, 12 parks, 9 motor repair units, and 2 construction companies.

Meteorological Service.—This was attached to the flying service, but provided for the requirements of all others as well, and was represented in all formations from divisions upwards.

Motor Transport Troops.—Before the war the use of motor transport for military purposes was limited. For liaison duties between headquarters an Automobile Volunteer Corps and a Motorcycle Volunteer Corps had been formed in Austria and an Automobile Volunteer Corps in Hungary some time before the war. But the first motor troops proper were created in the war itself, when the motorization of the train (ammunition, supplies, medical) and the necessity of regularizing the supply of cars, lorries, parts and fuel imposed this step.

At the outset only a very small proportion of the train was motorized, the lorries coming from private firms by way of requisition.

On formation the "Auto troops" were classified broadly as field troops and home service troops. The first named included by the end of the war 31 group commands and 238 auto columns, 39 ambulance columns, 10 postal columns. The auto troops at home were responsible for the transport of stores and supplies of all kinds to the army and for the training of reënforcements.

Train.—The training of the transport corps (Train) in peace-time was thorough. The vehicles designed for mountain and normal ground proved, however, too heavy for the soft morasses of Galicia and Poland, and for the more forward echelons of transport local vehicles had to be requisitioned. On the other hand the special equipment provided for mountain warfare was excellent.

After the abolition of the regimental organization in 1910 the train consisted of 16 train divs. (one per corps), which in peace carried out all transport duties within the corps and its area, and on mobilization had to provide horses and drivers for all transport formations and for the transport of bridging, postal, medical and other formations. The "division" itself remained at home as a draft and remount producing centre.

The expansion of the army naturally entailed corresponding developments in the Train Corps, which underwent a considerable reorganization in the winter of 1916–7. Simplification of supply procedure and the replacement of heavy military wagons by light vehicles of local types were the main features of this reorganization.

Mountain Warfare Organization.—In Austria-Hungary the organization of mountain troops had been carried further than any other state. At the outbreak of war there existed, as has been mentioned earlier, five mountain regiments of Austrian Landwehr (16 battalions) which were intended as a frontier guard in face of the Italian Alpini. But in 1914 they were used against Russia, Serbia and Montenegro like any other regiment without regard to their special character, and although they in due course returned to the Italian theatre, they were not, as a special arm, augmented during the war, though reënforced by a number of locally raised units.[1] In fact, the generally mountainous nature of the frontiers and war theatres of Austria-Hungary required rather that all troops, and not merely a specialized fraction, should be adaptable to hill warfare.

Thus the troops normally quartered in Dalmatia, Bosnia and Herzegovina, though not essentially mountain units, possessed a special organization in peace-time. The operations unit was the "mountain brigade" which consisted of battalions detached from their regiments, of Bosno-Herzegovinian units, and of mountain artillery. There were 14 such brigades on the south-eastern front at the opening of hostilities, constituting the four divisions of the XV. and XVI. Army Corps. The brigade consisted of 4–6 battalions, sometimes one frontier company, a troop of cavalry and 1–2 batteries, and its engineer and administration services were organized for mountain work. The division had 2 additional mountain batteries, and its headquarter services were partly on the mountain and partly on the normal basis.

As, however, all but one of the theatres of war in which the army was called on to operate were mountainous, this organization was evidently insufficient. Even as early as the winter of 1914–5 there were many improvizations—for example in the Carpathians battle, in which both Austrian and German divisions sent to reënforce von Pflanzer-Baltin had to be reconstituted with mountain transport—and towards the end of the war practically three-quarters of the whole army stood in hill country. Naturally, therefore, a procedure was arrived at whereby any formation on going to a mountainous theatre automatically took on the required form. In the reorganization of 1917–8, indeed, the mountain brigades proper, which meantime had increased in number to 33, became normal infantry brigades, there being no longer any need for them to retain their special character.

Totals of Units in 1914 and 1918.—A general comparison of the organization by units at the beginning of the end of the war summarizes clearly the changes which had taken place. In Aug. 1914 the front line strength of the army in units was about 1,000 battalions, 400 squadrons, and 2,800 mobile guns. In the summer of 1918 the detail is as follows: 262 infantry regiments, also 241 Ersatz battalions, and 170 battalions and 80 companies of volunteers, coast defence troops, etc.; 12 mounted and 48 dismounted cavalry regiments; 132 field artillery regiments, 12 horse artillery regiments, 14 mountain artillery regiments, 66 mountain artillery groups, 14 mortar regiments, 1 gas projector unit, etc.; 60 sapper, river-mining and bridging battalions, etc.; 140 bridging trains; 112 boring sections; 82 flying companies, 32 balloon companies, 4 electro battalions, 240 telegraph companies, 8 battalions and 800 companies of railway troops, 10 searchlight companies and 400 searchlight squads, etc. The sum, as regards front-line strength, totals 1,200 battalions (including adapted cavalry), 72 squadrons, 7,000 mobile guns.

Higher Formations.—At the beginning of the war there were 16 corps headquarters, and 32 divisions of the Common Army, 8 of the K.K. Landwehr and 8 of the Honved, with 9 army and 2 Honved cavalry divisions. On mobilization, 14 "march" brigades, 2 Austrian Landsturm divisions, 10 Austrian and 8 Hungarian Landsturm brigades, 17 Austrian Landsturm territorial brigades, 9 Hungarian Landsturm L. of C. brigades and 5 Austrian Landsturm march brigades, were formed in addition. During the strategic concentration a XVII. Corps was formed, and in Dec. 1914 an XVIII. In Jan. 1915 the combined Corps Krauss in the Balkan theatre (formed Sept. 1914) became the XIX., and for the spring offensive of 1916 against Italy the XX. and XXI were formed. Later in the same year the XXII. and XXIII. came into being, and in 1917 the Szurmay, Hofmann and Hadfy groups became the XXIV., XXV., XXVI. Corps. These 26 corps remained as such to the end of the war. All other temporary groupings, such as cavalry corps, were dissolved when this special reason for their existence ceased. The custom of temporary grouping followed by dissolution prevailed also at the next lower echelon. Many temporary divisions existed especially in the earlier part of the war. But the order of battle was regularized in the winter of 1917–8, in connexion with the internal reconstitution of the division, and finally there were 44 army, 10 Schützen (ex K.K. Landwehr), 12 Honved divisions, and 9 army

[1] Of these the best known were the village riflemen of the Alps; these, known as *Standesschützen*, formed the South Tirolese, Tirolese, Carinthian, Salzburg and Vorarlberg battalions. Volunteer rifle units were raised also in other parts of the Dual Monarchy.

cavalry, 1 Schützen cavalry (Landwehr), and 2 Honved cavalry divisions.

The subdivision of infantry divisions into brigades of two regiments remained unaltered; the cavalry divisions, however, after the reconstitution retained as a rule only one brigade staff. There were thus finally 88 army, 20 Schützen, 22 Honved, 10 Austrian Landsturm, 1 Hungarian Landsturm brigades, and 11 army cavalry, 1 Schützen cavalry and 1 Honved cavalry brigades.

The number of field artillery brigades had grown to 66. The brigade organization of fortress (heavy) artillery had practically disappeared.

Armies.—The foreseen organization of the forces was in six armies, for which six general officers were designated in peace and functioned as inspectors. In Oct. 1914 the Pflanzer-Baltin group was formed in the E. Carpathians; this became the VII. Army later. In Dec. 1914 the V. and VI. Armies in the Balkan theatre were dissolved and reformed as a "Balkan Force."

In May 1915, when Italy came into the war, three new armies were created—a new V., the army group Rohr, and the Tirol Defence Force—under the general command of a commander-in-chief S.W. front. About the same time the III. Army on the Russian front was dissolved, but a new III. Army was formed in the autumn for the operations under Mackensen in Serbia. This III. Army shortly moved to Tirol where, with a new XI. Army and the Tirol Defence Force it constituted a group of armies for the Asiago offensive. Shortly after that the III. Army moved again, this time to the Russian front to aid in meeting Brussilov's offensive; here, with a new XII. Army, it constituted the Archduke Karl's group of armies.

On the entry of Rumania into the war a new I. Army was created. The former I. Army on the Russian front had been dissolved in July 1916.

On the Italian front the Rohr group had meantime become the X. Army, and the Tirol Defence Force was dissolved.

In the winter of 1917, after the Caporetto offensive, a new VI. Army was created to replace the departing German XIV. Army. The V. Army had already become, in the summer of 1917, the Army of the Isonzo; for a time this army was subdivided into the I. and II. Isonzo Armies, forming the Boroevic group of armies, while the X. and XI. Armies constituted the Conrad group of armies.

In the E. nearly all armies were dissolved during 1918, first the I. then the III., IV., VII. The higher command on this side was then shared between the I., IV. and VII. "General Kommandos." The II. Army in Ukraine, however, retained its identity to the Armistice, under the name of K.u.K. Eastern Army.

In Albania, meantime, the Austro-Hungarian forces had been constituted as the Kovess army group. On the breakup of the Bulgarian front in the autumn of 1918 all available forces were constituted as one group of armies under the same general.

The End.—In Nov. 1918 the old Habsburg Empire dissolved in ruin, and with it the famous old army which had maintained its integrity through four years of trial. Its remnants formed nuclei for the national armies of the successor states. Its record was closed, and it passed into the eternity of history. (A-K.; E. J.)

X.—The Turkish Army

At the time of the Balkan War mobilization in 1912, Turkey possessed an army in which the officer corps represented the traditions of the Sultan 'Abdul Hamid. Everything that might make for modern efficiency in war had for 30 years been excluded from the Turkish military curriculum. Ninety-five per cent of the rank and file were illiterate; their main virtues were willingness and endurance. The officers also were in the main untrained; they were drawn either from the stupid and hidebound ranker elements (Alaili) or from the more up-to-date products of the military schools (Mektebli); but even these latter, mostly scions of better-class families, had little sense of accuracy and punctuality in the performance of their duty. There were even general staff officers who could neither read nor write. The Young Turkish movement had the effect of placing more energetic men at the head of the troops, but had also increased military amateurishness to such an extent as to become a positive danger to the army, and to make promotion henceforward dependent, not on efficiency and professional skill, but on political intrigue. The redeeming feature of the army was the quality of the private soldier, and particularly of the Anatolian peasant. No troops in Europe were more steadfast, self-sufficient and patient. The Arabian soldiers were bad, the Kurds useless in face of the enemy and as helpless as children, the Christian and Jewish subjects of Turkey of no military value.

The term of service in Turkey was three years for all arms. Mahmud Shevket Pasha has stated that 240,000 men per year became liable for service; of these some 110,000 to 120,000 were exempted, and of the rest only about 70,000 were actually enrolled. Official returns showed that out of a total pop. of 24,000,000 (of whom at most 15,000,000 were liable for service) men from 20 to 25 years of age numbered 1,080,000, and from 20 to 40 years of age 4,000,000. The *paper* strength of this peace army showed 20,000 officers and 280,000 men. The total war strength of Turkey was reckoned on paper to amount to 24,000 officers, 1,300 officials, and 610,000 men. The forces actually raised in the Balkan War, however, fell far below these figures. An estimate of 450,000 men for the war army would be excessive.

The term of service was made up as follows: three years with the colours (Nizam), up to 29 years of age with the reserve (Ikhtiat), thence up to 38 years of age with the Landwehr (Redif), 39th and 40th years of age with the Landsturm (Mustafiz). In war all classes, including the Mustafiz, were called up. The Ikhtiat brought up the ranks of the Nizam units to war strength; this process usually absorbed them all, as the peace strength of the battalions was only some 200 to 250 men, and their arms in proportion. The Redifs formed separate and complete divisions, organized in their local recruiting areas. Any man liable to service could be released after three months on payment of £50 purchasing-out fine, and was thereafter liable only to service in the older Redif classes. Thus it came about that only the poorer classes of the nation actually served in the army. There was no organization of the officers, N.C.O.'s and military officials not actually with the troops; so that in case of war the only reserve available consisted of the retired officers, of whom, however, as the pension was so small, very few were fit for service. The training of the men was very bad. The model units with their foreign instructors had in the short period of their existence been made to leaven the mass of the army. Constant internal unrest allowed of no continued instruction. The periods of reserve training laid down by law were one month fur the Ikhtiat, and one month every two years for the Redif; but the absence of reserve organization and shortage of money prevented these provisions being carried out. The weakest parts of the Turkish army were the administration and the supply and transport services (provisions, clothing, material and munitions). Peculation was wide-spread, and practically all the administrative personnel were hopelessly idle. The Young Turkish régime brought no improvement. The work of the few German reformers, who under 'Abdul Hamid were never, or practically never, allowed a free hand, proved entirely useless; moreover they were not always very suited to their task, which needed considerable tact if it were to be successfully accomplished.

When the Balkan War broke out Turkey was in the midst of her military reorganization. The greater part of the mass, who had been far too long with the colours, were being sent home; a number of Alaili, who so far had only been mechanically instructed in the rudiments of their duties, had replaced them, so that the whole army organization down to battalions and Redif depots had been suddenly changed. The greatest confusion naturally resulted.

In place of the 7 armies hitherto existing there were formed 14 corps and 5 independent divisions (in Kozani, Yannina [Janina], Scutari, Hejaz and Tripoli). The infantry brigades were done away with, and four divisions were formed, consisting of three infantry regiments, each of three battalions, and a field artillery regiment of two or three detachments. To each corps was allotted a rifle regiment, a cavalry brigade of 10 to 15 squadrons, 6 to 9 heavy batteries, a pioneer battalion, a telegraph company, and a train battalion. Only a few corps, however, actually possessed all these units.

The distribution of the Turkish army in the various theatres of operations in the Balkan War was as follows: Commander-in-chief, Nazim Pasha; Eastern Army (around and east of Adrianople), 'Abdalla Pasha, I., II., III., and IV. Corps and some Redif divs.; Western Army (Kumanovo area), Mahmud Shevket Pasha, V., VI. and VII. Corps and some Redif divs.; Southern Army (Yannina area), 'Ali Riza Pasha, 22nd and 23rd Divs.; against Montenegro (Scutari area), Hasan Riza, later Essad Pasha, 24th Div. and Elbasan Redif Division. The total strength of these forces came to barely 250,000 men. The Anatolian corps and Redif divisions only came into action in Europe after the defeat of the main armies by Bulgaria and Serbia. Soon after their arrival cholera broke out. Though it was known that the VIII. Corps was infected with this disease, none the less it was dispatched to Europe, and the authorities, in order to set public opinion at rest, stated that the epidemic was well in hand. The Eastern Army during its occupation of the Chatalja lines lost in Nov. and Dec. more than 15,000 men, who fell victims to the plague. It may be estimated that of the 400,000 men mobilized by Turkey at least 100,000 were killed, died or were severely wounded (most of these last named may be counted as dead), *i.e.* 25% of the total strength.

The complete military breakdown in the Balkan War forced even the Turks to the conclusion that the time for undertaking serious reforms had come. For this purpose Turkey agreed with Germany that the latter should send her a large military mission under Gen. Liman von Sanders, which arrived in Constantinople in Dec. 1913. Great difficulties were met with in the task of remedying the existing defects in the Turkish military organization and training. The military mission succeeded in effecting certain changes in the organization of the army, and in breathing into it a refreshing and living spirit; but the time which elapsed between its arrival and the outbreak of the World War was too short to carry out the

necessary radical alterations in their entirety. In view of the loss of territory consequent on the Balkan War, it was necessary to remodel the whole peace organization of the army, and distribute it over the diminished area of the empire.

The total peace strength was now on paper 17,000 officers and 250,000 men, with 15,000 guns and 430 machine-guns; actually these numbers were never even approached. To each division was allotted a definite recruiting area. Area commanders were established after the German model, but did not effectively get to work prior to the World War. The organization of Redif divisions was also taken in hand; the personnel not actually called up for peace service were to form these units, which were to be utilized in time of war to complete the first line units to full strength. Great importance was rightly attached to the institution of new military schools, the inspection of which was undertaken by Liman von Sanders after he had handed over command of the I. Corps. A new Army Act became law on May 12 1914, but its provisions were never strictly enforced. Its principal clauses were: Every Turk, except for the suite of the Sultan's family, was liable to service from the age of 18. The period of service commenced on the March 1 next following the attainment of the age of 20, and extended over 25 years for infantry and train, for the other arms 20 years, and for the navy 17 years. The period of active service was in each of the above cases two, three and five years; students were allowed an abridged term; physically unfit men were liable to a special tax in lieu of service. Purchasing out was allowed after five months' service at the rate of £50 Turkish; men thus liberated were transferred to the reserve and escaped all further liability for military duty in peace-time. Christian subjects of the empire were excluded from the ranks of the fighting troops. The War Office was reorganized from top to bottom. The great general staff was also entirely remodelled, German officers being placed at the head of the more important branches, such as those concerned with training, mobilization and intelligence.

Little or nothing could be done in the short space of time between the Balkan and European wars in the direction of rearming the army, so that the armament in the World War remained much as in the Balkan War. The infantry weapon was the 7·65-mm. Mauser repeating rifle, but older models were still partly in use. The field artillery had the 7·5-cm. Krupp field gun with recoil buffer and shield, 1904, 1909 and 1911 models; in addition there were a few old 8·7-cm. German field guns. The mountain guns in use were the 7·5-cm. Krupp 1905 model; the Schneider 7·5-cm., which was somewhat more modern, was also in use. The heavy artillery had a number of guns of various patterns, many of which were fairly antiquated; only a few modern 15-cm. Krupp howitzers and Schneider-Creusot howitzers were available for use. Several howitzer batteries were still using smooth-bore guns, which were as good as useless on account of their short range. The fortress artillery was completely out of date, consisting as it did mainly of guns of 1880 and 1890. Moreover, lack of money prevented any steps being taken to bring the land fortresses up to date.

The Turkish forces were mobilized in the first days of Aug. 1914, but there was only a month of armed neutrality in which to prepare for war. This respite was used by Germany to equip Turkey with practically everything necessary for carrying on hostilities. Despite this German assistance the mobilization met with great difficulties. A Turkish War Office return in the summer of 1917 (which must however be accepted with caution) gave 1,478,176 as the number of recruits called up from Aug. 1914 to March 1915, 1,014,824 from March 1915 to March 1916, and 332,000 from March 1916 to March 1917. Figures as to enrolments from this latter date onwards are completely valueless. The grand total of all who served in the Turkish army from 1914 to 1918 amounted on this showing to 3,000,000 men. If we take into consideration the facts that many of these were counted twice or three times over it may be regarded as approximating to accuracy to reduce this total to 2,000,000, of whom some 750,000 deserted and 500,000 were killed or invalided out of the service in the course of the war. It is of interest to note that the officials in Turkey who were not affected by the military law, always reckoned all men called up—that is, rounded up by the police—as being of military age whether they were really so or not. Thus it happened that many young men were exempted as not coming within the age limit of 48, while unfortunates of 50 and boys of 15 were given as being 20 or 30 years old, and therefore of military age.

The establishment of officers in the Turkish army reached its maximum of 30,429 in the spring of 1917; the army, however, was at its greatest strength of 1,295,621 in the previous spring. Despite great efforts and reckless use of all possible man-power resources, this total could not be maintained in 1917; in the spring of that year only 1,200,344 men were present, and from that date on the total rapidly declined.

The organization of the supreme army command was also the work of the German military mission. This was in the hands of headquarters in Constantinople. The Sultan of course held the titular post of commander-in-chief, Enver Pasha being vice-commander-in-chief. As the latter gradually assumed the political dictatorship of Turkey, divergence of views between the civil and military authorities ceased to exist.

In the first days of mobilization in Aug. 1914 the following formations and organizations were in being: 4 army inspections, 13 general commands, 38 divisional staffs, 305 battalions infantry, 64 machine-gun companies, 115 squadrons, 211 field batteries, 124 heavy and fortress batteries, 47 pioneer companies, 4 fortress pioneer companies, 36 fortress construction companies, 42 searchlight troops (equipped with one searchlight each), 21 telegraph companies, 1 wireless telegraph company, 10 railway companies, 135 reserve squadrons, 17 service companies, 17 works troops and 51 train companies. The reserve squadrons were formed from the so-called Kurdish or Hamidic cavalry, and comprised 4 reserve cavalry divisions. They were quite untrained and of no military value. They had all the characteristics of independent nomads, and were imbued with the bitterest ill-feeling against the Armenians.

The war organization provided at first for three and in Sept. 1914 for four armies. The original armies were: I. Army, Gen. Liman von Sanders, I., II., III., IV. and VI. Corps, one cavalry brigade and one battery heavy howitzers; II. Army, Jemal Pasha, V. Corps and (from Sept. 6 1914) VI. Corps, cavalry as for the other armies, and all available heavy artillery; III. Army, Hasan 'Izzet Pasha, X. and XI. Corps; IV. Army, Zeki Pasha (later Jemal), VIII. and XII. Corps. The other troops of the peace army remained for the time being unorganized in armies. But even with these few armies it was not possible to bring the troops up to full war strength with the reserves available; some companies were barely 100 strong even in Jan. 1915. During the later stages of the war Enver's policy of limiting the formations to a few well-organized corps and armies was given up; new formations were constantly being ordered, and old ones broken up or remodelled. For these the available man-power, armament and equipment were insufficient, so that the whole army became completely disorganized.

During the war the number of the armies was increased to nine. The army leaders were continually being given other troops, and having to give up divisions and corps, so that their armies were constantly growing smaller. Thus the I. Army, which in 1914 was over 200,000 strong, had sunk by 1917 to about 3,000 men, and the II. Army by 1918 to 5,000 men, and in 1918 there were in Palestine three Turkish armies, none of which were stronger than an English infantry division. All the armies, corps and divisions, however, still kept up their enormous staffs.

The number of officers in the German military mission increased in 1916 to 200, in 1917 to 800; a large number of other ranks, mostly of the technical services, must be added. Of complete German units the personnel of a few batteries at the Dardanelles and the crews of the "Goeben" and "Breslau" fought with the Turkish army. Enver shrank from employing larger units, and in principle stood out against it. Only the so-called "Yildekim" (known to the Germans as "F") Group consisted entirely of German troops. (F. C. E.)

ARMY MEDICAL SERVICE (United Kingdom).—The British Army Medical Service never had such a task imposed on it as during the World War, from which it emerged with its organization tested by fire. Its duties cover the care of the sick and wounded of the military forces, the preservation of their health, the supply of medical and surgical material, the maintenance and administration of military hospitals and the command of patients in them, the medical examination of recruits and invaliding of men unfit for further service, the education and training of its own personnel, and the strategical and tactical employment of a variety of medical units concerned with the collection, evacuation and distribution of casualties in war.

Until 1873 the functions of an Army Medical Service had been carried out by a regimental system under which medical officers belonged to and wore the uniform of the regiments to which they were gazetted, and under which many of the sick and wounded were cared for in regimental hospitals. Soldiers enlisted in the combatant ranks were trained in hospital duties and formed a Medical Staff Corps, but they were not under the command of the medical officers. In 1861 "Medical Staff Corps" was changed to "Army Hospital Corps," but the pay and discipline of the men were directly under the department of the purveyor-in-chief, and medical officers had no military position until 1869, when the director-general for the first time was attached to the military department of the War Office on the recommendation of a committee presided over by Lord Northbrook. In 1878 the personnel of the Army Hospital Corps was recruited by direct enlistment. In 1883 a committee under Lord Morley, after the Egyptian War, recommended that the Army Hospital Corps and the officers of the Army Medical Department should be merged into a "Royal Medical Corps," but this recommendation was not adopted at the time. A compromise was made by forming the officers into a body called the "Medical Staff" and the men into a corps called the "Medical Staff Corps," their

original name. At the same time the officers of the Medical Staff took complete command over the personnel of the Medical Staff Corps, and their uniform was assimilated to that of the latter. Eventually, after considerable agitation on the part of the medical profession, Lord Lansdowne, then Secretary of State for War, announced, at a banquet given by the Lord Mayor of London on May 4 1898 to the medical profession, that the Medical Staff and the Medical Staff Corps in future would be consolidated into one corps, namely the Royal Army Medical Corps (R.A.M.C.), with military ranks and titles from private to colonel similar to those of other branches of the army. The ranks above colonel, however, retained the title of surgeon-general until 1918, when this title was abolished and replaced by that of major-general or lieutenant-general.

Peace Organization

Administration.—The director-general of the Army Medical Service is the administrative head. He has the rank of lieutenant-general. His office is a branch of the adjutant-general's department at the War Office. He is not, however, a member of the Army Council, but may be required to attend council meetings when his advice is desired on any special subject. His staff consists of a deputy director-general, who is a major-general, eight officers of the rank of colonel, lieutenant-colonel or major (some of whom hold temporary appointments only consequent on the World War) as assistant and deputy assistant directors-general, and colonels-on-the-staff or major generals as directors of hygiene and pathology. The directors of hygiene and pathology have deputy directors, assistant directors and deputy-assistant directors of hygiene and pathology as assistants in their directorates. The administration of the Queen Alexandra's Imperial Military Nursing Service (Q.A.I.M.N.S.) also forms a branch of the director-general's office under the matron-in-chief assisted by two principal matrons and a nursing sister. In 1921 an inspector of dental services was added to the director-general's staff on the formation of an Army Dental Corps, with the rank of lieutenant-colonel.

The director-general's administration is assisted by an inspector of medical services, who is either a colonel or major-general of the Army Medical Service. He visits all stations at home and overseas with a view to maintaining a uniform standard of training and efficiency. He reports to the adjutant-general.

In all commands at home and overseas the director-general is represented by deputy-directors and assistant-directors of medical services. In some of the smaller garrisons the senior executive medical officer acts in an administrative capacity without being graded as a deputy or assistant director. The staff of these administrative offices varies according to the size and importance of the command or the conditions under which troops are serving. Thus in the small garrisons in the tropics where medical research is of importance there is a deputy assistant director of hygiene and pathology, although the administration may be in the hands of a senior medical officer only. In India there is a special administration for the Army Medical and Indian Medical Service. Officers of the latter, when employed on military duties, are under the administration of a director of medical services, who is a major-general or lieutenant-general of the Army Medical Service, but the administrative appointments of the subordinate military commands in India may be held either by Army Medical or Indian Medical deputy directors and assistant directors. In war establishments there is a director of medical services in the headquarters of each army, a deputy director with each corps and an assistant director with each division. On their staffs are representatives of the directors of hygiene and pathology and ot[illegible]nts.

Advisory Boards.—Conne[illegible] Medical administration there are several advisory [illegible] committees composed of military and civil members. [illegible] Advisory Board advises on general professional [illegible] is presided over by the director-general and its members [illegible] consulting physicians, two consulting surgeons, the medical [illegible] of the India Office and an officer of the Royal Army Medical Corps. An Army Hygiene Advisory Committee is presided [illegible] by the director of hygiene. Its members include an officer [illegible] Royal Engineers (R.E.) and of the Royal Army Service Corps (R.A.S.C.), and military and civil sanitary experts. An Army Pathology Advisory Committee under the director of pathology is similarly composed of military and civil pathologists of eminence who deal with technical questions connected with research into the causes of disease. Queen Alexandra's Army Nursing Board, of which Queen Alexandra is president and the director-general chairman, is composed of the matrons-in-chief of Q.A.I.M.N.S. and Territorial Force Nursing Service, of matrons of some of the large civil hospitals and of ladies nominated by the president. There is also a Technical Advisory Committee on Voluntary Aid under the director-general. It is composed of representatives of the War Office, British Red Cross Society, Scottish Branch of the Red Cross Society, the council of County Territorial Force Associations, and the St. John and St. Andrew's Ambulance Associations. These boards and committees meet at the War Office.

Personnel.—The personnel of the Army Medical Service consists of officers, warrant officers, non-commissioned officers and men of the R.A.M.C. regular, special reserve, and territorial force, and of the Army Dental Corps, together with the affiliated nursing services of the regular army and territorial force, and the voluntary organizations recognized by the British Government under Article 10 of the Geneva Convention of 1906. The ranks of officers and men are the same as for other branches of the service. Officers and other ranks of the regular R.A.M.C. are under an obligation to serve in all parts of the world in peace or war: but only the officers serve in India, where the duties of subordinate ranks are carried out by a special Indian establishment consisting of an Indian Subordinate Medical Service, an Army Hospital Corps and an Army Bearer Corps. The members of the last two are natives of India. The members of the Indian Subordinate Medical Service are Indian-born British or natives of India educated in Indian medical schools. The higher grades rank as commissioned officers and the lower as warrant officers. The special reserve is organized on a militia basis and serves on embodiment under the same conditions as the regular Royal Army Medical Corps. The Territorial Force R.A.M.C. is organized for war purposes only. It has a general list of officers for service with regimental and medical units, a special list for territorial force general hospitals; and another for sanitary services. The rank and file of the regular R.A.M.C. are formed into companies, of which in 1921 there were 35, in addition to four depot companies. Eleven of the companies had their headquarters in overseas garrisons. Both at home and overseas the headquarters of R.A.M.C. companies are at one or other of the larger military hospitals. They provide detachments for smaller hospitals and general duty. The number in each company varies in accordance with local requirements. The normal peace establishment of the regular R.A.M.C. on the active list is approximately 1,100 officers and 3,800 other ranks, but this is greatly expanded in time of war by calling up reserves of every description. During the World War it had expanded to some 15,000 officers and 170,000 other ranks, in the case of officers chiefly by granting temporary commissions to members of the civil profession.

Training.—The depot for training the regular R.A.M.C. is at Aldershot. Territorial Force R.A.M.C. are trained in a school of instruction in each of 12 territorial divisions by officers of the regular R.A.M.C., who act as adjutants of the schools. There is a R.A.M. College in London, where officers of the regular R.A.M.C., both on joining and before promotion to major, undergo a course of instruction in military hygiene, tropical diseases and other professional subjects; training in field duties is carried out in the form of staff tours, camps of instruction and medical manœuvres. Training in sanitation is carried out in an army school of hygiene at Aldershot and in schools of hygiene established in commands.

Military Hospitals.—Military hospitals are established in all commands at home and abroad. They vary in size from large general hospitals, such as the Royal Victoria hospital at Netley with over 1,000 beds, to small depot hospitals and detention wards in outlying posts. The number of beds normally maintained in peace-time in the United Kingdom is approximately seven thousand. In the World War this number expanded to more than 364,000; or, including beds in all theatres of war, to over 640,000.

Medical Stores.—An Army Medical Store is maintained at Woolwich for the supply of medical and surgical material and equipment to all garrisons at home and overseas, with the exception of India, which has its own stores. Supplies are obtained by contract from manufacturing firms. They are distributed through the central stores at Woolwich.

War Organization

The organization of the Army Medical Service for war does not come into existence until mobilization is ordered. Medical units, the equipment for which is maintained in mobilization stores, are then brought into being by the assembly of personnel, material and transport at places of mobilization assigned to each unit. Three zones of medical work are recognized: The collecting zone, the evacuating zone, and the distributing zone. In these zones there are medical services for the collection, transport and treatment of sick and wounded, for the supply of medical

and surgical stores, and for sanitary duties. Sick and wounded are collected in the first instance by a regimental medical service and passed from it to the field ambulances of the divisions. They are cleared from the divisions by motor ambulance convoys, which convey them to casualty clearing stations, whence they are passed down the lines of communication by rail, canal or road to the permanent hospital bases, and from there by sea-going hospital ships to the hospitals in the United Kingdom. The collecting zone may be regarded, therefore, as the area of work back to the casualty clearing stations; the evacuating zone as the lines of communication down to the sea bases or to the United Kingdom, and the distributing zone as the area of the hospital bases and the home territory.

The Regimental Medical Service.—Each regiment of cavalry, battalion of infantry, brigade of artillery, ammunition column, squadron or bridging train of engineers and certain supply trains has an officer of the R.A.M.C. attached to it, together with a small detachment of R.A.M.C. other ranks for technical charge of water carts and water supplies. Sixteen men of the regiment are placed under him during battle as stretcher-bearers; and a non-commissioned officer and eight men, trained in sanitary duties, also work under him. Wounded are collected to a regimental aid post, which is established by the medical officer in a shelter or protected spot near regimental headquarters.

Field Ambulances.—There are two forms of ambulances, the cavalry field ambulance for cavalry divisions and the field ambulance for divisions. They differed considerably in organization and transport before the World War, but since then the chief difference is in their transport. A cavalry division has a cavalry field ambulance for each brigade of which it is composed. Thus a cavalry division of four cavalry brigades would have four cavalry field ambulances. Divisions have three field ambulances each. Both a cavalry field ambulance and a field ambulance are composed of a bearer division and a tent division, and are organized in two sections, each section being formed of half the bearer and half the tent division. In the bearer division there are 18 stretcher detachments. They bring wounded back from the regimental aid posts to an advanced dressing station formed by one of the tent sub-divisions at a point to which wheeled transport can come up. Wounded are conveyed from the advanced dressing station to a main dressing station formed some distance back by the remainder of the field ambulance or by other field ambulances where there is less exposure to enemy fire than at the advanced dressing station. Formerly both classes of ambulance had each 10 horse-drawn ambulance wagons, six of which in cavalry field ambulances were light wagons, the remaining four being heavy wagons of the same type as the 10 wagons of the field ambulance. Motor ambulance cars replaced a proportion of the horse-drawn wagons after the British Expeditionary Force moved from the Aisne to the Flanders front in 1914. The ambulance transport of the cavalry field ambulance now consists of four motor ambulance cars and six light horse-drawn ambulance wagons; that of the field ambulance is seven motor ambulance cars and two heavy horse-drawn ambulance wagons. They are employed in battle in carrying wounded from the advanced to the main dressing station, but may go forward in advance of the former where it is possible to do so. Their carrying capacity is two lying or eight sitting in the light wagon or light ambulance car, and four lying or 12 sitting in the heavy wagon or motor ambulance car. Field ambulances are divisional troops and come under the command of the assistant director of medical services of the division.

Motor Ambulance Convoys.—The first motor ambulance convoy used by the British in war was organized at the end of Sept. 1914 during the battle of the Aisne. It was formed of ambulance cars sent to France by the War Office early in Sept. and was rapidly followed by similar convoys, some of which were provided by voluntary organizations. Previously the system by which sick and wounded were brought from the field ambulances to railhead was to load them in the lorries of the supply columns returning empty to refill. But the system broke down early in the World War partly because this form of transport subjected the wounded to serious discomfort and jolting, and partly because the requirements of supply services and medical services were in conflict with one another. A motor ambulance convoy consists of 50 motor ambulance cars; it is under the command of an officer R.A.M.C. with R.A.M.C. personnel for medical duties, and a R.A.S.C. personnel under an officer R.A.S.C., as drivers and mechanics. The number of these convoys allotted to an army is usually in the proportion of one for each army corps of which the army is composed, and one as an army reserve. They are normally army troops under the control of the director of medical services, who may, however, place them at the disposal of deputy-directors of army corps. Their function is to clear the field ambulance main dressing station of sick and wounded to casualty clearing stations at or near railheads, and to perform all other ambulance transport duties by road not carried out by the transport of field ambulances. In the event of railway transport breaking down or proving insufficient to relieve congestion of sick and wounded in the front areas, motor ambulance convoys may be employed for conveying sick and wounded to hospitals at the base.

Casualty Clearing Stations.—These are medical units which form the link between the collecting and evacuating zones, or between the divisions of the field army and lines of communication. Their function is to receive the sick and wounded from the divisional field ambulances. Sick and wounded likely to be fit for duty after a short period of treatment are retained, as are also those too seriously ill for further transport. The remaining sick and wounded, after receiving temporary medical and surgical treatment, are evacuated as rapidly as circumstances and railway transport permit to the hospitals at the base. Casualty clearing stations are consequently organized with a convalescent or lightly wounded section, a hospital section, and an evacuating section. The number of casualty clearing stations allotted to an army is in the proportion of one for each division, but they are essentially strategical units and are army troops, the director of medical services being responsible for placing them where they may best receive and evacuate the number of wounded anticipated in battle. They are mobilized with personnel and equipment for the care of 200 casualties at a time, but are capable of expansion to any extent in the field from local resources or by bringing up additional equipment and stores from the base, whenever the nature of the operations admits of this being done. The organization of casualty clearing stations, therefore, depends very much on the nature of the military operations. The general principle upon which it is based is the mobilization of a light mobile unit in the first instance capable of following up an advancing army with sufficient equipment and shelter for surgical work at an advanced operating centre, and adding to it more extensive accommodation and equipment whenever circumstances permit. In its original composition a casualty clearing station had no transport of its own. During the World War three 3-ton lorries were allotted to it. It was customary to group them in twos or threes in the same locality. The lorries of a group of three casualty clearing stations would thus be sufficient to carry forward the advanced operating section of one of the three, and then return for the others. The weight of the original equipment, including marquees for 200 patients, was 21 tons, so that the nine lorries were capable of carrying this load. The heavier equipment and more extensive accommodation added during stationary warfare required 50 to 60 lorries for moving a casualty clearing station by road, or a complete train by rail. Casualty clearing stations are allotted two 3-ton motor lorries each.

Ambulance Trains.—The evacuation of wounded by railway is effected by specially constructed or by improvised ambulance trains. The former are composed of ambulance coaches with through communication and accommodation varying from 300 lying down to 600 sitting up. They are commanded by an officer of the R.A.M.C. and are administered by the director of medical services on the lines of communication, whose staff regulate their journeys in association with the railway transport staff and in accordance with the demands of the field army. They are mobilized as a rule in the proportion of one for each division in the field, but their number depends on the length of the journeys from front to base and the time taken to return. Improvised ambulance trains are made up of passenger coaches or goods vans specially fitted for carrying sick and wounded. The ambulance trains were of this kind at the beginning of the World War, and were organized to carry 396 lying down on stretchers placed on special frames constructed to carry three stretchers each. Four frames were placed in each of 33 goods vans. Improvised trains subsequently were used in emergency only and were usually in the form of passenger coaches for transport of patients sitting up. When these improvised trains are used rest and refreshment stations are opened at intermediate halting places for supplying food and comforts and for removing patients unfit to continue the journey and transferring them to local hospitals. Rest stations for attending to patients pending their removal to hospital are also opened at stations where all classes of ambulance trains unload. They are formed by detachments from hospital units or by voluntary aid.

Ambulance Flotillas.—Although ambulance flotillas of river steamers or barges are war establishment units of continental armies, they are not definitely organized units of the British Army. They were formed, however, in 1914–8 for use on the canals in the north of France, and were composed of barges specially equipped as hospital wards and towed by steam tugs. Each barge had 30 beds, kitchen and stores, and accommodation for a staff of one medical officer, two nursing sisters and nine R.A.M.C. orderlies. Six barges formed a flotilla, and four flotillas were organized. They brought seriously wounded from casualty clearing stations to such hospitals on the lines of communication as were on or near a canal.

Hospital Ships.—Passenger or other ocean-going ships are chartered in time of war and fitted out as hospital ships for evacuating sick and wounded from the sea bases of a theatre of war to the United Kingdom. Their number and carrying capacity depend on the nature of the campaign, but the most suitable are those which are neither too large nor too small. A ship carrying 600 to 800 patients in cots was regarded as the best during the World War.

Hospitals are of two kinds, general and stationary. The former are fully equipped for all kinds of medical or surgical work. They are organized for 520 or 1,040 hospital beds, the smaller in the proportion of two and the larger in the proportion of one for every division in the

field. They are situated at or near the sea bases but may be established in greater or smaller hospital centres elsewhere on the lines of communication. The stationary hospitals are smaller and less fully equipped than the general hospitals and are organized for 200 or 400 beds. They are intended to act as local hospitals for the sick of large camps or other posts on the lines of communication, or as hospitals for special purposes such as the reception and treatment of infectious diseases. They are mobilized in the same proportion as general hospitals. In the United Kingdom the Territorial Force R.A.M.C. mobilize 24 general hospitals in time of war, each of 520 beds.

Convalescent Depots.—These form large camps at the bases or elsewhere where convalescents on discharge from hospital are made physically fit to return to duty by convalescent treatment and graduated physical training. There is no fixed limit to their numbers or size. During the World War a convalescent depot could accommodate from 1,000 to 5,000 men.

Medical and Surgical Supplies in War.—Two kinds of units are organized for maintaining and distributing medical and surgical supplies, the base depots of medical stores and the advanced depots. They are in charge of quartermasters of the R.A.M.C. The base depots receive their supplies through the Army Medical Stores at Woolwich. They supply the hospitals and medical services at the base and on the lines of communication, and are placed as a rule at the sea bases. Originally the proportion was one for every two divisions, but there was no fixed proportion during the World War. As a rule there was one at each sea base or advanced base. Advanced depots of medical stores are army troops under the control of the director of medical services of the army, and are allotted in the proportion of one for each army corps. They are replenished from the base depots and supply the casualty clearing stations, the divisional medical units and other medical services of the field army.

Sanitary Organization in War.—In addition to the sanitary detachment of each regimental unit, a sanitary section of one officer and 25 men is mobilized with each division and for each base. Sanitary squads of one non-commissioned officer and four men are also mobilized for each railhead or railway post on the lines of communication. The personnel of sanitary sections and squads act as sanitary inspectors, supervise the construction of sanitary requirements in camps and billets, and maintain sanitary establishments.

Mobile Laboratories.—For special work in the field four classes of mobile laboratories are organized. Mobile hygiene laboratories for chemical analysis of water and food supplies and for other hygienic investigations are allotted in the proportion of one to each army. Mobile bacteriological laboratories for medical and surgical bacteriological investigation are allotted in the proportion of two to each army. A mobile X-ray laboratory and a mobile dental unit, in the proportion of one of each to an army, are attached to one of the casualty clearing stations. All these laboratories are constructed on motor chassis and can be placed in any area as required.

Nursing Services in War.—Members of the nursing services are employed in all the general and stationary hospitals, in ambulance trains and flotillas, hospital ships and casualty clearing stations.

Voluntary Organization in War.—Voluntary aid detachments of men and women are organized under County Territorial Force Associations by county directors of the British Red Cross Society or St. John Ambulance Association. They have a definite composition and are registered at the War Office. On mobilization they undertake the opening and staffing of auxiliary hospitals throughout the United Kingdom and the local transport of patients who are being distributed to hospitals in the United Kingdom. Members of women's Voluntary Aid Detachments (V.A.D.) may also be employed in nursing duties in military hospitals. In theatres of war the chief function of voluntary aid organizations is to maintain stores for supplementing hospital equipment and supplies by articles which may add to their comfort and appearance, and by distributing gifts. Medical units offered by voluntary services or private individuals are not recognized unless they are organized on the same lines as corresponding regular units and under the command of officers of the R.A.M.C. In addition to the voluntary aid detachments, the St. John Ambulance Brigade and the St. Andrew's Ambulance Association maintain a home hospital reserve, the personnel of which takes the place of the regular R.A.M.C. in the military hospitals in the United Kingdom when the latter are mobilized to form the medical units of the war establishments. At the beginning of the war in 1914 the St. John Ambulance Brigade had ready a home hospital reserve of 2,200 men and the St. Andrew's Ambulance Association 113, but these numbers increased so rapidly that by the end of 1915 over 15,000 of the St. John Ambulance Brigade were serving in the military hospitals in Great Britain. (W. G. MA.)

UNITED STATES

Functions.—By Army Regulations the Medical Department in 1910 was charged with the following duties: Investigating the sanitary conditions of the army and making recommendations with reference thereto; advising with regard to the location of permanent stations, the selection and purification of water supplies, and the disposal of wastes, caring for the sick and wounded; making physical examinations of officers and enlisted men; managing military hospitals; recruiting, instructing and controlling the enlisted force of the Medical Department and the Nurse Corps; and furnishing all medical and hospital supplies, except for public animals. In 1921 these functions persisted.

COMPOSITION

Medical Department.—In 1911 the Medical Department comprised the Medical Corps, Medical Reserve Corps, Dental Corps, Hospital Corps (male), and Nurse Corps (female), to which could be added contract surgeons and other civilians. The National Defense Act of 1916 provided that the Department should consist of "one surgeon-general, . . . who shall be chief of said department, a Medical Corps, a Medical Reserve Corps, . . . a Dental Corps, a Veterinary Corps, an Enlisted Force, the Nurse Corps, and contract surgeons . . ." Subject to the appointment of great numbers of officers in temporary grades up to and including that of major-general, as authorized by war legislation, this Act covered the organization of the medical service during the World War, with the exception that a new temporary body was formed which was known as the Sanitary Corps and consisted of officers and enlisted men, not graduates in medicine, who possessed knowledge or experience of value to the Medical Department. The Act approved June 4 1920 stipulated that the surgeon-general should have the rank of major-general and should have two assistants with the rank of brigadier-general; it added a new branch, the Medical Administrative Corps; under this Act the enlisted strength of the Medical Department could not exceed 5% of the actual commissioned and enlisted strength of the army; the number of officers in the Medical Corps was fixed at 6·5 for every 1,000 of "authorized" (virtually actual) enlisted strength of the regular army.

As provided by Act of April 23 1908, the *Medical Corps* of the army consisted of one surgeon-general with rank of brigadier-general, 14 colonels, 24 lieutenant-colonels, 105 majors and 300 captains or first lieutenants, advancement being by seniority except in the case of lieutenants, who were promoted after three years' service. The scheme for promotion was modified by the Act approved June 4 1920, to provide that officers of the Dental and Medical Corps should be promoted to the grade of captain after three years' service, to the grade of major after 12 years' service, to the grade of lieutenant-colonel after 20 years' service, and to the grade of colonel after 26 years' service, all subject to the satisfactory passing of the required examinations. On Oct. 1 1921 there were 43 colonels, 87 lieutenant-colonels, 483 majors, 474 captains, and 52 first lieutenants.

Beginning with 1901 the Medical Department employed civilian dentists under contract. The Act of March 3 1911 established a *Dental Corps*, consisting of lieutenants in the proportion of one to each 1,000 of actual enlisted strength of the army, but in no event to exceed 60. By an Act approved Oct. 6 1917 the Corps was made to consist of officers of the same grades and proportionate distribution of grades as were then, or as might thereafter, be provided by law for the Medical Corps. On Oct. 1 1921, there were in the Dental Corps eight colonels, 15 lieutenant-colonels, 62 majors, 132 captains and 25 first lieutenants. The *Veterinary Corps* was established by the National Defense Act and took over the veterinarians formerly assigned to mounted regiments and to the Quartermaster Department. On Oct. 1 1921 there were in the Veterinary Corps four colonels, six lieutenant-colonels, 17 majors, 25 captains, 97 first lieutenants and six second lieutenants. The *Medical Reserve Corps* was established by Act of April 23 1908 for the purpose of securing a supply of medical officers available in emergency. The National Defense Act abolished the Medical Reserve Corps, as such, and established an Officers' Reserve Corps, with sections corresponding to the various arms, staff corps and departments of the regular army. Under this law a medical section of the Officers' Reserve Corps, containing approximately 1,256 physicians, existed at the outbreak of the World War. On Oct. 14 1921 there were 5,816 officers enrolled in the medical section of the Officers' Reserve Corps, 3,747 in the dental section, 390 in the veterinary section, 264 in the sanitary section, and 491 in the medical administrative section. A Hospital Corps, composed of hospital stewards and privates, was established by Act of March 1 1887, which directed that all necessary hospital services in garrison, camp or field, including ambulance service, should be performed by members of this corps, which was permanently attached to the Medical Department. The National Defense Act abolished the designation "Hospital Corps" and substituted therefor an *Enlisted Force*, consisting of non-commissioned officers, privates first class, and privates. The U.S. Army *Nurse Corps* (female) came into existence in 1901. No appreciable change in its organization was made until the Act of June 4 1920, when the members of the Nurse Corps were given relative rank, the superintendent having that of major, the assistant superintendents that of captain, chief nurses that of first lieutenant, and head nurses and nurses that of second lieutenant. In respect of matters within the line of their duties, nurses were given authority, in and about military hospitals, next after officers of the Medical Department. Nurses in 1921 continued to be employed under contract for a period of three years, and did not receive the pay of their relative rank. The *Medical*

Administrative Corps was established by the Act approved June 4 1920. Appointees therein must have had enlisted service in the Medical Department. These officers act in the capacity of adjutants, mess officers, registrars, property officers, commanders of detachments, and the like, in medico-military units, thereby relieving medical officers of the necessity of performing these essential but non-professional duties.

National Guard.—The organized militia, known as the National Guard, possesses a medical department consisting of a medical corps, dental corps, veterinary corps and enlisted force, conforming in organization, discipline and equipment to like units of the Medical Department of the regular army. The personnel, known collectively as sanitary troops, is divided into three groups: (*a*) those assigned to combatant units; (*b*) those organized into sanitary units such as medical regiments, hospital companies and ambulance companies; and (*c*) those belonging to state staff corps and departments.

PEACE-TIME ORGANIZATION

Surgeon-General's Office.—Whether in peace or war, the surgeon-general's office in Washington is one of the coördinate bureaus of the War Department which function under the Secretary of War through the intermediate channel of the chief-of-staff. The surgeon-general advises the War Department in matters relating to his bureau, coordinates all technical activities of the Medical Department through corps area or department surgeons, originates medical policies, compiles medical statistics, distributes personnel to the corps areas and geographical departments, and directly controls all matters relating to the purchase of supplies and the expenditure of appropriations for construction and repair of hospitals and employment of civilians. These functions did not change materially in character between 1910 and 1921 but the work expanded greatly; then the duties were divided between four divisions:—Personnel, Supply, Sanitation, and Museum and Library; the organization on Oct. 1 1921 included the following eleven divisions, each being staffed with one or more officers specially selected because of their knowledge of the subjects handled: Administrative; Coördination, Organization and Equipment; Dental; Finance and Supply; Hospital; Library; Personnel; Sanitation; Statistical; Training; Veterinary.

Aviation Service.—Detailed administration of Medical Department matters relating to aviation is handled by a medical officer attached to the staff of the chief of the air service.

Department and Corps Area Surgeons.—The continental United States is divided for administrative purposes into nine "corps areas," and the outlying possessions into three departments (Hawaiian, Philippine, and Panama Canal). A department or corps-area surgeon, as one of the staff of the commanding general of each department or corps area, presides over the medical activities therein.

Station Personnel.—At all military stations, other than general hospitals, medical officers and a suitable detachment of enlisted men of the Medical Department are assigned to care for the troops and to administer the station hospital, which usually provides beds for at least 3% of the forces. If the command is part of a tactical unit some or all of these medical officers and enlisted men are nominally attached to the combatant troops in preparation for active service.

General Hospitals.—Large institutions, known as "general hospitals," are maintained (*a*) to afford better facilities than can be provided at station hospitals for the observation and treatment of obscure, complicated and serious cases, (*b*) to instruct and train junior officers, nurses and enlisted men, and (*c*) to furnish a nucleus for expansion in time of war. In 1910 there were four such hospitals in the United States army, which number in 1921 had been increased to six.

Education, Training and Investigation.—The Army Medical School, Washington, D.C., was established in 1893 with the object of training students in the duties which pertain to the Medical Department. The student body consists of officers of the Medical Corps, the Medical Reserve Corps and the National Guard, and of enlisted men in the Medical Department. From 1910 to 1919 the regular course covered about eight months, but it was shortened and instruction in the non-medical features of a complete medico-military curriculum transferred to the Medical Field Service School, established in 1920 at Carlisle, Pa.

WAR-TIME ORGANIZATION

Object of the Medical Department in War.—The objects of Medical Department administration in war are: First, the preservation of the strength of the army in the field by (*a*) the institution of requisite sanitary measures for preventing avoidable sickness; (*b*) the retention of effectives at the front; and (*c*) the prompt succour of wounded on the battlefield and their removal to the rear, thus preventing the unnecessary withdrawal of combatants from the firing line to accompany them. Second, the care and treatment of the sick and injured in the zone of the advance, on the line of communications, and in the home territory. Third, the promotion of general *moral* among the troops through the knowledge that efficient medical and surgical attention is immediately available.

Voluntary Aid and the Red Cross.—Organized voluntary aid may be utilized to supplement the resources and assist the personnel of the Medical Department only through the American National Red Cross. Before military patients are assigned to establishments maintained by the Red Cross Society these establishments will be placed under the immediate direction of a medical officer of the army.

Administrative Organization in the Theatre of Operations.—The theatre of operations is divided into (*a*) the *combat zone*, including division areas, corps areas and army areas; (*b*) the *communications zone*, including all territory from the rear of the combat zone to and including the base. In a large expeditionary force a chief surgeon coördinates all Medical Department activities of the force, including the combat and communications zones; he organizes his office on the basis described above for the surgeon-general's office.

Communications Zone.—The chief surgeon of this zone, as a member of the staff of the commanding officer thereof, exercises immediate control over the Medical Department units therein, such as station and general hospitals, supply depots, training schools, central laboratories, hospital trains, boats and ships, ambulance parks, etc. The function of the Medical Department in the zone of communication is medical procurement, storage and supply, care of the troops within its area, evacuation of sick and wounded, and definitive hospitalization. The following are the more important units: The *general hospital* (formerly termed base hospital) is for definitive treatment, having a normal capacity of 1,000 beds but capable of crisis expansion by tentage to 2,000. These institutions provide every facility for the care of the sick and wounded; certain ones specialize on particular classes of injuries or diseases. The authorized personnel consists of 40 officers, 120 nurses and 312 enlisted men of the Medical Department. The *station hospital* (formerly styled camp hospital) has a standard capacity of 300 beds and serves the immediate local needs of troops belonging to the communications zone. The personnel consists of 13 officers, 35 nurses and 100 enlisted men of the Medical Department. A *hospital train* consists of 16 cars accommodating 360 patients, with a Medical Department personnel of four officers, 40 enlisted men, and female nurses as required.

Combat Zone.—The area covered by this zone includes the troops which are organized into divisions, corps and armies. The Medical Department personnel pertaining to an army, to a corps or to a division is administered by an army, corps or division surgeon respectively, under supervision of the surgeon of the next higher unit. The functions of the surgeon are coördination, supervision and control of the medical service at all times and during combat particularly the relief or reënforcement of the actively engaged Medical Department units by means of army, corps or divisional troops. The work concerns itself only with sanitation, care of troops, collection of casualties and *temporary* hospitalization.

Army and Corps Medical Department Troops.—To an army, in addition to its administrative medical personnel, there are attached four medical regiments, 15 evacuation hospitals, 12 surgical hospitals, one convalescent hospital, one army laboratory, three army supply depots, three army veterinary evacuation hospitals, and one veterinary convalescent hospital; collectively these form part of the army troops. The 15 evacuation and 12 surgical hospitals are for the temporary care of non-evacuable cases and the convalescent hospital is for those practically well and needing little attention, but not yet ready to return to duty. A corps has an administrative medical organization similar to that of an army but smaller; it has one medical regiment as part of its corps troops. The *evacuation hospital* has the primary function of taking over patients from divisional (field) hospitals, established by the hospital companies of a medical regiment, so that these mobile units may move with their divisions; provision is made for very complete surgical treatment if necessary. The capacity is 750 beds and the personnel 38 officers, 50 female nurses and 281 enlisted men. The *surgical hospital* supplements the evacuation hospital for the purpose of handling near the front those cases requiring immediate operation. The bed capacity is 250 and the personnel consists of 19 officers, 20 female nurses and 90 enlisted men. The *convalescent hospital* has a bed capacity of 5,000 and a personnel of 21 officers and 153 enlisted men.

Medical Department Troops Attached to a Division.—The infantry division, which is a basic tactical unit, has a Medical Department personnel of 148 officers and 1,375 enlisted men. Part of these are directly attached to combatant units; the remainder belong to the medical regiment. The *regimental medical personnel* cares for the sick and injured in camp and on the march; supervises local sanitation; goes into action with the troops; and establishes battalion or regimental aid stations where wounded are collected and given temporary care. The *medical regiment*, replacing the sanitary train of the pre-war period, consists of a sanitary battalion, an ambulance battalion with 40 motor and 20 animal-drawn ambulances, and a hospital battalion of three hospital companies, each operating a tent (field) hospital of 250 beds capacity. Its personnel consists of 68 officers (medical, dental and veterinary) and 860 enlisted men. The medical regiment of a division provides personnel for the division surgeon's office and for sanitation of the division area, collects wounded men by litter squads from battalion or regimental aid stations and transports them to the ambulances, maintains wheeled transportation service for movement of casualties, supplies temporary hospitalization, procures and issues medical supplies for the command, renders laboratory service and collects, treats and temporarily hospitalizes sick animals.

The Department's Work in the World War

Sanitary Achievements.—The value of a medical service in war should be measured, first, by the degree to which it preserves the effective strength of the army by sanitary methods, and, second, by its success in evacuating and caring for the sick and wounded. In both respects the Medical Department of the American army attained notable results. The success in preventing infectious diseases and losses from them, as compared with the Civil and Spanish-American Wars, is shown by the fact that only 6,445 fatalities occurred as a result of typhoid fever, malaria, dysentery, smallpox, scarlet fever, diphtheria and other miscellaneous communicable diseases (excluding tuberculosis and pneumonia), whereas if the Spanish War rates had prevailed there would have been 101,439 deaths, and if the Civil War rate had prevailed there would have been 170,997 deaths from these causes.

Care of Sick and Wounded.—In the succour of the sick and wounded great advances were made both in the theatre of operations and in the service of the interior. Personnel directly attached to combatant organizations was greatly increased. Mobile surgical hospitals were organized and operated close to the front; X-ray examinations were everywhere available; splints for use in transporting fracture cases were enormously improved. Motorization of ambulance service was carried to an extent hitherto undreamed of. Base hospitals were enlarged to accommodate 1,000 patients or more, and were frequently grouped in centres, sometimes aggregating 20,000 beds, including the crisis expansion under canvas. In such centres the individual hospitals specialized, one treating gassed cases, another head cases and others chest wounds, fractures, abdominal injuries and medical patients respectively. Laboratory service both at the front and on the lines of communication was expanded beyond all precedent. Professional services were more carefully coordinated and supervised than ever before; the most expert personnel was divided into groups, such as operating teams, gas teams, shock teams, etc., for quick transport by automobile or train to points where need was greatest. Veterinary units were augmented in size and number, caring promptly for sick and wounded animals. In the zone of the interior hospital service was brought to the highest standard, the best professional talent of the country was mobilized, and notable progress was made in the treatment of the sick and injured, particularly in the direction of physical reconstruction of the wounded, with a view to returning the individual to the community as a self-sustaining citizen.

Physical Examinations.—Nearly 4,000,000 officers and men were given a careful physical examination by the Medical Department before admission to the military service and approximately the same number were again examined before demobilization; careful records thereof protect the interests of both the individual and the Government. Valuable data as to the physical status of the nation were obtained from an analysis of these examinations.

Personnel.—On April 6 1917, the Medical Department personnel was not even sufficient for the peace-time needs of the small regular army. The increase is shown in the following table:—

April 6 1917		November 30 1918 (Approximate)	
Medical Corps	491		
Medical Reserve Corps, on active duty	342	Medical Corps	30,500
Dental Corps	86	Dental Corps	4,600
Veterinary Corps	62	Veterinary Corps	2,000
Contract Surgeons	181	Contract Surgeons	940
Civilian employees	450	Civilian employees	10,700
		Sanitary Corps	2,900
		U.S.A. Amb. Service	206
Nurse Corps	233		
Reserve Nurse Corps on active duty	170	Nurse Corps	21,480
Enlisted Personnel	6,900	Enlisted Personnel	264,000

Hospitals.—When war was declared the army possessed four general and 113 small station hospitals with a total capacity of 6,665 beds. At the height of military activities there were in the United States 47 general hospitals, about 40 large base hospitals (ranging in size from 800 to 3,000 beds each) and a great number of smaller hospitals; the total capacity was over 130,000 patients. In the A.E.F. at the time of the Armistice, Nov. 11 1918, there were in operation 153 base, 66 camp and 12 convalescent hospitals with a bed capacity of 283,553. By Dec. 5 this capacity had increased to 296,865 and with buildings already leased, under construction or authorized, would in due course have reached 423,722, with crisis expansion to 541,000. (W. P. C.)

ARRIAGA BRUN DA SILVEIRA E PEYRELONGUE, MANOEL JOSÉ D' (1830–1917), Portuguese politician, was born at Horta, in the Azores, in 1830. He was educated at the university of Coimbra, where he took his degree in law in 1866. He became known as a strong Republican, and in 1882 was elected deputy for Funchal, in 1890 becoming deputy for Lisbon. His Republican principles caused him to be a figure of much importance at the time of the revolution of 1910, and on Aug. 24 1911 he was elected first president of the Portuguese Republic (*see* PORTUGAL). He resigned office in 1915, and died March 5 1917.

ARROL, SIR WILLIAM (1839–1913), British engineer, was born at Houston, Renfrewshire, Feb. 13 1839. In his boyhood he was apprenticed to a smith at Paisley, and worked through several engineering shops until, in 1868, he was able to set up as a boiler-maker. In 1872 he took up construction in steel and started the Dalmarnock ironworks, becoming an expert in bridge-building. The Caledonian Railway bridge at Glasgow, the reconstructed Tay bridge (1882–7), Forth bridge (1882–9), the Tower bridge, London, and the Nile bridge at Cairo were amongst his principal achievements. He was knighted in 1890. He sat in the House of Commons for Ayrshire (S.) as a Unionist member from 1895–1906. He died at Ayr Feb. 20 1913.

See Sir Robert Purvis, *Sir William Arrol* (1913).

ARTILLERY (*see* 2.685).—Before the World War, the general military ideas of artillery procedure and purposes were somewhat the same in all countries.

It is proposed here to consider the lessons of the World War in the order in which they were learnt. As the war progressed, fresh problems presented themselves, fresh necessities arose, and artillery methods, equipment, and organization had to be modified to meet them.

The war on the western European front may be divided into four phases: a dash by the invader into the enemy's country; a long period of immobile warfare, both sides entrenched; and the breaking of the line, followed either by retreat and reconstruction or else by the full exploitation of victory.

The first, or mobile, phase of a modern war is of the greatest importance; it decides whether the campaign is to be fought in the defender's country or in the invader's. When one country attacks another, it is the object both of her statesman and her soldiers to make the initial dash as rapid and effective as possible, so as to finish the campaign in the first stage, and to avoid the long war of attrition which results when two nearly equal armies are entrenched. Similarly, the defender endeavours to crush the invading force at the outset, or to drive it back into its own territory. Therefore, in pre-war preparation, the requirements of trench warfare must be subordinated to those of mobile warfare.

In the World War, at least four-fifths of the main Western campaign was fought in the trenches; and the only seriously contested campaign in which the first phase was carried through to a finish was the invasion of Rumania by the Germans. Even in Allenby's brilliant Palestine campaign there was a long pause after the taking of Jerusalem. It seems highly probable that the longest, though not the most important, period of a future war will consist of trench warfare. Speculation as to the effect of new weapons, such as tanks, aircraft, and gas, in changing the nature of war, may be as misleading as regards the future as it has been in the past, and, at the least, it is necessary, at the present time, to provide for trench warfare as well as for mobile warfare in the training and equipment of an army.

I. Mobile Warfare

Mobility.—The initial phase of a war requires a high degree of mobility. Once the invader has left his own railways behind, he must, at first, depend almost entirely on roads. He desires to advance at the rate of 50 miles a day, which is a very different matter from covering 10 m. an hour over short distances. The defender requires an equal degree of mobility to counter the attack. Motor transport for guns and infantry is the only means of attaining this marching pace. As regards the artillery, with which we are here concerned, the gradual disappearance of the civilian "van horse" will, in course of time, make it difficult to keep up horsed guns in peace time, and impossible in war. There is therefore a general agreement that the artillery must become motor artillery. It is obviously impossible to make such a change all at once; the question is, which natures and formations should be converted first. Before dealing with this point we may consider the types of artillery motor required.

The weight of artillery opinion is against the automobile gun-carriage, which is too large to dig in or conceal, and too vulnerable; moreover, the motor is useless when the gun is in action, and might better be employed elsewhere. Pulling a gun behind a tractor has many advantages, and is economical of transport, since the tractor carries the men and first supply of ammunition. The difficulty is that an ordinary Q.F. gun-carriage breaks up when drawn by a tractor at any pace faster than a walk. In March 1918, at the time of the German attack, the French brought up a large number of field guns drawn by lorries. These guns had to be fitted with rubber-tired wheels for the purpose. Again, in the autumn of 1918, the French (who were by then very short of horses) used field guns carried on lorries, with the gun-teams carried in motor-omnibuses converted into horse-floats. Only sufficient horses to bring the guns into action were transported in this way. By the end of the war the French had 266 tractor-drawn batteries of divisional artillery, and 306 batteries on lorries.

The French sometimes adopted a still bolder solution of the problem, namely, carrying the 7-ton caterpillar tractor on a special road lorry. Some authorities are disposed to think that this heroic method offers a better prospect of success than trying to produce a tractor that shall be able to cross country and also to travel fast on the road without damage to the surface. For a light caterpillar tractor, capable of pulling a field gun across country, may be made to weigh 50 cwt. or less, so that a large 4-ton lorry can carry both the tractor and a 30-cwt. field gun as far as the point where the gun has to leave the road. However, the method of carrying one motor on another seems so wasteful that it is regarded as a last resource.

The Italians have tried carrying the guns on lorries, with ramps to run them on and off, but find the system wasteful of transport; the gun takes up so much space on the lorry that there is no room to load it to its full capacity with men and ammunition. In 1921 they were experimenting with low-travelling platforms, of which one or possibly two are to be drawn by elastic couplings behind a fast road tractor; the platform, which carries a wheeled field gun, is on rubber-tired wheels and is supported on road springs so as to run smoothly at 12 m. an hour. These are for reserve "army" field artillery, and the guns are to be drawn into position by the horses, or cross-country tractors, of the divisional artillery which they reënforce.

There is one set of conditions under which the carrier has the advantage of the tractor, and that is in getting guns forward over the "crater-field" when this is very boggy. In the zone of contact of two hostile forces, when these are entrenched, the ground is pock-marked with shell craters, and in wet weather it may become a swamp into which any wheeled vehicle sinks, even if it is attempted to drag it behind a caterpillar. There are certain conditions of ground over which a caterpillar can carry a gun, though it cannot drag it. These must, however, be considered exceptional, and too rare to justify the adoption of carriers in place of tractors. Moreover, the sinking of the gun may be obviated to a great extent by using "girdles," which are linked plates surrounding the wheels. Girdles are also used on wheeled tractors for crossing soft ground.

A very important factor in the question of the motor transport of artillery is the necessity of using the agricultural motors of the country in time of war. The French are now endeavouring to produce an agricultural tractor, mobile on and off the road, which shall fulfil military requirements and shall also be used in very large numbers for agriculture. The introduction of a proportion of automobile gun-carriages, though spoken of by the French press, is a question which is still unsettled. The French guns up to the 6 in., and howitzers up to the 9·45 in. inclusive will be road-mobile, being divided into tractor loads, where possible not exceeding 5 tons net. All heavier natures will be on railway mountings.

In Italy, the intention is to have all the divisional artillery (which is to consist of field guns and field howitzers only) drawn by small agricultural tractors, road speed 5 m. an hour. These are not to be caterpillars but four-wheel-drive motors, and it is considered that the pattern adopted (Pavesi of Milan) will be sufficiently mobile across country. Girdles are carried for use on soft ground. The army field artillery will be drawn by fast road tractors as mentioned above. The corps artillery, consisting of 4-in. guns and 6-in. howitzers, will be drawn by wheeled road tractors of 50 and 55 H.P. These are also used for the component parts of heavy artillery loads up to the 12-in. howitzer inclusive. These also carry girdles for soft ground.

The question of artillery transport is more urgent in Italy than elsewhere, since the country produces no artillery draught-horses. Italy is the only country which has actually begun the conversion of horsed to motor artillery; the United States and France, though they used motor artillery during the war, are still only preparing to introduce it as part of their permanent organization. The Italian "*auto-portata*" army regiment of 48 field guns referred to above is the only such unit in existence. The reason why wheeled tractors, not caterpillars, have been preferred is that owing to the nature of the cultivation there is no prospect of cross-country agricultural tractors of the caterpillar type being used on any large scale.

The United States are trying both tractors and automobile gun-carriages; apparently they do not favour platform carriers.

The order of conversion of the different horsed artillery formations to motor transport will probably, in all countries, be on the following lines: (1) All transport which keeps to the road, including ammunition columns; (2) all guns and howitzers heavier than the divisional artillery; (3) army field artillery; (4) all first-line ammunition wagons; (5) guns and fighting battery wagons of the divisional artillery. It is, however, an open question whether army field artillery should not be converted to motor transport first of all, on account of the high importance of having a reserve of field artillery, able to travel long distances at a fast pace, available on the outbreak of war.

It need hardly be said that in future the artillery motors of the fighting formations will belong to the artillery and be driven by artillery drivers, not by men borrowed from the general transport corps of the army.

Road-Mobile Super-Heavy Artillery.—One of the first surprises of the war was the reduction of the strong fortresses in Belgium and northern France by the German super-heavy artillery. These fortresses were designed to resist 6-in. guns and 8-in. howitzers, and the Germans brought up 12-in. and even 16·5-in. (42 cm.) howitzers by road to attack them. The limitations of the transport of heavy loads by road vary in different countries. The British used 22-ton traction engines in the S. African War of 1899–1902, at the end of which they were sold out of the service as too heavy for English bridges. The bridges on the continental "national" roads are stronger than most English bridges, and, on some routes, are capable of taking a gross load of 30 tons on four wheels. The 42-cm. howitzer was divided into loads, the heaviest of which was about 29 tons gross. It was no doubt built with regard to the roads by which it would have to travel. A short (25-calibre) 9·2-in. gun or long 8-in. gun would make loads of the same weight. However, in France it has been decided, as mentioned above, not to transport super-heavy ordnance by road. These pieces are all to be on railway mountings. The reason for this is the greatly increased range which was demanded of howitzers during the war; thus the British 6 in. howitzer in use in 1914, which ranged 6,000 yd., was replaced by a howitzer of the same calibre ranging 11,600 yd., and a similar increase of range was required of all pieces which, before the war, were classed as siege artillery. It is therefore considered that it will always be possible to find or to build a position for heavy guns and howitzers on railway mountings within range of a fort or of any target which they may have to engage.

Liaison.—An early experience of the war was the breakdown of the method of coöperation of infantry and artillery which had been taught in peace time. The French were the great exponents of this method. It consisted of *liaison par le haut*, which means, for instance, that the divisional commander details a *groupe* of three batteries to support the attack of a brigade of infantry; and *liaison par le bas*, which means that the infantry brigade and artillery group commanders, and even their subordinates, the battalion and the battery commanders, keep up constant communication during the fight. Under battle conditions, *liaison par le bas* broke down at once. The British did rather better than the French, because they had five officers per battery as against three, and because they were trained in the use of the concealed artillery position, which necessitates distant communications. During sedentary warfare communication was perfect; every company in the front-line trench had a battery to support it, and the battery prided itself on putting over a storm of shrapnel within 10 seconds of receiving the call for assistance. But as soon as the troops left their trenches, in advance or retreat, direct communication between infantry and artillery units ceased altogether. Telephone lines were cut by the enemy's fire; visual signallers were shot down, or, even if they succeeded in finding cover, the smoke and dust soon interrupted their view. Orderlies rarely succeeded in getting through, and the few that escaped being killed or wounded arrived too late for their messages to be of any use. Many devices were tried by the armies engaged; the German system of light signals was the least unsatisfactory. But the direct and intimate coöperation of infantry and artillery units was never realized.

The Barrage.—This breakdown of communications obliged the contending armies to adopt a simpler means of coöperation, and led to the general introduction of the "creeping barrage" (French *barrage roulant*, German *Feuerwalze*). Briefly, it is a screen of shells bursting on and close to the ground, which is moved forward across the country by short leaps according to a pre-determined time-table. It is "halted" on each successive objective for some 10 minutes before the infantry assaults it, in order to intensify the effect. It is then moved forward again to screen their further progress, and, when the last objective has been reached, it becomes a "standing" barrage to screen and protect the troops while they "consolidate" the ground which has been gained.

The infantry follow behind the barrage, keeping just clear of the zone of bursting shell. They are screened from aimed fire by the smoke and the dust thrown up, and the barrage is intended to destroy any opposition as it passes on. If it succeeds in doing this, communication between infantry units and the supporting artillery becomes superfluous. It has proved practically impossible to control or check the pace of the barrage when it has once started, although the Germans attempted to do so by light signals. This is on account of the difficulty of passing the information from the particular infantry unit which wants a modification of programme to the particular battery or batteries concerned with that part of the barrage, through a "chain of command." For at least one gun per 20 yd. of barrage front is used, and the batteries whose concentrated fire forms the barrage may themselves be widely dispersed.

Similar creeping barrages are used to screen retreating troops, though the problem is then more difficult, since the enemy dictates the pace of retirement. Such barrages are therefore made as simple as possible in plan and in execution. Other forms of barrage are used. "Flank" barrages are used to screen the flanks of troops, either halted or in motion. "Standing," as opposed to "creeping," barrages are used for many purposes, such as to prevent the enemy from rëinforcing a portion of his line which is being attacked. A form of standing barrage often used for this purpose is the "box" barrage, consisting of one barrage parallel to the front attacked and two at right angles to it, forming three sides of a rectangle. A "preventive" barrage is put down over the enemy's lines when he is supposed to be about to attack. A "counter barrage" is one put down when the enemy is actually attacking, so managed as to take effect on his troops as they follow up their own barrage. In some instances a sham barrage, with no troops behind it, was used to divert attention from the real attack.

Important as the barrage is, it cannot be considered a satisfactory substitute for aimed fire; it is an expedient which has to be resorted to when fire of precision cannot be carried out. Marshal Foch had occasion to warn the French artillery against trusting too much to it. In a circular issued in the summer of 1918, he writes:—

"The rolling barrage adopted by the Germans no longer meets the conception of the present war. The artillery cannot pretend to overwhelm the entire terrain of the attack with a rolling barrage, even if redoubled. Its object is not gained by unloosing a brutal fire over a given zone and searching progressively at random with a fire directed straight to its front, without regard as to whether it is followed by the infantry. It is better to attack definite points and intensify the interdiction, the counter-battery, or the crushing fire on certain points, reserving a part of the field batteries for accompanying the infantry in intimate cooperation with it."

In other words, it is unsound to abandon at the outset all fire of precision on important targets, and every endeavour to work in coöperation with the infantry, and, instead, to attempt to mow down all opposition with a machine.

The Barrage in Mobile Warfare.—Although the creeping barrage is primarily used in the deliberate attack on an entrenched position, even in mobile warfare troops are frequently checked by an enemy holding an improvised position, and it may then be necessary to bring up all available artillery at once, and to form a creeping barrage to cover the attack. When an attack is led by tanks, it is necessary to have a barrage to conceal them, otherwise a great many are hit.

Wireless telegraphy may possibly be so developed as to become both directive and selective, so that a hundred stations may talk at once without mutual interference, or risk of being "jammed" by the enemy. Some progress in this direction has already been made. If this or other reliable means of sending and receiving messages becomes a practical fact, it will solve the problem of communication between infantry and artillery, and the crude method of barrage will fall into disuse.

Guns of Accompaniment.—As the creeping barrage advances it is intended to destroy all opposition. But it was found in practice that enemy detachments provided with good cover, such as machine-gun sections with overhead protection, got underground while the barrage was passing over them, and then reappeared, causing very heavy losses to the attacking troops. The French ascribe the majority of their losses in the last phase of the war to this cause. Now it would be extremely dangerous, even if it were possible, to bring the barrage back to "pound" such a danger spot. By the time this had been done, the advancing troops might very possibly have disposed of the machine-guns by bombing, and have resumed their advance, in which case they would come under their own barrage fire. It is manifestly impossible to get the fire of distant guns on to a machine-gun nest in time, though something might be done by an aeroplane dropping a light-ball on it to attract the attention of the guns. The result of the failure of artillery support in this matter has been a general outcry for guns of accompaniment; that is to say light guns, either pack, motor, or hand-drawn, capable of advancing with the infantry, and of dealing with machine-gun nests and strong points that have survived the barrage, and with tanks.

The matured German opinion is expressed in the following quotation from a document issued scarcely 10 weeks before the Armistice:—

"The guns of accompaniment must engage at short range the enemy with whom the infantry is fighting at close quarters. By reason of their proximity to the infantry they can be fired at the right moment, and on the right target, more easily than the artillery in rear. Also, being at close range, they can fire on objectives which cannot be observed from the rear."

A light 9-pounder, firing H.E. shell only, to an effective range of about 2,000 yd., is the type of weapon required. The British used their 3·7-in. mountain howitzer, firing a 20-lb. shell, when available; but the ammunition was considered too heavy, and troops who possessed captured German light trench mortars, firing a 14-lb. shell, found this a better weapon for the purpose. The latest type of gun is the U.S. "infantry howitzer," which is carried so far forward as possible by a small cross-country motor vehicle, and thence wheeled or carried by hand. It fires a 6-lb. shell for direct fire, and a 9-lb. shell for high-angle fire.

These guns are required at the rate of about one per 100 yd. of the front of the advance, or from 12 to 16 per division. The French have decided that a gun of accompaniment is to be introduced, and it is understood that it will be motor-drawn or motor-carried, but no further details are available. The Germans, in 1917 and 1918, used a variety of light guns styled "infantry guns" in addition to their infantry trench mortars, which were fitted for direct as well as for high-angle fire. But in the great 1918 battles their invariable practice was to detail one, two or more batteries of the divisional field artillery, fully horsed, and with their own ammunition carriages, to support the divisional infantry attack by direct accompaniment (sometimes reënforced). After trying other methods, they finally adopted the practice of allotting sections, or even single guns, to the battalions engaged. These single guns or sections followed up the leading lines of infantry, running up by hand when the horses could not get forward.[1]

[1] The relation of the artillery commander to the infantry commander, both being on the spot, was a difficult question which was never definitely solved. In practice, indication of task was as a rule the duty of the infantry commander, and choice of position and method that of the gunner. But the latter remained free to engage any favourable target without waiting for orders. (C. F. A.)

Gun-Carrying Tanks are here considered as gun-carriers. A war-time tank normally carried two short 6-pounder guns, one on each side, and 200 rounds of ammunition; it could carry another 100 rounds if required. If the tank were made larger, it could carry a 12-pounder or 18-pounder gun inside. When the gun is put outside, on the top, the machine ceases to be a tank and becomes an automobile gun-carriage or a caterpillar carrier; these have been discussed on pp. 248-49.

The volume of fire from a tank is not sufficient to constitute a decisive factor in the combat. Fire with shrapnel and time fuze from a moving tank would be a waste of ammunition, and the tank would not last long if it stood still. The small H.E. shell is nearly useless against men in the open, and the case-shot which the tank carries is effective only at very short range. The guns of a tank cannot be expected to engage infantry manning a trench parapet, and keep down their fire, except when the tank succeeds in getting astride of the trench and firing down it to right and left. Even then the effect is rather moral than material, since the infantry are protected by the traverses and indentations of the trench, which are specially designed to prevent enfilade. Practically, there are only two things that the guns of a tank can do, but these are both important. They can destroy an enemy tank, and they can put a H.E. shell into a machine-gun emplacement at short range, long before a message could be got through to a field gun a mile behind. For both these purposes the 6-pounder gun is sufficiently powerful, though it is possible that thickly armoured tanks may be introduced which will require a heavier weapon to pierce them. Quite apart from its gun-power, the tank supplements and sometimes replaces artillery fire by its power of crushing obstacles, notably barbed wire and iron palisades.

It remains to be considered whether the tank is a satisfactory substitute for the infantry gun of accompaniment. The advocates of tanks anticipate that in future an infantry attack will be carried out on the following lines:—In front of all is the creeping barrage, closely followed by the infantry and the light tanks ("cruisers") armed with machine-guns and possibly 6-pounders; behind these come 18-pounders or heavier pieces on armoured automobile carriages ("battleships"), and small fast caterpillars ("destroyers") carrying tank-stopping machine-guns. Just before the assault the "cruisers" dash forward in advance of the infantry, supported by the fire of the "battleships" and escorted by the "destroyers." The "battleships" also deal with machine-gun nests and strong points that have escaped the barrage. As the infantry continue their advance, the motor-drawn guns behind, which have been forming the barrage, advance by echelons to fresh positions behind the infantry, and carry the barrage forward.

Supposing an attack on these lines to be carried straight through, no infantry guns, capable of fighting on their own wheels, would be required. But it is objected that if the infantry attack were checked, as is inevitable at times, their only guns of accompaniment would be the large and conspicuous "battleships," which are very vulnerable when standing still. The same objection would apply in a retreat, which is a series of halts to check the enemy. It would appear, therefore, that the infantry gun must be separable from its motor, so that it can fight, and conceal itself, on its own wheels. Neither the "cruiser" nor the "battleship" tank satisfies this condition, but it may possibly be desirable to introduce a tank which shall carry a light gun to the fighting front, dismount it, hand it over to the infantry, and then advance on its own account, with its machine-guns, as a fighting tank. No tank of this kind has yet been tried, and moreover there is no present prospect of the large and expensive armoured "battleships" being provided in any army. Manufacture on the large scale would probably not begin till the outbreak of war. In the meantime, the infantry gun of accompaniment will have to be developed as an infantry weapon, independently of the "land fleet." Whether it should be motor-drawn, motor-carried, mule-carried or man-handled is still an open question. Many officers are in favour of a gun drawn by a small tractor, to take it as far forward as possible; the gun to be light enough to be man-handled when the tractor fails. The American infantry howitzer referred to above realizes this idea, except that it is carried instead of being drawn.

Artillery Fire at Tanks.—The best means of stopping tanks is still an open question. It would at first seem a simple matter to make direct hits on them, but in practice the enemy's barrage and bombardment interpose a screen of bursting shells behind which the tanks can approach unseen. Moreover, it is not easy to find a position affording a good view, from which the gunners can lay over the open sights, within 2,000 yd. of the front line. Indirect laying is too slow for moving objects. When preparing to meet the German advance of March 1918, the British plan was to hide a number of field guns in or close to the front line, which were to keep silent till tanks appeared, and then fire on them. These guns were never heard of again; they were all destroyed by the intensive bombardment which preceded the attack. In some cases, land mines were buried under the barbed wire entanglements to prevent the tanks from "rolling them out," but these mines rarely survived the bombardment. They might be useful, however, if the enemy attempted a surprise attack with tanks without a preliminary bombardment. The best means of resisting a tank attack on an entrenched position would appear to be the provision of numerous small anti-tank guns in the trench area, as described below.

In mobile warfare the conditions are somewhat different; in the autumn of 1918, when the British alone used 2,000 tanks, many of these were destroyed by the German rear-guard batteries, and by concealed guns left behind for the purpose. The Germans used heavy single-loading "anti-tank rifles," pending the introduction of large calibre "anti-tank machine-guns," and it is stated that a tank-stopping rifle grenade, fired from the muzzle of an infantry rifle, has lately been produced. It would seem, however, that in open warfare the most formidable opponent of the tank is the enemy tank, and it is probable that a special type of light fast tank—a "tank destroyer"—armed with one gun amidships, or even with a heavy machine-gun only, will be introduced.

II. Trench Warfare

The lessons of the first phase of the war had been the necessity for a high degree of mobility, the breakdown of direct *liaison* between infantry and artillery, and the weakness of permanent fortifications of old-fashioned type when attacked by modern guns. When the armies settled down to "sedentary" trench warfare, a fresh set of problems presented themselves.

At first, the trench system, however multiplied in detail, was simple and continuous in the ensemble; in 1915 a system often consisted of three lines or skeins of trenches half a mile apart and connected by communication trenches. But, in the latter part of the war, different principles were followed, and a modern trench system is not a single strongly garrisoned line, in which the troops would offer an easy target to artillery, but a fortified zone two to three miles in depth. The front nearest to the enemy is not a continuous parapet; it is dotted with inter-supporting points of resistance, varying from a shell-crater holding three men to an armoured "pill-box" or a fortified "strong point" held by a platoon with machine-guns. The actual front trench may be a mile behind the front of the system, and in any case is not visible to the enemy. It is dug on a reverse slope when possible, as a field of fire of 100 yd. is quite enough for modern rapid-firing rifles and machine-guns. Even the front trench is often not continuous, but consists of short lengths arranged so that each can be enfiladed by guns, or more usually machine-guns, in rear. It is a chain of defences, rather than a continuous barrier. Behind the front trench is a network of fire trenches, strong points, and communication trenches from one to two miles in depth; this is a styled the "battle zone." Behind this is the second-line trench, which forms the front of the "reserve zone." Still further to the rear there may be second and third trench systems and reserve lines. The ground in front of the battle zone is the outpost zone, and is not intended to offer serious resistance. Its function is to screen the

battle zone, and to delay an attack long enough to allow the battle zone to be manned.

The field artillery have three sets of positions, known as forward, main, and reserve. The forward positions are in the battle zone, and the guns posted there are intended to protect the outpost zone, and to support minor attacks made from this zone (*see* p. 253, *Warfare between Front Trenches*). The main positions are 3,000 to 4,000 yd. behind the front trench, that is, in the reserve zone, some 1,000 yd. behind the second-line trench; the guns posted in the main positions barrage the front trench and support the infantry in the battle zone. The reserve positions are 3,000 to 4,000 yd. behind the second-line trench, and the guns, when they occupy them, barrage the second-line trench and support the infantry in the reserve zone.

Normally about one-third of the divisional field artillery are in the forward positions and two-thirds in the main positions. The reserve positions are ready for occupation and supplied with ammunition.[1]

The medium and heavy artillery are behind the field artillery, and the wagon lines are out of field-gun range, that is, at least 5 m. from the enemy's field artillery positions. Additional artillery positions are prepared, so far as the supply of labour permits, for reënforcing units, which are put in when it is intended to attack, or when an enemy attack is threatened. All guns normally belonging to the front are in emplacements provided with overhead cover, and carefully camouflaged against the camera. All fire trenches and entrenched posts (called "strong points") are protected by entanglements of barbed wire. Artillery observing posts ("O.P.'s") from which the fire of the batteries is directed, are disposed wherever they can be concealed, and the whole system is connected up by an elaborate network of telephone wires, the main lines being (in British practice) deeply buried.

The arc of fire required of each battery has to be considered when siting and entrenching it. The following is a typical arrangement, subject to considerable local variation. It applies to a division of three infantry brigades of four battalions, three field-gun brigades of four batteries, and one field-howitzer brigade of four batteries. Each infantry brigade holds one unit of front, about 1,000 yd., and is supported by one field-gun brigade. Of the four batteries of this brigade, three cover their own unit of front and can cover one more unit on each side, making 3,000 yd. of front; the fourth battery is a "swinger," and covers two units on each side of its own unit, making 5,000 yd. of front. All the field-howitzer batteries are swingers. This arrangement enables the division to turn 13 field batteries on to any point on its own front, and to turn 6 field batteries on to the front of either of the neighbouring divisions when called upon. The medium, heavy, and super-heavy guns and howitzers are all sited, when possible, so as to engage any target within their range.

Under these conditions, as soon as trench warfare began, artillery fire became a matter of very careful preparation and rapid execution. A battery was liable to be called on suddenly to fire on any one of a hundred different targets, visible from an O.P. or not. The first essential was to get every gun to shoot to map range. In open warfare, artillery firing at visible targets neglect the "error of the day" due to variations of temperature, barometric pressure, and wind, since this is corrected by direct observation of fire. In the trenches this error became of great importance; it might, and did, make the difference between hitting the enemy or our own infantry. The daily "Meteor" telegram from the meteorological section of the army corps was supplemented by reference to the thermometer and wind-gauge whenever a battery opened fire. Worn guns were carefully "calibrated" so that their error could be allowed for; this was done at special ranges behind the front, or, when this could not be done, by firing at known points in the enemy's lines. The next matter was to obtain an accurate map, with the positions of the batteries and their targets marked on it, so as to enable the exact map range to be measured.[2] The result of this work was a great improvement in shooting, and consequent economy of ammunition. Unfortunately the varieties of powder supplied caused a further complication. It proved impossible to distribute the ammunition so that each brigade had always one particular nature or brand of powder, except on special occasions, when preparations were made for a great attack. It was therefore customary, in trench warfare, to "register" all prospective targets, or at least points near them.[3]

Howitzers.—The necessity for searching deep trenches and penetrating overhead cover gave rise to a demand for more howitzers. The field gun, firing shrapnel, was invaluable when the enemy moved about their trenches, or showed themselves over their parapets; at other times shrapnel was of little use, except for barrage. The field gun H.E. shell was too small to penetrate parapets, and the field-howitzer shell did not penetrate well-built dugouts. All the belligerents found that the most useful weapon for bombardment was the 6-in. (15 or 15·5 cm.) howitzer, throwing a shell of 100 pounds. The Germans in particular regarded this as their most important weapon for trench warfare. In 1914 the British army had only a few old-pattern 6-in. siege howitzers, but from 1915 they had a 6-in. Q.F. howitzer ranging 10,000 yd., which range was afterwards increased to 11,600 yd. by the issue of stream-line shell. By the end of the war the British had 6,437 howitzers in France alone; 3,633 6-in. howitzers had been issued, and 1,458 were in the line on Armistice day, which shows the rate at which they were worn out. They fired over 22,000,000 rounds.

Similarly in 1914 the French had only 300 howitzers of 155 mm., of which 104 were mobile. In 1918 they had 6,000 of this and larger calibres.

The heavy and super-heavy howitzers, 8-in. (21 cm.), 9·2 or 9·4-in. (24 cm.) and higher calibres were used for work too heavy for the 6-in.

For all calibres over 6-in., howitzers soon began to supersede guns, though a few flat-trajectory heavy guns were used. The reason for this was a question of supply. A howitzer firing at 45° gets its shell to the target with a much smaller powder charge than a high-velocity gun, and consequently lasts perhaps 10 times as long before it has to be retubed.

Increased Range.—The precision with which "map fire" could be carried out by the methods described above led to headquarters, wagon lines, ammunition "dumps," and installations behind the lines being shifted to greater distances from the front. This created a demand for increased range. When the Germans initiated the system of covering the front with a zone of "pill-boxes" and small posts, and withdrawing the front trench (or its equivalent chain of short trenches) a mile behind the front of the defended zone, the ranges were still further increased. Even before this, the Germans had lengthened their field gun and brought out a stream-line shell which increased its range from 6,000 yd. to 11,700 yd.; their old field howitzer ranged 7,600 yd., their 1916 pattern 10,500 yd., and similarly with the 6-in. howitzer and larger calibres. Other nations did the same; the French altered the trail of their 75-mm. field gun so as to get more elevation and increase the range to 11,000 yd. with stream-line shell, and introduced their short 19-cm. gun, converted

[1] The British, who used 6-gun batteries, used to keep two guns of a battery forward and four in the main position; with 4-gun batteries it is not usually advisable to split them up. The Germans used to keep the whole of their field guns in the main and reserve positions, and these were further back than those described above; guns were sent up to the advanced positions for special tasks only, and were withdrawn as soon as these had been completed.

[2] This resurvey often showed local landmarks to be 100 or 200 yd. from their positions as marked on the original maps.

[3] Registration consisted of firing a series and noting the result, corrected to standard "Meteor" conditions. These series were observed from O.P.'s when possible, otherwise by aeroplanes or sound-ranging. Thus when an enemy working party was reported by an aeroplane in Trench 56, a battery commander got the order "Target 56 stop 25 shrapnel 25 HE Fire." He looked up 50 in his registration book, corrected the recorded elevation, direction, and fuze for "Meteor" and powder in use, gave his orders, and his guns fired the 50 rounds in half a minute. The aeroplane observed the result, which was entered in the registration book for future reference.

to an 8-in. howitzer. In guns designed since the war the increase of range is very marked; thus the United States require 15,000 yd. of range for their new field gun; the latest pattern of British 18-pounder issued during the war ranged 10,800 yd., and the forthcoming pattern will probably range as far as the U.S. gun.

Hundred-Mile Guns.—This general increase of range culminated in the German gun or rather guns (colloquially called "Big Berthas") which shelled Paris from a distance of 76 miles.[1] As early as 1915 the Germans shelled Dunkirk from a point 25 m. distant with a 14-in. naval gun, and they proposed, if they succeeded in driving the Allies back from Calais, to use 110-mile guns which should command the whole of the British coast from Yarmouth to Southampton, and the whole of the London district. Such guns are not specially difficult to make, and both the British and the French artillery authorities had worked out the design of 100-mile guns some years before the war. In principle they depend on firing a shell upwards so as to clear the dense layer of air lying next to the earth, and to attain a height of some 25 m. where the air is so rarefied as to oppose practically no resistance to the flight of the shell. Seven of these guns were used against Paris in 1918, and at the end of the war the Germans had six more building; the British, French, and Italian Governments had each at least one of these guns building, but it is understood that none of these were completed. Owing to the high powder pressure employed, and consequent high temperature in the bore, the life of the German guns was only about 50 rounds, after which they had to be rebored. For this reason the 100 mile gun marks about the limit of practical possibility with propellants now in use. But, if it were considered advisable, it would be possible to make a special powder giving lower temperatures than the gun-cotton and nitro-glycerine powders now in use, and so increase the life of these guns.

Flashless Powder.—During "sedentary" warfare, any gun which fired at night within direct view of the enemy was liable to be marked down by the "flash-spotting" section opposite to it, who got cross bearings to it, after which it was soon shelled out. It was therefore necessary to introduce flashless powder, or else to add a portion of special chemical composition to the ordinary charge for all guns which could not be hidden behind woods or hills. The United States have specified that it is to be used in their new field gun.

Ranging by Aeroplane.—Apart from the work done by aircraft in locating targets by direct observation or by photography, they were used during trench warfare for ranging on targets which could not be observed from the ground. The aeroplane was from the first fitted with a wireless sending set; but it was only towards the end of the war that practical forms of receiving apparatus were evolved, and, generally speaking, messages to the aeroplane had to be sent by code signals, which were strips of white cloth laid out on the ground near the battery. Only simple signals such as "Ready to Fire" could be used; it was therefore necessary to arrange the details as to the target to be observed beforehand. Ranging was carried out deliberately, the aeroplane sending down the result of each shot. Only one such series could be fired at a time on an army corps front, as, with the instruments then in use, if two aeroplanes had been sending wireless at the same moment they would have interfered with each other. Until the means of wireless communication are improved, aeroplane ranging will remain too slow and elaborate a method for field artillery in mobile warfare, though it may be applied to heavy artillery.

Sound-Ranging.—This is described under RANGEFINDERS AND POSITION FINDERS. It consists in measuring the intervals of time at which the sound of an enemy gun successively reaches three or more stations, and, from the differences, calculating the position of the gun. It also enables the point at which one's own shell bursts to be located. The installation of these stations takes about a day, and in certain conditions the method cannot be depended on or indeed used at all. In mobile warfare, sound-ranging may possibly be used to locate the enemy's heavy guns.

[1] The bombardment of Paris was spread over 140 days; firing took place on 44 days only. 183 8-in. shell fell in Paris, and 120 in the suburbs. The material effect was slight (256 people killed in 4½ months) and the moral effect, after the first day, inconsiderable.

Warfare between Front Trenches.—Simultaneously with the long-distance shooting at targets behind the fronts, constant fighting took place between the front trenches, which, early in the war, were in some places only 50 yd. apart. Even when the front trenches were shifted back behind screens of defensive points, constant guerrilla warfare continued to be waged between the detachments opposite each other. The need for trench artillery was soon felt, and was supplied by a new class of weapon. The original trench mortars had only a very short range, and, as they had therefore to be kept close up to the front trench, the loss of life among the detachments was heavy. Later, longer-ranging trench mortars were introduced, which could be posted relatively far back, and were available for firing on our own front trench if the enemy broke into it.

Trench ordnance on wheeled mounts was used to some extent as accompanying artillery, especially the later pattern of the German light trench mortar, which was fitted for direct as well as for high-angle fire. But the excessive weight of the ammunition renders trench mortars unsuitable as substitutes for guns of accompaniment.

Wire-Cutting.—Very early in the war it became necessary to find a means of destroying, or at least cutting lanes in the strong barbed wire entanglements which covered the whole front. At the period of the autumn battles of 1915, this was done on the British front by the shrapnel fire of field guns. This was effective for wire-cutting only up to about 1,800 yd.; within that range it was found that lanes could be cut through a belt of wire 8 yd. deep with an expenditure not exceeding 10 rounds per yd. of front. Later on, thick steel barbed wire came into use, which could not be cut by shrapnel bullets; moreover, the process of wire-cutting with shrapnel required precise and deliberate shooting, and had usually to be carried out on the day before the attack, thus forfeiting the advantage of surprise. Howitzer H.E. shell with ordinary fuzes proved useless, as they made craters into which the network of wire fell back, making a worse obstacle than before. In 1916 medium trench-mortar shell with instantaneous fuze came into use; these shell made a crater not more than 6 in. deep, and blew away the wire from a circle about 5 yd. in diameter. But trench mortar ranges are very limited and it was not till the instantaneous fuze was adapted to H.E. shell for field guns and field howitzers that the range at which wire could be cut was increased to 4,000 yards. The French used the 75-mm. field gun, while the British mostly used the 4·5-in. field howitzer. As an alternative to the instantaneous fuze, a percussion fuze giving a slight delay action was used with H.E. shell for wire-cutting, the object being to burst the shell on the upward branch of its trajectory after impact, within a yard or so of the ground. Some success was attained with this method when the ground was hard and the angle of impact small, so that the shell did not tend to bury itself. Wire-cutting with H.E. shell is a much quicker method than with carefully adjusted shrapnel bursts, provided that a sufficient volume of fire is obtainable (*see* section EFFECT *supra*).

Counter-Battery work is the attack of artillery by artillery with the object of destroying the material and inflicting disabling casualities, or at least of neutralizing enemy fire for a certain time. In spite of the results achieved in locating enemy guns by aircraft, flash-spotting, and sound-ranging, counter-battery work throughout the war generally failed to destroy them and their detachments, or even to silence them permanently. However, when a battery was located it was usually possible to neutralize it, that is, to stop or much reduce its fire, so long as fire upon it could be kept up.

If a battery exposed itself in the open within range of artillery in position it was destroyed in a few minutes. Therefore batteries used concealed and camouflaged positions with overhead cover proof against field artillery. If such a position was located the battery was soon shelled out by the 6-in. and heavier howitzers, but it was rarely possible to destroy the guns without an

undue expenditure of ammunition. The usual result was that the gunners retired a few hundred yards (if they had no deep dugouts) till the shelling was over, and then came back to their guns. If they were shelled again they shifted their guns to another position. The ground in front of Vimy Ridge was a mass of positions from which batteries had been shelled out, and it was reckoned that one position in four was occupied. The British and the French used to repair abandoned positions to encourage the enemy to go on shelling them. Flashes were fired from dummy positions for the same purpose. "Silent" positions, from which the guns were not allowed to open fire till active operations began, were rarely located.

The Germans were fairly successful in neutralizing batteries with gas shell; concealed artillery positions, being usually in hollows or woods, are specially vulnerable to gas attack. If such a position be thoroughly drenched with persistent gas it becomes untenable, since men cannot work in gas-masks for a prolonged period. In future, flashless powder will make it still more difficult to locate concealed artillery positions.

III. The Break-through

During the three years 1915, 1916 and 1917 numerous attempts were made to break through the opposing line, the most notable being the German attack on Verdun. All these attempts failed; the less unsuccessful of them resulted merely in the capture of an unimportant strip of ground at a heavy cost. A discussion of the reasons for these failures would be beyond the limits of this article. From an artillery point of view it is more important to consider the method of attack which was finally evolved. The two leading principles are the following:—

(*a*) *Surprise.*—This implies the rapid and perfectly timed concentration of artillery and infantry units in the area of the attack, so that they arrive just when they are wanted. If, as is probable, the result of the attack is that the enemy's line is not broken, but is only bent back, successive surprise attacks are made by shifting the weight of the attack quickly to other points which may be 50 or 100 m. distant, so as to form salients in the enemy's line, which are then "pinched out" by attacking them from both flanks. This, at least, is the obvious course; and, because it is so, it may not be the best one. In some cases a commander may decide that he has a better prospect of surprising the enemy by renewing his attack on the original point. Success depends principally on an organization which enables guns and men in large numbers to be placed in readiness for action in any selected area of attack either without the enemy's knowledge, or so quickly that he has no time for counter-preparation.

(*b*) *Wide Front.*—It is useless to make a narrow gap in the enemy's line, commanded by his guns from both sides. It must, roughly, be wide enough to allow for 10 m. of shelled ground on each side, and a 20 m. passage down the middle; that is, about 40 miles. The Germans in March 1918 attacked on a 50 m. front.

Concentration of Artillery.—The first step is to prepare for the concentration on the front of attack of a sufficient number of guns. Normally the line is held by about one gun to 30 yd., including field, medium and heavy. For an attack, this number must be at least trebled.

The Germans, in their great attack of March 1918 on the 50 m. front from Monchy to La Fère, had the following, counting normal establishments only:—

1 field gun per 19 yd. of front
1 field howitzer per 57 yd. of front
1 medium howitzer per 128 yd. of front
1 heavy gun per 128 yd. of front
1 heavy howitzer per 256 yd. of front
1 superheavy howitzer per 512 yd. of front.

This alone amounts to one gun per 11 yd. of front; but in addition to this the four-gun field batteries were reënforced, as far as possible, by adding two guns from reserve. The extra guns were not horsed and the gunners were provided from personnel on the spot.[1] There were also a certain number of miscellaneous guns and a very liberal equipment of trench ordnance. Altogether it may be estimated that the Germans, in this attack, had one gun per 9 yd. of the whole front attacked; but since the attack was pushed home only on alternate sections of this front the concentration of gun-fire on the real fronts of attack was much heavier than these figures imply, as explained below.

In the still more highly developed artillery attack of May 27 1918 on the Chemin des Dames the strength (according to Col. Bruchmüller, who was responsible for the arrangements) was—

1 field gun per 26 yd. of front (*not* including about 30 batteries told off as accompanying artillery),
1 field howitzer per 47 yd. of front,
1 medium howitzer per 99 yd. of front,
1 heavy howitzer per 156 yd. of front,
1 medium or heavy gun per 200 yd. of front,
1 superheavy gun or howitzer per 1,126 yd. of front, or
1 field piece per 17 yd. and
1 medium or heavy or superheavy piece per 49 yd.

In the aggregate 1 piece per 12 yd. irrespective altogether of accompanying artillery, additional guns, and trench mortars.

In the battle of July 15 1918—the last German offensive—the trench-mortar strength was approximately one per 30 yd. for a considerable frontage, and locally as much as one per 10 or 12 yd.

Positions for Artillery.—Assuming that, for an attack, the artillery of a front, normally one gun per 30 yd., has to be increased to one gun per 10 yd., positions have to be prepared for the reënforcing guns. A certain number of spare positions with gun emplacements protected by overhead cover will already exist as part of the equipment of the front, but it is rarely possible to provide labour on such a scale that a defensive front is always kept ready to be used as an attacking front.

If it be possible to bring up the whole of the reënforcing guns during the last night before the attack the preparation will consist principally of marking out gun positions and roads to them, and laying telephone cables to them and to the observing positions. But even with motor equipment the concentration of the whole movement of the troops into one night imposes such a strain upon the transport that it will usually be necessary to spread the movement over three nights, and in this case efficient camouflage must be provided for the guns which arrive before the last night.

[1] They were intended only to take part in the bombardment and not in the advance which followed.

The following table, from the *Revue d'Artillerie* of May 1921, shows the densities of artillery strength in certain French battles of 1915-7:—

Yards of front per gun.

	1 field gun per	1 medium or heavy gun per	1 medium or heavy howitzer* per	1 medium or heavy gun or howitzer per	1 super-heavy piece per
Champagne, Sept. 25 1915	36 yd.	66 yd.	133 yd.	44 yd.	—
Somme, July 1 1916	36 "	50 "	68 "	29 "	121 yd.
Aisne, April 16 1917	22 "	45 "	59 "	26 "	255 "
Verdun (Mort-Homme battle) Aug. 20 1917	20 "	—	—	—	—
Malmaison, Oct. 23 1917	18 "	—	—	—	—

*The French had no field howitzers.

The French "Offensive Instructions" of Oct. 31 1917 lay down a scale for the first-class offensive battle of about

1 field gun per [illegible] yd.
1 medium or heavy piece for demolitions per 30 yd.
1 " " " " " counter-battery per 35 yd.
Superheavy pieces approximately at 1 per 170 yd. (plus 1 piece of trench ordnance per 30 yd., except in parts of the front reserved for tank action).

Registration.—The reënforcing guns must be able to open fire at zero hour. Usually the batteries belonging to the front register their targets for them beforehand, the registration being spread over several days so as not to attract special notice. But calibration, study of atmospheric influences, and surveying[1] have latterly been so thoroughly applied that it may be possible, in future, to rely upon opening effective fire by map without ranging. This again requires thorough preparation, which is possible when an attack is planned beforehand. So far as can be foreseen, there is no prospect of dispensing with ranging when the troops are on the move.

Conduct of the Attack. Bombardment.—In the great trench battles of 1916 and 1917 it was customary to begin with a bombardment of the enemy lines lasting a week or even more. This was fatal to surprise action, and in 1918 the preparation consisted of some six hours or less of "intense" bombardment, every gun firing at its highest rate. The use of tanks may in future enable this bombardment to be shortened, as will be seen. The Germans pressed their great attack, of March 1918, only on alternate sectors (of about 3,000 yd.) of the British line, trusting to envelop the intermediate sectors. They were thus enabled to concentrate nearly the whole of their guns on half the total frontage, so that they had roughly one gun firing on every 5 yd. of the front actually attacked.

A reasonable estimate of the ammunition required for a six hours' intense bombardment per mile of front seriously attacked is 50,000 rounds field gun ammunition, 10,000 field howitzer, 5,000 6-in. howitzer, 2,000 6-in. gun, 500 heavy howitzer, and 200 rounds superheavy howitzer. If the attack presses forward without a check for three days from the start, then at least 50% more will be required on the second day, and the same on the third day if the enemy is reënforced; at any rate it would be unwise to begin an attack without double the above amount in hand. If the attack is seriously checked the intensive bombardment will have to be repeated and a fresh start made. These figures give a fair idea of the scale on which guns and ammunition are used in modern warfare.

The reason for this vast expenditure of ammunition is that the bombardment is not confined to the front of the position attacked—the front zone, as explained above, is a thinly held system of outposts—it is directed mainly on the real defensive zones and centres in rear. Targets such as railway stations, bridges, and road junctions as much as 10 m. behind the front have to be bombarded by the long-range guns and howitzers.

Influence of Tank Action on Bombardment.—In the autumn of 1918 the tanks achieved such success in breaking through defences which had not previously been bombarded that it is considered that in some cases, provided that the ground is favourable for tank action, it may be possible to shorten the *preliminary* six-hours' bombardment to half-an-hour, or even to dispense with it altogether, and to trust to the creeping barrage to protect the advancing infantry and tanks (British Field Service Regulations, 1920, Part II., para. 118 [6]). When this method is employed all guns other than those firing the creeping barrage will concentrate on important points behind the enemy's front simultaneously with the launching of the attack.

This is a new method of procedure, in which our present experience is not sufficient to enable us to forecast the best course of action with any confidence. The regulation quoted above is cautiously worded, and does not imply that the use of tanks will render bombardment unnecessary. Even if the tanks are expected to succeed in rushing the first and second zones of the enemy's defences, they will certainly experience increased resistance as they penetrate deeper into the position. In future warfare tanks will not be the only motor vehicles on the battlefield. The mobility of the defender's motor guns and motor infantry, both on and off the road, will enable him to bring up reënforcements far more quickly than was the case in 1918. Although the attack may be launched without any previous bombardment, it will still be necessary to deliver a heavy fire on targets behind the enemy's front as soon as the attack is disclosed. It will not be enough to bombard railway stations and road junctions if the defender's motor troops are independent of railways and roads. Therefore this fire will presumably be not so much a bombardment of fixed points as fire for effect, directed by aeroplane observation, upon the defender's reënforcements.

So far as can be judged the amount of ammunition required for an attack will be increased rather than diminished, in view of the scattered targets presented by motor troops.

The Infantry Attack.—As soon as the "intense" bombardment has done its work on the outpost zone and the first line[2] the infantry advances, screened by a creeping barrage, preceded by tanks, and closely followed by guns of accompaniment. The bombardment is "lifted" from the first line to reënforce that on the second line; as soon as the infantry have taken the first line fresh waves of men pour through them to attack the second line. When the second line is taken the field artillery of the attack pushes forward by echelons to positions in or near the first line. Later on the medium and heavy artillery push forward.

It is not to be expected that the infantry will be able to advance on a continuous front. After the thinly held outpost system has been rushed progress is by "infiltration." Wherever a weak point is found the infantry pour through it, and the advancing streams of men, fed by the local reserves, spread out to right and left and envelop the defensive points that still hold out. Tanks are here invaluable in leading the streams of riflemen, in "rolling out" barriers of barbed wire, and in rushing the centres of defence. It is the involved and complicated nature of this warfare which prevents the main body of the artillery in rear from supporting the infantry in the series of local combats which characterize the advance through the trench system, and which renders it necessary to provide the infantry with guns of accompaniment.

The process of infiltration outlined above is apt to produce irregular salients in the advancing line, which the artillery in rear find it difficult to protect by barrage, and which are therefore the more exposed to counter-attack. On this account it was the practice, at one time, to limit the objective—that is, to fix a line beyond which the troops were not to advance, so that when this line was gained they should present a continuous front, protected by artillery fire, from which a further advance could be made. This system led to a great waste of opportunity. It may still have to be adopted on occasion; but the modern tendency is to gain every possible foot of ground, and to provide reserves on a scale sufficient to "feed" the salients so that they can spread out laterally and "pinch out" the ground between them which is still held by the enemy. That is, every salient must become an offensive, not a defensive, feature. Without artillery support these offensive tactics would hardly succeed against the defender's "strong points," which are not merely fire-trenches facing the front, but miniature forts prepared for all-round fire. It is necessary, therefore, that in addition to the guns of accompaniment part of the artillery in rear should press forward boldly, so as to keep in touch with the infantry and be able with the assistance of aeroplanes or of their own reconnoitring patrols to direct a heavy fire on any defensive work which still holds out.

The action of the artillery in the attack may be summed up as follows: the bombardment weakens the defence and the barrage protects the attack. The guns of accompaniment support the attack so long as the enemy continues to retire, offering only slight resistance intended to weaken the attack. When resistance becomes serious the divisional field artillery must be in position and in communication with the infantry, so that

[1] The position of one gun in each battery (or other unit) is fixed *exactly* by survey and marked both on the map and on the ground before the guns arrive.

[2] The word "line" is used in this description because no other accepted military term is available. In reality modern defensive systems consist of chains of detached works or trenches, supporting each other by their fire. The only continuous feature which marks a defensive zone is the belt of barbed wire entanglement, and this itself is irregularly traced.

they can support it in local combats. If the resistance becomes obstinate and beyond the power of infantry and field guns to overcome, the bombardment by the heavy artillery must be renewed.

These tactics are repeated as each successive line, or defensive zone, is encountered. The process can be repeated indefinitely so long as the supply of men, guns, and ammunition can be kept up, provided that it is possible to convey them to the fighting line. The latter has proved a very serious difficulty in the past, and has perhaps been more instrumental than any other cause in bringing great attacks to a standstill. It must be overcome by the work of the engineers in repairing roads and railways, and by the provision of improved cross-country vehicles.

Artillery in Defence.—Whether defence in the hitherto accepted sense is or is not the form of resistance best suited to modern conditions is a question which lies outside the scope of this article. For the present purpose it is assumed that the ground occupied is to be defended in the literal and tactical sense.

In the ordinary defence of a position the method of meeting an attack varies according to the degree of certainty with which the enemy's intentions have been anticipated, and the amount of preparation which it has been possible to make.

If the defender is fully prepared for the attack, and has massed his artillery to meet it, then he can reply to the initial "intense" bombardment with a similar bombardment, which will certainly render the attack ineffective.

If he knows when the attack is to be launched, but has not been able to reënforce his artillery, he can still put down a preventive barrage, just before "zero" hour, on the enemy's lines. This will weaken the attack, and may delay it.

Even if the defender has had no warning, and is unable to oppose gun for gun to the attack, the mobility of motor artillery should, in future, enable him to reënforce his artillery (provided he has guns available elsewhere) within two days at most. But the enemy will probably provide against this by making a holding attack on a very wide front, or on several fronts. The defender will be uncertain as to which of these is the real attack, and will be afraid to take any guns out of the line. He must then depend upon his general reserve for the artillery reënforcements which he requires.

We will consider the case of a section of an entrenched front, held with the normal proportion of artillery (one gun to 30 yd.), attacked by surprise by a concentrated force (one gun to 10 yd.). It is clear that the attacking infantry must come out into the open when they advance, and that they are then exposed to artillery fire. Putting down a shrapnel barrage at 10 seconds' notice on the enemy's front line, and bringing it back over one's own lines when necessary, is of course part of the regular routine of trench warfare. But the attacker counts on destroying or neutralizing the guns of the defence by his bombardment and counter-battery fire, and he is likely to succeed to a great extent as regards batteries which have previously disclosed their positions by firing. It is therefore necessary to have "silent" batteries in the line, that is to say, batteries which, ordinarily, are never allowed to fire except on occasions when visibility is bad, and then only under precautions against sound-ranging. The normal expenditure on a divisional front may be 1,000 rounds a day, or less on quiet fronts, and this allowance can be fired by a small number of batteries, so that there is no difficulty, other than the administrative one, in keeping half the guns of a front in silent positions in reserve to repel an attack.

Another necessary precaution is the provision of deeply buried telephone cables, proof against bombardment by heavy artillery; and these must be laid not only to the ordinary gun and observing positions, but also to the positions in rear to which the artillery may have to retire.

As soon as the attacker begins his "intense" bombardment the guns of the defence reply with a similar bombardment, necessarily on a scale corresponding to their smaller number. "Silent" batteries take part in this, since the smoke of the bombardment will conceal their positions. When the infantry attack is launched, then, assuming that the defender has still a fair number of batteries effective, as soon as the call is made upon them the field guns and trench mortars of the defence put down a heavy barrage on the enemy's front-line and communication trenches. Medium guns and field howitzers barrage probable assembly points, while medium and heavy howitzers bombard the attacker's gun positions, so far as these have previously been disclosed. Since the defence has been weakened by the bombardment it is probable that the attacker will capture the forward zone. It takes one gun per 20 yd. to make a heavy barrage; the defender starts with only one gun per 30 yd., and may be reduced to one gun per 60 yd. at the end of the "intense" bombardment. Of these at least a third will be firing on the attacker's guns and communications, so that the defender's barrage will presumably be too thin to stop a determined attack, though it will cause a considerable number of casualties.

For this reason the defender will probably elect to use a partial barrage, that is to say, a barrage of effective density, covering only part of his front, the remainder being protected by machine-guns and trench mortars. If his telephone communications are thoroughly reliable he may be able to control this barrage so as to put it down, at a moment's notice, in front of any part of his line that is attacked. Each battery will then have, say, three alternative sets of barrage orders, so that the whole barrage can be put down on any one of three sections of the front. But this method is so complicated and so liable to break down that few commanders would care to trust to it.

As the attack gains ground the defender endeavours to keep his counter-barrage on the leading troops of the attack, and behind his retiring infantry; but owing to the inevitable breakdown of communications while the infantry are on the move it is not likely that this ideal will be completely achieved. When the defenders retire from the second zone of defence the attack will be getting within rifle range of the defender's field guns. The defender cannot afford to lose the whole of his field guns, but it is desirable that some of them, say one-third, should remain in action till the enemy is within 500 yd. of them, as they will cause heavy loss by their point-blank fire. If well supported by the guns which have already retired they have an excellent chance of getting away. As the retirement continues the medium and heavy pieces have to withdraw to the positions prepared for them in rear.

There are many details, such as the support of local counter-attacks and the protection of "strong points" which have held out against the attack, which cannot be entered upon here. Speaking generally, the object of the defender when attacked by a greatly superior force is to maintain an orderly retirement, with his line bending back but never breaking, taking heavy toll of the attacking infantry at every stage of their advance, until the attack is sufficiently weakened, or the defence sufficiently reënforced, to enable the defender to launch a general counter-attack.

Enfilade Fire.—It has often been suggested that the best artillery defence is that afforded by the oblique and enfilade fire of guns from adjoining sectors of the front. This theory broke down in practice. During sedentary warfare every division had enfilade sections established in its neighbours' territory, or else had a "call" on some of its neighbours' guns for enfilade purposes. So long as the line was not seriously bombarded these guns were very useful. But when the line was attacked in force it was quite hard enough to keep up communication from front to rear within a divisional area, and it proved impossible to direct the fire of the guns of other divisions. These often joined in on their own account to help a neighbour when they could see what was going on, but their assistance could not be relied on as part of the scheme of defence.

Within the divisional front the method of enfilade fire at short ranges is constantly employed; every one of the detached trenches and other works which constitute a defensive zone should be enfiladed from works in rear of it, and the approaches to it should be swept by oblique fire. This duty is chiefly performed by machine-guns, but it is advisable, when possible, to provide the batteries in rear with extra emplacements from which guns can fire obliquely or even across their front.

Defence against Tanks.—In describing the defence of an entrenched position, no mention has so far been made of tanks, although the use of these is now one of the most important features of the attack. And this is because the best method of dealing with attacking tanks is still a matter of speculation.

Tanks advancing against a position are screened from the aimed fire of distant artillery by the barrage which precedes them. If ordinary field guns are concealed in the front line to destroy them, these are generally destroyed themselves by the bombardment. Some tanks may be hit by the defender's barrage, but this is likely to be either thin or partial. At a later stage some of the tanks will be hit by those field guns which remain behind till the attacking infantry are within 500 yd. of them. The uncertainty of defence by mines and by ditches has been shown by experience. Tank-stopping rifles and tank-stopping machine-guns are effective against the present tanks, but those used in the next war will be proof against anything short of a gun.

It is often assumed that attacking tanks will be engaged by the tanks of the defence. But when a position is subjected to a fully organized attack the latter will not find it easy to do this. If kept well up to the front in readiness they will be destroyed by the bombardment, to which they offer large targets. If kept some 3 m. in rear till the attacking tanks appear, they will, even if their movements be correctly timed, have to pass through the attacker's bombardment and barrage, and possibly through their own barrage. Moreover, the tanks of the defence are presumably fewer in number than those assembled for the attack, so that even if they arrive in time they will be outmatched.

The best solution of the difficulty would appear to be the provision of special anti-tank guns, large enough to put an armour-piercing shell into a tank, and small enough to be provided with strong cover. A light mountain gun, capable of being divided into man-loads, would be suitable for the purpose. These guns might be in dugouts some 400 yd. behind the front line, where they would not be subjected to the full violence of the bombardment. When this was lifted from the front line preparatory to the assault, the anti-tank guns would be put together and run up on to platforms level with the tops of the trench parapets, giving them sufficient command to see the attacking tanks as they charged the front line.

A regular defence in depth by anti-tank guns would have to be provided for, additional anti-tank guns being sited behind each successive line of defence, as well as in "strong points."

These anti-tank guns would have to be "silent" guns, at least so far as their own firing emplacements were concerned. Their provision, on a scale sufficient to stop a tank attack, would involve a considerable addition to the artillery of the defence. For even if the infantry guns of accompaniment were utilized as anti-tank guns, there would not be enough of them. Infantry guns are required at the rate of one per 100 yd. of the front of the attack, or at most 16 to a division; while if a division holds 3,000 yd. of entrenched front it will require three lines of anti-tank guns sited 200 yd. apart, that is 15 in each line, or 45, besides some 15 for "strong points." This calculation shows that 60 anti-tank guns per divisional front are required, or about one per 45–50 yards.

It may be suggested that the anti-tank guns of the first line could withdraw to the second line, and then again to the third line. But since they have to remain in position till the attacking infantry have almost reached them, in order to deal with the tanks, there would appear to be little chance of withdrawing the guns, although the detachments may be able to escape.

The expenditure of men and material for a special purpose which the above scheme involves is not to be undertaken lightly. But it has become manifest that attacking tanks are safe from distant artillery, and must be engaged by guns on the spot. Therefore these guns will have to be provided; and, so far as our present experience extends, the provision of numerous small guns in the trench area seems to be the best answer to the menace of the tank attack

IV. The Phase of Exploitation

In France, in the latter half of 1918, after four years of trench fighting, the retreat of the invader brought the combatants into the open once more, but under changed conditions. The artillery had increased in numbers relatively to the infantry; their ammunition supply admitted of a greatly increased volume of fire, and their range had been extended. Mechanical traction, even for field artillery, had to a great extent come into use, especially in the French army, and medium, heavy and even superheavy ordnance were able to accompany the troops in the field.

Under such conditions the troops had to adapt themselves to a new method of warfare. The pre-war battery commanders, experts in mobile warfare, had been replaced by others whose training had begun in the trenches. Few of the officers and men had any knowledge of mobile warfare as thought and practised before the war, and even these found that they had to learn their work afresh.

Moreover, owing to the strain upon the munition factories manufacture had come to be limited to projectiles of simple design suited for mass production, and shrapnel had disappeared from all but the field-gun equipments. In the French army, even these had only 5% of shrapnel. the rest being H. E. shell

The mobile phase did not last long enough for the employment of artillery in a war of masses to be thoroughly studied The conclusions arrived at cannot be regarded as final, and are subject to possible modifications due to the more extensive use of tanks, motor artillery, and motor infantry.

Horse Artillery.—The old methods of manoeuvre are not applicable to a war in which the line of battle is continuous, with no flanks. Whatever the general procedure selected by the attacker, or pursuer, he will keep close touch with the defender's line, and maintain pressure on it at all points so as to deny him freedom of manoeuvre. The object of the pursued is to break away from the pursuer, and to lose touch with his troops, so as to regain freedom of manoeuvre in order to counter-attack, to take up a defensive position, or both. In this nature of warfare horse artillery are of great value. (In the coming age of motor artillery, the term "horse artillery" must be understood to mean a more mobile arm than the divisional field artillery, capable of working with the "cavalry" of the future, however that arm may be transported.) The lessons of the first phase of the western campaigns and of the Palestine campaign of 1918 still hold good.

The Attack.—The result of the continuous line of battle is that all attacks are, tactically, frontal attacks. Within the limits of an army corps or divisional frontal attack there will be local flank attacks; thus it is often easier to envelop a strongly held locality than to take it by direct assault. But these are minor operations which concern the trench mortars, the guns of accompaniment, and the gun-carrying tanks rather than the main body of the artillery.

Intimate coöperation of gun and rifle is more necessary than ever, owing to the increased fire-power of the defence afforded by the machine-gun. The breakdown of *liaison par le bas* in the opening phase of the war has already been referred to; in the concluding phase this was still more marked, and the French especially complained that their artillery misused the increased range of their field gun by keeping far in rear of the infantry, where communication with them was impossible, instead of pressing forward to find out what was going on. But even if *liaison* is so far effective that the artillery know when the infantry is checked by fire, it does not follow that they will be able to discover the source of the fire. Possibly the infantry may not know themselves. Aeroplanes may be of great help both in locating it and in promptly conveying the information to the supporting artillery. It is even conceivable that battery commanders will direct the fire of their guns from aeroplanes. But the possibilities of "liaison by the air" are still too vague to count upon.

The Barrage.—Since, under present conditions, the artillery cannot always give the infantry direct support by killing the

troops that are firing on them, it is the more necessary that they should at least screen them from aimed fire. Therefore, the artillery barrage has become a feature of mobile as well as of trench warfare. Tanks also require to be screened hy a harrage, although this, since it is not required to destroy opposition, may consist of smoke shell, of which a relatively smaller number suffice to create an opaque veil. Therefore, in a future attack, the artillery must be on hand so that they can be got into action at short notice, ready to form a barrage at once. But the artillery of the normal divisional establishment will barely suffice for the purpose. If it is a smoke harrage that is required, this is preferahly fired by the divisional field howitzers which are the most suitable weapons. These are provided as a rule on the scale of about 16 pieces per division. If, then, the division attacks on a front of 1,600 yd., this gives only one field howitzer per 100 yd., and at their highest rate of fire (about 10 rounds a minute for short periods, or 100 rounds an hour) they will not be able to form a smoke barrage to cover the whole divisional front, unless the weather conditions be exceptionally favourable. Similarly, for an offensive barrage of shrapnel or H. E., which requires one gun per 20 yd., the 72 field guns and field howitzers of a pre-war division would barely suffice to cover its attacking front, leaving none available for bombardment and counter-battery work. The divisional artillery must therefore be reënforced for an attack, as in trench warfare, though not necessarily to the same extent.

This reënforcing artillery will be taken, in the first place, from reserve formations. Presumably the highly mobile army reserve field artillery will he drawn upon first, and then the artillery of the divisions in reserve. It may even be necessary to take field artillery from other divisions in the fighting line. In the days of horse-drawn artillery this would have heen a dangerous expedient, but with motor artillery capable of covering 50 m. a day the objections are less serious.

Observation of Fire.—When both forces are on the move, there can have been no previous registration of targets. Therefore the medium and heavy artillery, which engage long-distance targets, must use aeroplane observation so far as available. Firing hy the map is in mobile warfare a last resource, as there is no opportunity for the survey work characteristic of trench warfare and of the preparatory phase of the hreak-through battle. The mastery of the air, in order to enable ranging aeroplanes to do their work, is of the highest importance.

Change to Trench Warfare.—Mobile warfare is liable to turn into trench warfare at any moment; the retreating force, if not vigorously pressed, may have time to entrench a position. And even the advancing force may find it expedient to halt and protect itself hy entrenchments when the strategic centre of gravity shifts to another part of the line or even another theatre of war. Therefore an advancing or retreating force must have at hand, so as to be available at short notice, the whole armament necessary for trench warfare, from heavy howitzers on railway mountings down to trench mortars.

The Defence.—A defensive position in mohile warfare differs from a regularly entrenched position principally by the weakness of its passive defences. Belts of barbed wire, deep trenches and dugouts, and armoured machine-gun emplacements cannot be improvised; they require time, lahour and material. As regards offensive power, the chief drawback of an improvised position is its weakness in long-range artillery fire, due to the fact that firing by the map requires careful preparation, including surveying and mapping from aeroplane photographs. Another weak point is the difficulty of providing reliable communications, since deeply laid telephone-cables are not availahle.

As ahove mentioned, the position consists of a system or network of localities, supporting each other hy their fire, and distributed in depth as far as the strength of the force allows; thus a strong force may hold a zone 3 m. deep, with the positions nearest the enemy held just strongly enough to oblige him to deploy. A few horse artillery or mountain guns, supported by machine-guns, afford a sufficient volume of fire for this purpose. As the attacker penetrates into this network of small positions, he finds it increasingly difficult to maintain a continuous line, with or without a barrage in front of it, and he is exposed to counter-attacks, especially from tanks which have been concealed behind cover. If he attacks *en règle* with an intense bombardment and complete harrage, he may find that he has wasted his time and ammunition on a skeleton force. His safest course is to bombard and assault each strong point in turn. But the defender will avoid the choice of conspicuous localities as strong points; an angle of a hedge affording a field of fire of only 100 yd. is better than a clump of trees on a hill. Many of the strong points will he so inconspicuous that they will have to be located by the advancing infantry and tanks before any considerable volume of fire can be hrought to bear on them hy the artillery in rear. In principle, the defender's methods are the same as those described earlier in this article, but the absence of the successive definite zones of defence allows of greater flexibility, especially as regards counter-attacks. The attack on an entrenched position is to a great extent a prearranged operation hased on positive and detailed information. But when the attacker penetrates into the advanced works of a strange position, unfamiliar to him except in so far as the natural features of the country are shown on the map, he ventures into the unknown, and the advantage of surprise attack rests with the defender, if he is hold enough to avail himself of it.

On the other hand, the successful defence of a position in the open unfortified country requires a nice balance of suhordinate initiative and higher control, and therefore a degree and quality of efficiency that are not always to be found in a retreating force. (H. A. B.)

V. Organization

Before the World War the artillery of the military Powers was organized on the following general lines: Cavalry division, one horse artillery battery per brigade of three regiments, each of 600 sabres. Infantry division of 12 battalions, six field guns (including field howitzers) per battalion of 1,000 rifles. A British division had also one battery of medium guns. Army Corps of two or more divisions, 6-in. guns and howitzers (no fixed scale), and the divisional artilleries. In the French army, a proportion of the field guns which elsewhere were assigned entirely to divisional artilleries was reserved under corps control as "corps artillery." Army of two or more army corps, all mobile guns and howitzers of calibres above 6-in. (few existed) and a siege train when required.

Proportion of Guns to Rifles.—The proportion of six field guns per 1,000 rifles was found satisfactory, as a normal scale, throughout the war, but extra field guns from army reserve had to be added for anything larger than an army corps operation. Opinions differ as to the strength at which this reserve should he maintained; it may possibly be fixed at 25% of the divisional artillery.

For trench warfare, the divisional field artillery had to he supplemented by the addition of pieces effective against field entrenchments. These included medium howitzers, notably the 6-in. howitzer throwing a 100-lb. shell, and medium and heavy trench mortars.

Battery Organization.—Before 1914, field artillery had in most countries been organized in batteries of four guns. Great Britain (for her regular army), Germany, Austria-Hungary and Italy[1] however, kept to the old six-gun battery. The Russians had a unit of eight guns, which could be used as two four-gun batteries. The four-gun battery is tactically more efficient; it admits of more intensive fire-direction, and is easier to lead and to conceal. Moreover, a six-gun battery rarely has occasion to use its full fire-power of 20 rounds per gun per minute, and its guns are not worked to their full capacity; better value, gun for gun, is obtained from the four-gun unit. In Great Britain, on the outbreak of war, all the batteries of the new army were raised as four-gun batteries, as were already those of the Territorial Force. But in 1916 the British army reverted to the six-gun organization; the reason given being the impossibility of providing a full battery cadre of five officers for every four guns. But it is an open question whether that cadre as conceived in Great Britain is not itself unnecessarily large. The French have only three,

[1] The Italians were about to introduce the four-gun battery in proportion as the Deport gun replaced the Krupp.

and in their batteries many of the duties which the British consider can only be done by an officer are performed by warrant or non-commissioned officers. The six-gun battery in peace, on the other hand, makes for economy and it is doubtless on this ground that the British authorities have decided, since the war, to retain it for field batteries.

Distribution of Field Guns and Field Howitzers.—In most armies, the divisional artillery consists approximately of 75% of field guns and 25% of field howitzers. It is a question whether the howitzers should be organized as a separate brigade, or whether each brigade should consist of three batteries of guns and one of howitzers. (It should be explained that the use of the term "brigade" to mean a group of three or four batteries of artillery is peculiar to the British army. Other nations restrict this term to the higher formations, commanded by a general officer, the unit corresponding to the British "brigade" being designated *groupe*, battalion, *Abteilung*, division, etc.)

The Germans, in 1915, distributed their howitzer batteries among the gun brigades, but later on, they reverted to separate howitzer brigades in the proportion of two gun and one howitzer brigade per division, the three batteries of each being all on the four-gun basis. The British broke up their howitzer brigades and distributed the batteries in 1916, and retained these mixed brigades to the end of the war. The difference in the training of the men is slight, and is concerned principally with the extra complication of the divisible charge used in howitzers. Now that it is proposed in most armies to use half-charges and super-charges as well as normal charges for long guns also, this difference is tending to disappear. During trench warfare, a howitzer brigade was never used as a fire-unit; its batteries were distributed along the divisional front. In mobile warfare, there are many occasions when the fire of field guns requires to be supplemented by that of field howitzers, and few, if any, when a field howitzer brigade would be used alone. Assuming that the field howitzer is a light piece of the same mobility as the field gun[1] it appears that the mixed gun and howitzer brigade, consisting of three batteries of guns and one of howitzers, is the better organization of the two.

Fighting Organization of Artillery during the War Period.—For the standards of 1914, three types may be taken as representative: the German, the French and the British. Field and heavy field batteries only will be considered.

The German army corps of two divisions possessed 144 field guns and field howitzers, and 16 heavy field (6-in.) howitzers. Only the latter-named were corps troops, all field artillery being divisional. Each division possessed a field artillery brigade of two regiments, each regiment having two *Abteilungen* of three six-gun batteries each. One of the four *Abteilungen* in each division was armed with 105-mm. (4·1-in.) field howitzers, the other three with the 77-mm. field gun. The corps heavy artillery formed a "battalion" of 4 four-gun batteries. In the field artillery, the battery, besides its six guns, possessed nine ammunition wagons, and in all 17 vehicles. The personnel was 150 of all ranks with 135 horses. The *Abteilung* had 480 officers and men, 400 horses and 53 vehicles. The light ammunition column, of which there was one for each *Abteilung*, had 190 officers and men, 180 horses and 24 vehicles. In addition, there was the field artillery component of the less mobile ammunition column allotted to the division. The heavy battery (230 officers and men) in addition to its four guns had eight ammunition wagons and seven other vehicles, with 120 horses in all. The battalion of four batteries numbered 960 officers and men, 520 horses and 80 vehicles. A light ammunition column of 29 vehicles, 270 personnel and 190 horses carried the first reserve and a slow-moving column the second. Heavier artillery, some of which (21-cm. mortar batteries) had for many years been organized for rapid movement, was allotted to armies as required.

The French artillery was divided into divisional and corps artillery, armed uniformly with the 75-mm. gun. The few heavy batteries available were army artillery and there was no light howitzer. The field battery had four guns and no less than 12 ammunition wagons, with six other vehicles. The personnel was three officers and 170 other ranks with 165 horses. The *groupe* consisted of three batteries, with a total of 544 men (including 16 officers), 514 horses and 71 vehicles. The first ammunition reserve was an "artillery ammunition section" of 20 ammunition wagons (half slow-moving) and other vehicles. Each division had a regiment of artillery consisting of three *groupes* and each corps, as corps artillery, a regiment of four *groupes;* there were thus 10 *groupes* or 30 batteries (120 guns) per corps.

The British army in 1914 did not possess the corps organization, and some elements usually under corps control were in this instance divisional, especially the heavy field artillery.

The divisional artillery was under the command of a brigadier-general and consisted of three "brigades" (of three six-gun batteries each) of 18-pr. guns, and one brigade (similarly constituted) of 4·5-in. howitzers, plus one four-gun battery of 60-pr. heavy field guns. The battery had two ammunition wagons per gun, making with other vehicles a total of 20. The battery personnel numbered 200 including five officers, with 174 horses. To each brigade was attached permanently a light ammunition column, consisting of a third ammunition wagon per gun, and 13 vehicles of different sorts for infantry ammunition.[2] In all, the brigade with its ammunition column had 803 officers and men, 764 horses and 102 vehicles. The organization of the howitzer brigade was practically identical, except that its ammunition column did not supply infantry, so that the total of vehicles was smaller, viz. 89. The strength in personnel was 763 and in horses 719. The heavy battery had 19 vehicles including its guns, and possessed an ammunition column of its own, consisting of a third ammunition wagon for each gun and one other vehicle. Thus in all, the unit had 24 vehicles. The personnel of battery and column together was six officers and 192 other ranks with 144 horses. The divisional ammunition column consisted of 113 general service wagons (of which 81 were for artillery ammunition, 18 for infantry and one for special stores), personnel 15 officers, 553 other ranks, horses 709.

A general comparison of artillery strengths in men, horses and vehicles (excluding those allocated to the service of infantry ammunition) shows the following:—

Great Britain (two divs.)
7,640 officers and men, 6,136 horses, 996 vehicles, incl. 152 guns.
France (corps)
7,750 officers and men, 6,737 horses, 943 vehicles, incl. 120 guns.
Germany (corps)
7,830 officers and men, 6,850 horses, 975 vehicles, incl. 160 guns.

(In all the above figures, supply and baggage wagons have been included.)

This organization, designed for mobile warfare, broke down under trench warfare conditions. The organic artillery allotment of the division proved to be too large for normal trench warfare fighting and too small for battle. The army corps itself, as a standard unit, gradually ceased to exist, and was changed into a new form of army corps which—generally fixed in a particular area of the front—constituted a permanent framework, in and out of which different divisions constantly passed from "line" to "rest" and *vice versâ*. The exhaustion of the fighting energy of infantry and of artillery respectively when in the line proceeded at different rates, and the infantry of a division frequently had to be withdrawn and replaced by that of another while its artillery remained in position. The growth of the "dump" system of ammunition supply rendered the elaborate organization of horsed ammunition reserves largely uneconomical. Lastly, the range of guns permitting of artillery collaboration between adjacent divisional sectors—especially for counter-battery work—a common organization for the command of the artillery of several sectors was bound to come into being.

In the British, French and German artillery, accordingly, the divisional field artillery was reduced to a strength suited for a divisional sector in trench warfare; this artillery went in and out of line with its division. The remainder of the field artillery was formed into a mass of "army reserve artillery," the function of which was to double, treble or quadruple the divisional artilleries in a battle area. This reserve, being wholly independent both of the area organization and of the divisional formation, could be brought into action as required and for as long as required. The medium and heavy artillery, similarly, was divided into two portions, but the change was here less obvious, as little or no artillery of these classes had belonged organically to divisions. The one portion was substantially fixed to the area, the other placed in army reserve and used to reënforce the area heavy artillery for battle periods.

The following diagram illustrates the evolution just described:—

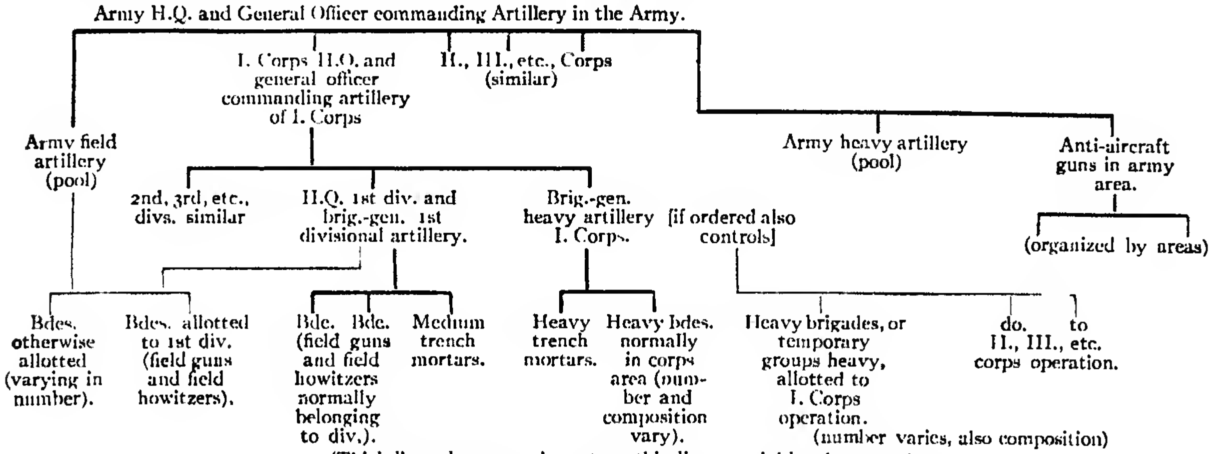
	Medium and Heavy.			*Field.*	
1914	Army (inclusive of artillery taken out of fortresses).	Corps.	(Divisional, where it existed.)	(Corps, where it existed.)	Divisional.
				Army reserve field.	Divisional field.
1917	Army reserve heavy.	Corps heavy (sector).			

[1] The reservation is necessary as some nations have no light field howitzers, and use the 6-in. as the divisional high-angle weapon.

[2] Neither the French nor the German first reserve columns supplied infantry ammunition.

The effective solution that this reorganization provided for the problem of divisional reliefs, and incidentally the necessity for some such solution, are illustrated by the fact that in the prolonged Flanders battle of July–Oct. 1917 the average time spent in line by divisional artillery (which moved in and out with their infantry) was 33 days, while the average for units of the army reserve field artillery was 72 days.

When fully developed—at the end of 1917—the higher organization of the British artillery in France was as follows:—



(Thick lines show organic system, thin lines special battle system)

(At this period the field brigades were composed of three gun and one howitzer battery each; the composition of heavy brigades varied considerably, a "mobile" brigade consisting of two 60-pr. and two 6-in. howitzer batteries, while others contained 9·2 and 8-in howitzers in addition.)

German practice differed considerably from this, in that all artillery in a divisional area was under control of the divisional artillery commander, while in major operations the artillery of several corps together was controlled for the occasion by a "general of the artillery" who was often neither a general officer in rank, nor a permanent member of the army headquarters concerned.

The average strength in batteries of a divisional sector (in the case of the German nine-battalion division) was—the six field-gun and three field-howitzer batteries of the division, and five to seven batteries of medium and heavy artillery belonging to the sector, or, in pieces, 36 light plus 24 heavy (irrespective of trench mortars). Figures have already been given for typical artillery strength in battle (in terms of yards of front per gun).

The return to open warfare conditions in 1918 made further changes, chiefly in the direction of providing divisions with medium artillery of their own and separating what had formerly been "sector" heavy artillery into calibres suitable for incorporation in mobile divisions and calibres best managed by corps headquarters. The Germans made a beginning with this process in permanently allotting a group of one 10·5-cm. gun battery and two 15-cm. howitzer batteries to each divisional artillery.[1] But the best example of artillery organization as conceived in 1918 for purposes of the expected mobile warfare, is that laid down (though never fully carried out owing to the close of hostilities) for the American Expeditionary Force.[2]

The divisional artillery consisted of a brigade of three regiments, two being of field guns (75 mm.) and one of medium howitzers (155 mm.). The field-gun regiments consisted each of two "battalions," and each "battalion" of three four-gun batteries, in all 24 guns per regiment or 48 per division. The other had three "battalions" each of two four-gun batteries, making 24 medium howitzers. Thus, as in 1914, we find 72 guns per 12 battalions or six guns per 1,000 rifles, but the addition of numerous heavy machine guns to the rifle strength makes the proportion of guns, in relation to fighting frontage, somewhat less. Each divisional artillery possessed a battery of 12 medium trench mortars.

The corps artillery (each corps had four divisions) comprised one regiment of medium guns (4·7 in.) and one of heavy guns (155 mm.) both "motorized," as well as four batteries of heavy trench mortars. These artillery regiments were arranged, like the medium regiment of a division, in three battalions each of two four-gun batteries; thus in all, the corps artillery contained 24 medium and 24 heavy long guns. The two regiments formed a brigade.

Army reserve artillery (for an army of five corps or 20 divisions) consisted of four brigades (motorized) or 12 regiments of heavy guns (6-in.), organized as above, and containing in all 288 pieces, and five regiments of field artillery (organized in the same way as divisional field artillery regiments) with 100 pieces.

Lastly, under G.H.Q. direct was the Railway Artillery Reserve, consisting of 42 batteries (*i.e.* pieces) grouped in "battalions," regiments and brigades.

Neglecting the last item, then, we find for an army of 20 divisions, about to be engaged in offensive mobile warfare and counting 201 battalions of infantry and pioneers and 120 regimental and divisional machine-gun companies:—

Field guns.	Medium howitzers.	Medium guns.	Heavy guns.
240 batteries divisional, 120 batteries in army pool.	120 batteries in divisional artillery.	120 batteries in corps artillery.	120 batteries in corps artillery, 72 batteries in army pool.
= 1,440 pieces	= 480 pieces	= 480 pieces	= 768 pieces

Total batteries 792; total pieces (excluding Railway Artillery and trench mortars) 3,168; or roughly 10 guns per 1,000 of infantry, pioneer, and machine-gun establishments, of which $4\frac{1}{2}$ belong to divisional, 3 to corps and $2\frac{1}{2}$ to reserve artillery.

In the British and American examples quoted, an artillery staff under a brig.-gen. or maj.-gen. is provided at the rate of about one per 90 guns (or including the field artillery pool one per 100). The German artillery staffs were in a smaller proportion. This question of higher artillery commands is still an open one, but it is clear that under modern conditions no reversion is possible to the simple method of 1914, in which there was no effective artillery staff at a higher level than the division. War organization will necessarily include some proportion of these higher artillery commands, and peace organization must provide, if not these executive posts themselves, at any rate the means of preparing the officers who may be called upon to hold them.

[1] This was never completed, but a large number of divisions had been so provided by the end of the war.

[2] It must be observed that the American division was much stronger in infantry than a British, French or German, having in fact 12 battalions besides a considerable machine-gun organization.

Ammunition Supply.—Before the war all armies were equipped with mobile ammunition columns, which served the needs both of infantry and machine-guns and of the artillery itself. As a rule certain columns in each formation were supplied with limbered vehicles and field artillery horses, and were as mobile as the batteries, while the remainder, with vehicles of the ordinary army type, possessed the mobility of baggage columns only. In Great Britain a considerable advance toward simplifying the ammunition supply service had been made by introducing lorry transport, worked on the same system as that which provided the army's daily bread, and by attaching a light ammunition column permanently to every brigade of field artillery. But when trench warfare set in, and all supply at the front was based on a system of "dumps," the mobile reserve of ammunition constituted by these brigade ammunition columns was not required. They were therefore put back into the "divisional" ammunition column, or second echelon of supply, which itself was recast on a much smaller scale.[1] In the more open warfare of 1918, however, it was found necessary to return a portion of them to divisional control.

The batteries themselves retained, and necessarily so, all their original wagons.

The organization, and nature of transport, required for reserve ammunition in the future depends principally on the organization and motive power of the batteries. But it may be assumed with some confidence that since mechanical transport improves every year in available numbers, trustworthiness in different conditions, and freedom of movement, horsed ammunition columns are a thing of the past. Even theatres of war for which mechanical transport is unsuitable to-day will be open to it to-morrow.

Organization of Artillery Motors.—During the war the personnel in charge of the artillery motor lorries, tractors, and other motor vehicles were not artillerymen, but were taken from the transport services. This was only a provisional arrangement, due to the fact that the artillerymen were not competent to take charge of motor vehicles. As the motor replaces the artillery horse, this incongruity will naturally disappear, and the artillery will drive their own motors. This will presumably not apply to lorries used to transport guns behind the fighting line, as described above, since these lorries will be general transport, available for other troops when not employed with the artillery. The leading principle is that all men who go into action with the guns, or who are available to replace casualties in the fighting line, must be artillerymen.

Special Artillery and Scientific Auxiliaries.—The introduction of guns of accompaniment, to advance with the front line of the infantry, is contemplated in all armies. The question arises whether these guns are to belong to the infantry, like their own machine-guns, or to the artillery. It is urged on the one hand that the special knowledge required to use a field gun is such as the infantry cannot be expected to attain. On the other hand, infantry officers point out that the gun is not required for general artillery purposes, but merely as a large-bore machine-gun, and that the detachment must be thoroughly familiar with infantry work. The decision between these two views seems to depend on whether the guns of accompaniment are to be used as batteries or as single guns. In the latter case, they should be infantry, not artillery, weapons.

A more difficult question is whether tanks armed with guns are to belong to the artillery or to a separate tank corps. It is easy to draw the line between a fighting tank which has a gun as part of its armament, and a tractor which pulls a gun into action and then waits behind like a limber and team. These are the two extremes, but there are intermediate forms, such as the tank which carries a gun on a platform, capable of fighting either on top of the tank or on the ground, and the tank which is an integral part of the gun-mounting, and is technically an automobile gun-carriage. It seems probable that all these types will belong to the artillery, except the tank proper, in which the gun is only a subsidiary part of the armament.

Finally, it is significant that in reducing the artillery to the minimum imposed by the Peace of Versailles, Germany has chosen to retain both accompanying guns, anti-tank guns and scientific sections (flash-spotting, sound-ranging, meteorological and survey) on the regular establishment of the arm.

(H. A. B.; C. F. A.)

[1] In the new organization, that part of the divisional ammunition column which carried the second reserve of gun ammunition was reduced to one-seventh of its former size.

VI. The Effect of Artillery Projectiles

It is of great importance to the soldier to know the probable effect of artillery projectiles. On the one hand, the artillery commander must know what nature of projectile to use for a given task, and how many will have to be fired, and, on the other, the troops must know what measures to adopt in order to escape the shell-effect, or to minimize it.

The projectiles fired by land artillery are shrapnel shell, H.E. shell, and chemical, incendiary and illuminating shell. They may also have to fire armour-piercing shell at armoured forts and at tanks, though these shell are not part of their usual equipment.

Shrapnel Shell.—This is the most efficient man-killing projectile against troops exposed in the open or when manning a parapet. The French calculate that in 1914, when their artillery fired little but shrapnel, they killed five men of the enemy for every ton of ammunition expended, whereas in 1918, when, after a long period of trench warfare, the proportion was only 5% of field artillery shrapnel to 95% of H. E. shell, they killed only one man per 4 tons of ammunition. The reduction in the proportion of shrapnel carried was due to the difficulty and expense of supply, especially as regards the fuze.

The object of the designer of gun and ammunition, and of the gunner who uses them, is to obtain a dense shower of bullets flying forward close to the ground.

With a view to shrapnel effect, the gun-designer produces a gun with high velocity, long range, and flat trajectory. But a gun equipment of given weight can produce only a given amount of shell energy, which is measured by the product of the weight of the shell and the square of its velocity. Consequently there must be a compromise between a heavy shrapnel and a light high-velocity one. This has been solved differently by different nations, as follows:—

	Weight in Action of Gun cwt.	Weight of Shrapnel lb.	Muzzle Velocity fs.	Number of Bullets to the lb.	Number of Bullets in Shrapnel.
Russia . .	21	14½	1,930	43	260
France . .	23	16	1,740	38	292
Great Britain .	24½	18½	1,615	41	375
Germany .	18½	15	1,525	45	300

The Russian and French guns are best adapted for shrapnel fire. The French use a heavy far-reaching bullet, which, in their flat-trajectory gun, gives a deep zone of shrapnel effect, suited to their bold method of opening fire, which is intended to produce a crushing effect on the enemy with the least possible delay. The Germans were obliged by the low power and curved trajectory of their field gun in which muzzle energy was subordinated to mobility, to abandon the idea of a far-reaching shrapnel and to accept the necessity of expending more rounds for searching a given depth.

Another consideration affecting the question of high velocity versus heavy shell is that the light shell loses its high remaining velocity, which gives the forward impulse to the bullets, much sooner than the heavy shell, so that much of the power of the gun is wasted on overcoming air-resistance, instead of being communicated to the bullets. However, it maintains the initial advantage due to a low angle of elevation up to extreme shrapnel range. The loss of remaining velocity can be partly compensated for by increasing the driving charge in the shell. The shrapnel then acts as a short gun fired close to the enemy. But although this expedient is adopted to some extent in most equipments the limit of efficiency is soon reached, since the large charge reduces the bullet capacity of the shell, and the body has to be made with stout walls, or of very high-grade steel, not always available in war-time, to prevent the shrapnel from blowing to pieces instead of acting as a gun.

Weight of Shrapnel Bullets.—The weight of the shrapnel bullet, which is necessarily spherical, is of great importance to the effect. Elongated shrapnel bullets are out of the question, since there is no means of imparting rotation to them. All attempts in that direction have been failures. Of two spherical bullets the heavier will travel further before pitching into the ground, and so will have a longer period of efficiency. The heaviest metal practically available for shrapnel bullets is hardened lead. Tungsten and other heavy metals have been proposed, but are not available in sufficient quantities for

war requirements. The weight of the shrapnel bullets contained in a shell can therefore be increased only at the expense of their number.

In the other direction, the minimum weight of the bullet is determined by the necessity for providing sufficient disabling energy. It has been found experimentally that a striking energy of 60 foot-pounds is sufficient to disable a man. In the case of a bullet starting from the point of burst with an initial velocity of 1,000 fs., as in the British 18-pr. at 4,000-yd. range, the striking energy after it has travelled 300 yd. is as follows:—

	Weight of Bullet.	Remaining Velocity.	Striking Energy.
France .	38 to the pound	388 fs.	61·5 foot-pounds
Russia .	43 " " "	378 "	52·8 " "
Germany	45 " " "	370 "	47·2 " "

It will be seen that under the assumed conditions the French bullet of 38 to the pound is the only one which provides sufficient striking energy at 300 yd. from the burst. Of the nations which took part in the World War, the French, the Japanese, and the United States (who had the French equipment) were the only ones who used the heavy shrapnel bullet. The other nations (except the Russians) considered that the trajectory of their guns was not flat enough to carry a good proportion of the bullets to a distance of 300 yd., and consequently preferred lighter but more numerous bullets which gave a closer pattern over a shorter distance. It would seem that the Russians, with their powerful gun, would have done better to use a heavier bullet.

Technical Employment of Shrapnel.—A shrapnel should be burst in air so that the axis of the bullet-cone passes through the centre of the target. This is a matter of ranging, and is dealt with elsewhere. Further, the distance of the point of burst from the target should be such as to produce the greatest possible effect. This also is a matter of ranging, but the gunner must first know what is the correct distance which he has to attain. This is determined by theory.

The target surface of a man, measured at right angles to the trajectory of a shrapnel bullet, may be taken as ½ sq. yd. when standing, ⅓ sq. yd. when kneeling, and ¼ sq. yd. when lying or firing over a parapet. The best effect is produced when the density of the cone of bullets is such as to provide one effective bullet for each man. The density depends on the target surface offered by each man; it is immaterial, as regards the best distance of burst, whether the men are in a thin skirmishing line or shoulder to shoulder. If the distribution of bullets throughout the cone were uniform—that is, if the shrapnel gave a perfect "pattern"—then at standing infantry the cross section of the cone should contain one bullet per ½ sq. yard. Taking a shrapnel containing 300 bullets, the cross section of the cone at the target would have to be 150 sq. yards. The apex angle of the cone being about 1 in 4, this would fix the best distance of burst at 55 yd. from the target. But the distribution of bullets in the cone is not uniform. If it be assumed to be haphazard (which is nearer the truth), then, according to the Theory of Probabilities, the probable maximum effect is produced when the cross section contains 1·24 bullets for each man. This gives the best distance of burst for the above shrapnel as about 50 yd. against standing men, 41 yd. against kneeling men, and 35 yd. against men lying or firing over a parapet. With the shrapnel of the British 18-pr., which contains 375 bullets, the best distances are 55, 45 and 38 yd. respectively.

The question of the distance of burst is affected by the error of the fuze. If, for instance, the fuze be such that the shrapnel is liable to burst 60 yd. over or short of the desired point, then if this be fixed at 40 yd. from the target some of the shrapnel will be wasted by bursting on the ground. Similarly, the error of the gun will cause "short" rounds to burst on the ground. In the British and in the French services it has been laid down that the distance of burst for field guns is to be such as to appear from the battery 10 minutes of angle (in French notation 3 "mils," *i.e.* 1/1000 of the range) above the target. This corresponds to a distance of burst of 70 yd., and rather less at longer ranges, and gives about 10% of bursts on graze. This distance has been fixed partly with reference to the error of the fuze (which, under war conditions of manufacture, is considerably greater than in peace time), but principally for simplicity. When good fuzes are available better shooting is to be obtained by adhering to the theoretically correct distances given above. Towards the end of the war the Germans used a number of very accurate mechanical time fuzes, and if these come into general use the service height of 10 minutes above the target will no doubt be reduced.

Penetration.—Even the heavy French shrapnel bullet will not pierce the thinnest of the steel gun-shields in use, and it is quite ineffective against infantry shields, loophole plates, and the plates of a tank. These shields are all made to resist infantry bullets, which have much greater power of penetration than leaden shrapnel bullets.

Steel shrapnel bullets will pierce gun-shields if the shrapnel be burst close up.[1] As the steel bullets are larger than leaden bullets of the same weight, their use entails a reduction of about 20% in the number of bullets in the shrapnel. For the same reason they do not fly so far, and shrapnel filled with them are less effective against infantry. Tungsten steel bullets containing 14% of tungsten would be as heavy for their size as bullets made of the ordinary lead-antimony alloy, but difficulties of expense and supply will probably prevent their introduction.

Percussion Shrapnel.—Shrapnel are invariably fuzed with time-and-percussion fuzes, constructed to burst either in air or on graze. The object of the percussion arrangement is almost entirely to assist ranging by giving visible bursts on the ground. The bullet-effect of shrapnel burst on graze is negligible, as the shell rises steeply from the crater before it opens, and the bullets are blown out in an upward direction, and lose their effective velocity before coming down again. Occasionally the ground may be so hard and the angle of impact so small that the shell ricochets low instead of forming a crater and shower, viz. upwards. But generally speaking percussion fire with shrapnel at troops in the open is a waste of ammunition.

When a direct hit on a gun-shield is made with shrapnel shell the shell does not open till it has travelled several feet further, unless it hits the gun or some solid part of the carriage, and there is no bullet-effect on the detachment. As a rule, a direct hit from a field shrapnel on a modern cellular ammunition box does not blow up the contents, though it may explode a H.E. shell if it makes a fair hit on it, and it may set fire to some of the cartridges.

When percussion shrapnel are fired at a building the shell explodes as it passes through the wall, and produces good bullet-effect on anything behind, as in this case the check is sufficient to give the base burster time to ignite. It used to be held that troops were safe from shrapnel behind two walls, and this is literally correct; but there are so many windows in the front of a house that the shrapnel is liable to pass through them and burst through the back wall, and moreover, under the fire of powerful modern field guns the front wall soon ceases to exist.

Owing to the charge of black powder which it contains shrapnel has considerable incendiary effect on buildings.

Howitzer Shrapnel produces its characteristic effect by the bullets striking downwards at a steep angle 40 degrees or more to the horizontal. The object is to reach troops behind a parapet or gun-shield. The depth of effect, being proportionate to the cosine of the angle of impact, is much less than with a flat-trajectory gun. Precise ranging and an accurate fuze are required to produce good effect. During the first or mobile phase of the war shrapnel fire from field howitzers gave excellent results; later, however, the difficulty of procuring good time fuzes for howitzers brought this class of shell into disrepute, and it seems probable that its use will be discontinued except for light field howitzers, and even in these reserved to mobile warfare.

The theory of the effect of howitzer shrapnel is the same as for gun shrapnel. The weight of the bullet is increased to compensate for the low remaining velocity. The angle of descent of the lowest bullet, including half the angle of opening, is about 40 degrees to the horizontal, so that a man would have to crouch very close behind a gun-shield or parapet to escape being hit. When burst at effective height a field howitzer shrapnel, such as that of the British 4·5-in. howitzer, covers a space 35 yd. wide and 70 yd. from front to rear.

Universal Shell.—These are combined shrapnel and howitzer shell; a type is described and illustrated in 1.869. The idea is that when burst in air at shielded guns the head flies forward and acts on impact as a small H.E. shell, powerful enough to disable the gun if it strikes it, or to reach the men behind the gun-shield with splinters flying sideways or even backwards, while the body of the shell acts as an ordinary time shrapnel. If the whole shell is burst on impact it detonates like a H.E. shell. Such shell were used in the war, but their usefulness was always a matter of controversy and their complicated design made supply difficult.

High-Explosive Shell.—These were the principal projectile fired by all natures of land artillery during the long period of trench warfare in the western theatre of war. They are of two kinds, thick-walled shell and mine shell. The former have a comparatively small burster and are intended to kill men with their splinters; the latter are thin-walled shell containing a large burster, and are intended to penetrate deeply before bursting, and to destroy fortifications and material. Mine shell are fired from howitzers, in which they are exposed only to a low pressure in the bore. In modern howitzers, which are required to range at least 50% further than those in use in 1914, the endeavour is made to keep down the pressure as far as possible by increasing the length of bore, thus getting more work out of the same charge. But the increase of range which can be obtained in this way is hardly sufficient, and heavier charges are inevitable. Mine shells for such pieces have to be made thicker in the walls to prevent them from collapsing in the bore, and tend to approximate to the thick-walled type.

Thick-walled shell are almost always fired with instantaneous percussion fuzes; occasionally they are fired with time fuzes to burst in air. The object of the instantaneous fuze is to burst the shell on the surface of the ground before it has time to penetrate, so that the splinters are not wasted by being smothered in the crater. Thus, early in the war, the German howitzer shell, for want of an efficient instantaneous fuze, used to penetrate deeply into the soft clay of Flanders, and the result was a vertical eruption of mud and splinters which was harmless to men not actually on the spot struck. Instantaneous fuzes are also used to burst H.E. shell in the act of passing

[1] These were actually used to a small extent by the Germans towards the end of the war, possibly on account of shortage of lead.

through a gun-shield, thin wall, thin parapet, etc., so as to produce splinter effect on troops immediately behind it. When an instantaneous fuze acts properly the effect, even on soft ground, is to form a saucer-shaped crater not more than 6 in. deep, in which no splinters are to be found. With flat-trajectory guns the splinters fly forward and sideways, and no reverse effect on troops behind cover can be expected; with howitzers fired so as to give angles of descent of 30 to 45 degrees a few splinters from the base come back, but the reverse effect is slight; with howitzers fired at angles of elevation between 45 and 65 degrees, giving angles of descent of 55 to 75 degrees, the effect is almost equal in all directions.

The size and weight of the splinters are of great importance. Owing to their irregular shape small splinters do not fly very far. The object of the ammunitinn designer is tu get as many effective splinters as possible. As the result of experiments it is cunsidered that the best man-killing weight is 25 grammes (0·88 oz.), though splinters as small as 10 grammes (0·35 oz.) may be effective close to the point of burst. It is nut always possible tu realize this ideal; the French field gun H.E. shell, weighing 11·68 lb., gives only 50 effective splinters, averaging 100 grammes (3·52 oz.). The German 1914 field-gun shell, weighing 15 lb. gave 135 splinters averaging 1·65 ounces. A more recent prujectile, that of the French 7·7-pr. trench gun, gives 90 splinters uf abuut 1·2 ounces. Theoretically it is possible to design a shell so as to pruduce any required fragmentatiun. A violent H.E. burster tears a suft metal shell to minute fragments, while a mild burster in a hard steel shell merely breaks it intu a few large pieces; the designer has to adjust the violence of the burster to the hardness and "shock-test" strength of the steel so as to produce the desired number uf fragments, as uniform in weight as possible. But in practice the problem is a difficult one, as the stresses to which the shell is subjected in the gun, and the shape and balance desirable for ballistics, have to be taken into accnunt. However, manufacturers produce a fair approximatiun; thus Krupp claimed to get 20 splinters of 25 grammes and over per kilugramme of field-gun shell, nr about 9 per pound.

The French field-gun shell is effective over an area of 25 sq. metres only, but with large calibres much better effect is obtained. Roughly, a 6-in. howitzer shell, weighing 100 lbs., clears an area of 300 sq. yards.

During the war considerable success was obtained in firing thick-walled H.E. shell frum flat-trajectory guns with percussion fuzes giving a slight delay actinn, so as to burst in ricochet in the air from 20 tu 30 ft. above the ground. Ricochet fire is applicable only when the angle of impact is so small, and the gruund so hard, that the shell has no tendency to bury itself. With an angle of opening of about 120 degrees the downward and lateral effect is good, and the furward effect is appreciable, though far inferior to that of time shrapnel. This method was evolved by the French before the war; the ricochet effect is styled the "*coup de hache.*" It was used also for wire-cutting.

Mine Shell.—With huwitzers above 6 in., mine shell, not man-killing shell, are usually employed. With medium and heavy guns mine shell are not used except at lung ranges, where the angle of descent is steep enough to ensure deep penetratiun, and even so, for the reason abuve given, they have tu have fairly thick walls and lose correspundingly in explosive capacity. Heavy high-velocity guns therefore usually fire nnly shell of the thick-walled type, bursting on graze and producing effect by the action of heavy splinters. There is nuw, however, a tendency to employ reduced as well as full charges with guns, in nrder to save wear, and with these it will be possible to use efficient mine shell.

The burster nf a mine shell is of such a nature as to do as much work as possible in displacing earth. A very violent explosive of the fulminate type, even if it could be used, would be less effective than T.N.T. or amatol (*see* AMMUNITION) because its action is too local, and much of the force of the explusion wnuld be wasted on pulverizing the earth at the point of explosiun instead uf shifting it. The fuze has tu be made with a delay suitable to the ballistics and to the nature of the ground; if the shell penetrates too deeply it forms a "glube uf compression" or hollnw chamber beneath the surface, while if it does not penetrate deeply enuugh much of the energy is wasted on the air. The mine shell of the German 15-cm. (5·9-in.) howitzer was effective; it penetrated to a depth uf 3 to 4 metres, at which depth its burster of 18 lb. of picric acid gave good mine effect.

Effect on Tanks.—Fire from all natures of guns and howitzers is effective on unarmoured or lightly armoured tanks. The best projectile is H.E. with normal or instantaneuus fuze, as the delay action fuze is liable to cause the shell to pass right through and out again before it bursts. In one instance during the war a German tank protected by 30-mm. (1·18-in.) hard steel armour was fired on by British 18-prs. firing ordinary thick-walled H.E. shell at ranges of 3,000 to 4,000 yards. It was disabled, and on examination it was found that several of the shell which had struck it had just failed to penetrate. The effect obtainable with armour-piercing shell is described below.

Effect on Armoured Forts.—The penetration of armour is discussed under *Armour-Piercing Shell.* But this is not the only means of reducing an armoured fort. The Germans obtained effect on the Belgian forts in 1914 chiefly by "undermining" fire. The mine shell of their superheavy howitzers, with delay-action fuzes, buried themselves almost under the foundations of the cupolas, and either blew the latter up and out of their seatings, or racked the whole concrete mass so severely that the machinery was put out of action. Or, again, they ruined and blocked up the vaulted passages and so prevented access to the cupola chambers.

In future constructions it has been proposed to guard against this method of undermining by extending and strengthening the apron surrounding the cupola. The ground for 50 metres round it is to be protected by one or more layers of blocks of hard cast-iron, one metre cube, each weighing 8 tons. These are to be sandwiched between layers of concrete, and are expected to burst all shell on the surface. This method, if applied, will probably be effective against undermining. There remains the possibility of damaging the projecting muzzles of the guns with heavy splinters from thick-walled shells, and of penetrating the armour with armour-piercing shell from high-velocity guns. An attack with gas is also possible.

Effect on Field Entrenchments.—Gun emplacements and dugouts require a "bursting course" of rails or stones at or near the surface of the earthen roof, otherwise the emplacements are easily penetrated. Even a field-howitzer shell with delay actiun will gu thruugh 5 ft. of earth and blow in a timber ruuf beneath it. Duuble roofs of rails with an air-space of 8 to 12 in. between them are used when possible, and such a ruuf, with 5 ft. of earth and a bursting cuurse on top of it, is fairly safe against a single hit from a 6-in. huwitzer shell. For protectiun against 8-in. and heavier natures it is necessary to burrow 20 to 30 ft. underground.

Concussion and Asphyxiation Effects of H.E.—A mine shell uf 6-in. calibre and upwards does great damage when burst inside a building, dugout, or other confined space, by the force uf its blast, irrespective of splinter effect. The same effect, to a lesser extent, is pruduced by thick-walled shell. Walls of buildings are blown out, and men in the ruom in which the burst takes place are killed by the concussion. The idea that puisonous gases are produced by the detonation of high explosives is a mistake; only small quantities of carbunic acid gas and carbonic oxide are generated, and these, except in a deep dugout, are quickly dissipated by the inrush of air which succeeds the blast. However, it was found at Liége and Antwerp that the deeply sunk ammunition runms below the armoured forts were rendered uninhabitable by the fumes frum mine shell filled with picric acid which penetrated them or burst undergruund near them. These were presumably acrid fumes due to the incumplete detonation of the bursting charges.

High-Explosive Shell with Time Fuzes.—These were uriginally introduced for the German field gun, in order to attack troops in deep trenches. The method used was to burst the shell exactly over the trench, and to obtain effect by splinters striking downwards. But even under peace conditions of precision of fire it was found that an average of four shells were required to hit one man, and under war cunditions the expenditure of ammunition was out of all proportion to the effect pruduced. In the war, the Germans occasionally used time H.E. shell for annoyance, on account of their supposed moral effect on troops in trenches. Their use ceased altogether when time and percussion fuzes fur H.E. shell were withdrawn. A H.E. shell has little or nn incendiary effect.

Smoke Shell.—These are used to form a screen between our troops and the enemy. In barrage fire time shrapnel produce quite enough smoke to make an opaque screen; but when a barrage is formed with H.E. shell, these are mixed with 25 % of smoke shell to make a good screen. This method was frequently used by the French, either because of shortage of field shrapnel, or because the barrage was carried beyond shrapnel range.

Incendiary Shell.—During the retreat the Germans used these shell to set fire to villages which they had evacuated. Some were of the ancient "carcass" type, filled with black powder and grease, and spuuting flame from holes in the walls; others were filled with petroleum. The British introduced *thermit shell*, filled with aluminium dust and irun oxide, which, when ignited, form molten iron. The filling consisted of short cylinders of thermit, like firework stars, and the shell was preferably burst in air like a shrapnel, so as to blow the stars out forwards. These were used to a small extent in the Allied advance towards the end of the war, and gave good results.

Illuminating Shell.—These contain firework stars, which are ignited by a time fuze at such a height as to give them time to burn out before reaching the ground. They are fired principally from field howitzers.

Armour-Piercing Shell.—These may have to be used against armoured tanks, and turrets and cupolas of land defences.

The effect of field gun armour-piercing shell against tanks depends not only on the thickness of the armour but on the manner in which it is supported, and the angle at which it is struck. The following table of penetration for the British 18-pr. gun used in the war may be taken as a guide. It is assumed in the table that the armour is efficiently supported and that it is struck at an angle not exceeding 30 degrees to the normal. The formula is:—

$$t = \frac{vd}{2500 - \cdot 4v}$$

where t is the thickness of hard-faced armour in inches, v is the striking velocity in f.s., and d is the calibre of the gun in inches.

Penetration of Tank Armour by 18-pr.

Range yards.	Thickness of Armour Penetrated inches.	Weight of 10 square yards[1] of Armour tons.
1,000	2·331	3·902
2,000	1·914	3·204
3,000	1·633	2·798
4,000	1·520	2·544
5,000	1·409	2·360
6,000	1·323	2·215

The effect of armour-piercing shell, fired from high-velocity guns, in penetrating armoured turrets and cupolas, is given by the same formula. As an example, a 30·5-cm. (12-in.) gun may be expected to pierce the following thickness of hard-faced armour:—

Range, yards . .	5,000	10,000	15,000	20,000	25,000
Penetration, inches	12·5	9·25	7·5	7·25	7

At 6,000 metres the 240-mm. gun penetrates 180 mm., and the 155-mm. G.P.F. gun penetrates 77 mm.

The cupola must be massive as well as stout, or else the effect of the blow will be to displace it and jam the rotating machinery, even if the shell does not penetrate. In the Liége and Antwerp cupolas, which were intended to resist 6-in. guns, lead cushions were used to reduce the "racking" effect. A small cupola of three metres in diameter cannot be expected to stand blows from heavy shell, though it may be stout enough to resist penetration. The striking energy of a 12-in. shell at 5,000 yd. is about 20,000 foot-tons.

At the beginning of the war, a fort was at a disadvantage in that its position was known, whereas it was fired on by long-range guns which could not be located, unless the aircraft of the defence retained the mastery of the air. The development of sound-ranging helps the defence in this respect, provided that the instruments can be set up in several forts connected by telephone.

VII. Effects of Collective Artillery Fire

These vary so much according to local and tactical considerations that no exact rules can be laid down. However, the following were rough working rules established during the war:—

Standing Barrage.—To keep down the fire of riflemen in a trench, each man should be liable to be killed if he shows himself above the parapet at least once a minute; therefore one shrapnel per minute should be burst in front of him. Taking the effective spread of shrapnel bullets at 25 yd., then 4 rounds per 100 yd. of trench are required. This is an "ordinary" barrage, and may be changed to a "heavy" barrage of 8 rounds a minute or a "light" barrage of 2 rounds a minute per 100 yd. as required. If a 4-gun battery has to barrage a trench of 300-yd. front, then at the "ordinary" rate each gun will fire 3 rounds a minute, distributed over the 75 yd. allotted to it. To barrage a communication trench "end on," 2 rounds a minute per 100 yd. of length are sufficient, when the line has been corrected to bring every burst over the trench. It is not necessary to barrage the whole length of a communication trench, which may be 2 m. long; aeroplane photographs show the most effective barrage points, namely the "defiles" at which there is no way round. Communication trenches may be so effectively barraged as to oblige the enemy to risk the chance of coming and going across the open.

Creeping Barrage.—This may be of several different kinds, as described above. With time shrapnel, or a mixture of H. E. and smoke shell, fired from field guns, a battery can efficiently barrage a front equal to its own normal front, or 20 yd. per gun. (The French reckon 15 metres per gun.)

In the British service the normal barrage rate was 4 rounds per field gun per minute for 2 minutes, then "lift" to the next range and repeat, and so on. On emergency a battery can cover a wider front for short periods; the comparatively slow rate of fire is due to the constant changes in elevation and setting of fuze, and possibly in direction as well. However, this rate amounts to 240 rounds an hour per gun, which is about as much as a battery can do.

The French reckoned 2 rounds per 15 metres of front per minute for a "heavy" barrage, down to the same per 45 metres of front for a "light" barrage. The Germans, in 1918, advanced their barrage by "bounds" of 200 metres for field guns and 400 for medium guns and howitzers; after each bound the guns continued to fire at the same range ("pounding") for some minutes. Owing possibly to worn guns, the German barrage was considered less dense and less effective than that of the Allies, although the nominal rate of fire was higher.

When firing a barrage with time shrapnel, the bursts must be kept low, and a setting of fuze giving 50 % of bursts on graze is considered the best. With H.E. shell instantaneous fuzes are best, unless there are no smoke shell in the barrage; in this case it may be better to use normal fuzes, in order to throw up more dirt and make a more opaque screen.

Bombardment.—It is found that a field H.E. shell displaces 4 cub. metres of earth per kg. of burster, or $2\frac{1}{2}$ cub. yd. per pound. With larger calibres the effect increases in a somewhat higher ratio But the number of rounds required for a given task cannot be ascertained directly from these premises, since much of the effect of subsequent shell falling in or near the same place as the first shell is wasted by displacing the earth already lifted, which has fallen back into the crater. A more reliable guide is the diameter of the crater, which varies according to the soil. In ordinary ground a 6-in. howitzer mine shell, containing some 13 lbs. of H.E. makes a cylindrical crater about 4 yd. wide and 3 yd. deep, of which depth about one-third is filled up by earth falling back into it. Hence to destroy a 12-ft. parapet it must be struck by one 6-in. shell per 4 yd. of front. If a calibre be employed which gives a crater of less diameter than the thickness of the parapet, this will entail a great waste of ammunition. Thus the French found that under practice conditions of accuracy it took 11 rounds of field-gun shell per yard to breach a parapet 10 ft. thick, or perhaps 20 rounds a yard under war conditions. Therefore they consider that for practical purposes a 10-ft. parapet is proof against field guns and 4·2-in. field howitzers.

[1] A tank armoured in front only may require some 10 sq. yd. of armour.

At stout brick and concrete walls, H.E. shell with "normal" fuzes (*i. e.* neither instantaneous nor delay action) are very effective. A wall 20 in. thick is cut down by an expenditure of two or three field gun shell per yard. A field-gun shrapnel will pierce a wall of this thickness at medium range.

At field guns in the open, the French reckon 15 rounds of field-gun shell at 3,000 metres, or 25 rounds at 3,500 metres, to make a hit on a gun. The British 18-pr., under experimental conditions, is capable of making 60 % of hits on a gun in action at 2,000 yd., 16 % at 3,000 yd., and 5 % at 4,000 yards. Medium guns such as the 60-pr. or French 4·2-in. maintain their accuracy to longer ranges than field guns; a rough rule is to add one-third to the field-gun range for the same percentage of hits; thus a 60-pr. is capable of making 16 % of hits on a gun at 4,000 yards.

The following experimental results (Krupp) show the comparative effects of various natures of field-gun and field-howitzer shell fired at a battery of four guns in action, a wagon beside each gun:—

(*a*) H.E. field-gun shell, percussion fuze. Range 5,000 metres. One hundred rounds disabled 1 gun, 1 wagon, and 11 dummy men out of 34.

(*b*) The same, time fuze. One wagon damaged, 4 dummies put out of action.

(*c*) The same target, range 2,000 metres, fired at with 4·2-in. howitzer (presumably similar to the German service field howitzer). Time shrapnel. Twenty-four rounds fired after ranging had been completed with 11 rounds percussion. Result, 26 dummies put out of action out of 34.

A heavy discount must be taken off these experimental results for war conditions, especially in view of the quality of war-time fuzes. However, the general inference is that percussion H.E. shell is a much better projectile to fire at a battery in the open than time H.E. shell, and that field-howitzer time shrapnel is remarkably effective when the range and fuze can be correctly found, though it probably takes much longer to produce effect with it than with H.E. shell. In duels between field batteries, such as often unexpectedly occurred during the war, it is all-important to knock out the enemy's guns as quickly as possible, and percussion H.E. shell with instantaneous fuze is the best projectile to use.

Wire Cutting.—The development, during the war, of the methods of cutting barbed wire by the fire of artillery has already been described. With the British 18-pr. at ranges of 600 to 1,800 yd., a belt of ordinary barbed wire entanglement 8 yd. deep can be cut through with an expenditure of about 10 yd. of time shrapnel per yard of front. The process is slow, as very precise shooting is required. A better projectile is 4·5-in. howitzer H.E. shell with instantaneous fuze; each effective round, at ranges up to 6,000 yd., clears a circle about 3 yd. in diameter. Howitzer H.E. shell with normal or delay-action fuze makes a crater into which the network of wire falls back, and so makes a worse obstacle than before. A 52-lb. trench mortar bomb with instantaneous fuze clears a circle 5 yd. in diameter. The French in 1918 used field guns firing H.E. shell, either with instantaneous fuzes or with a slight delay action to burst the shell on ricochet. The lines of fire were 5 metres apart at the target. At a belt of strong wire 25 metres deep it was found that 600 rounds were required to clear a lane 25 metres wide. The ranges were from 2,000 to 4,000 metres. Tanks, when available, are much better wire-destroyers than artillery.

Fire with Star Shell.—These are used for illumination, and are usually fired from field howitzers. They must be burst at such a height that the stars burn out before reaching the ground; otherwise they form a smoke screen on the ground, besides setting fire to dry vegetation. A star shell, properly burst, lights up a circle about 50 yd. in diameter effectively, and patrols are distinguishable up to about 100 yards. For continuous illumination, four shell per minute per 100 yd. of front gives good results. (See also, generally, the article Ordnance.) (H. A. B.)

ARTOIS, BATTLES IN (1914–7), *see* Plates I., II., III. and IV.—(*A*) First Battle of Arras (Sept. 30–Oct. 8 1914).—After the stabilization of the battle-front on the Aisne and to the E. of it, about Sept. 16, both the Allied and the German Higher Commands

ARTOIS, BATTLES IN (CAMBRAI-LE CATEAU, 1914)

PLATE I.

proceeded to despatch forces to their northern flanks, with the object of outflanking the hostile battle line. There thus ensued what is known as "the Race to the Sea," which ended about the middle of Oct. in the establishment of a continuous front from the Belgian coast to Switzerland. On this front, after a series of furious battles which raged until well into Nov., both sides settled down to trench warfare on the advent of winter.

The first attempt to outflank the German right N. of the Oise was entrusted to the French Second Army, under Gen. de Castelnau, which was transferred from Lorraine from Sept. 10 onwards. This army, consisting of the XIII., IV., XIV., XX., and XI. Corps, was eventually opposed by the German IX. Reserve, II., XVIII., XXI., I. Bav., II. Bav. and XIV. Reserve Corps, brought up from various parts of the line, and after heavy fighting, in which first one side and then the other held temporary and local advantages which proved impossible of exploitation, these forces were left facing each other on the general line Lassigny-Roye-Chaulnes-Albert-Hebuterne, on which they finally fortified themselves. The battle on the front of the French Second Army died down in this fashion about the middle of October. Before this date the further prosecution of the mutual attempt at envelopment by both sides had brought about an extension of the fighting to the neighbourhood of Arras and Lens.

Battle of the Tenth French Army around Arras, Sept. 29–Oct. 10.—The front of the Second Army was prolonged to the N. by the group of Territorial Divisions (the 81st, 82nd, 84th and 88th) under Brugère, which had been ordered on Sept. 29 to push forward detachments to cover the detrainment of reinforcements at Arras and Lens, and by the 1st Cavalry Corps (Conneau) (1st, 3rd, 5th and 10th Cavalry Divisions) which was holding the line of the Cojeul on the left of the territorials. On Sept. 30 Gen. de Maud'huy was given command of a "Detachment of the Second Army," consisting of the X. Corps, two divisions (the 70th and 77th) formed into a Provisional Corps under D'Urbal, and the 1st Cavalry Corps; his orders were to concentrate in the region of Arras and to act against the right flank of the German corps facing the Second Army. It was believed that this flank would be found about Bapaume. Of the forces at Maud'huy's disposal the X. Corps was on this date marching from Amiens in the direction of Arras, being still some two days' march from the latter place, while the divisions of the Provisional Corps were commencing to detrain at Arras, covered by the 1st Cavalry Corps in the line of the Cojeul and a mixed Territorial detachment at Douai.

The situation of the enemy on the front of the detachment, somewhat obscure on Sept. 30, became clearer on the following days. Strong hostile forces (the IV. German Corps) were reported as moving N. and halting for the night in the neighbourhood of Quéant, with the evident intention of falling on the flank of the Second Army, at this time around Courcelles. The advanced guards of these columns had got into contact with the French cavalry on the line of the Sensée. Further to the N. other German troops (the I. Bavarian Reserve Corps) had driven the advanced troops of the Territorial detachment back to Douai.

Despite the fact that the battle showed as yet no signs of dying on the Second Army front, that the enemy were pressing hard against his centre, and that a shortage of munitions was beginning to make itself felt, Gen. de Castelnau adhered to his original intention of enveloping the hostile left with the detachment under Maud'huy on Oct. 2, and orders to this effect were sent to the latter on that evening; Maud'huy had already made his preparatory dispositions. The X. Corps was to be assembled around Ficheux, the divisions of the provisional corps N. of Neuville Vitasse and at Gavrelle, the Cavalry Corps N. of Monchy-le-Preux; all were to be in position by 6 A.M. The X. Corps and the 77th Division and the main body of the cavalry were to be ready to advance south-eastwards next morning against the flank of the enemy around Quéant, while the 70th Div. at Gavrelle was in a position either to coöperate in this advance or to deal with any hostile forces advancing by Douai. In continuance of these instructions, the X. Corps was [illegible] early next morning to move eastwards to Mercatel, where it was to advance against the line Ervillers-St. Leger, and then in the general direction of Mory, as soon as orders were received from Gen. Maud'huy.

Before, however, the X. Corps had reached its area of concentration around Mercatel the 77th Div. on its left was assailed from the E. by newly arrived German troops (the IV. Corps), who forced it back from the Cojeul to the line Guemappe-Monchy-le-Preux, while at the same time the I. Bavarian Reserve Corps, which had entered Douai on the evening of the 1st, was pushing its advance westwards to the north of the Scarpe—an advance which the 70th Div., delayed in its march from Lens, where it had detrained, to Gavrelle, was not yet available to oppose; the X. Corps was therefore ordered to change the direction of its proposed advance from S.E. to N.E., and assigned as its new line of attack the course of the Cojeul and as its objective the crest N. of Croisilles and W. of Heninel. The Corps would thus strike in flank the enemy advancing S. of the Scarpe, who by 2 P.M. had taken Monchy-le-Preux and driven back the 77th Div. to the line Neuville Vitasse-Feuchy Chapel. Meanwhile the 70th Div. on the N. bank of the Scarpe, advancing towards Gavrelle, had been held up and thrown on the defensive on the front Rouvroy-Izel-Bailleul, so that between it and the 70th Div. to the S. there existed a wide gap, which the 1st Cavalry Corps was urgently ordered to fill to the best of its ability.

Owing to the change of direction which had been ordered the attack of the X. Corps was not delivered till the late afternoon, and made little headway against the IV. German Corps, so that at the end of the day a further gap in the French line was formed between the left of the X. Corps and the right of the 77th Div., which had to be filled by troops from the general reserve. Gen. de Maud'huy, despite the disappointment of the day, ordered that the X. Corps should be prepared to resume its attack next morning, the 3rd on the N. bank of the Cojeul in the direction of Monchy-le-Preux, while the remainder of the detachment was to maintain its positions of the previous day. The X. Corps, however, met with no better fortune on this day; the Germans maintained themselves in Neuville Vitasse after heavy to-and-fro fighting, and the retirement of the Territorial troops to the S., who were forced out of Courcelles by the attacks of the German Guard Corps, compelled the X. Corps to throw back its right in conformity, under severe enemy pressure, as far as the line Ficheux-Mercatel. Both the 77th and 70th Divs., however, succeeded in repelling all the violent efforts of the enemy; the gap between these two divisions in the Scarpe valley was successfully closed by Conneau's 1st Cavalry Corps; and reinforcements consisting of the XXI. Corps (Maistre), detraining at Armentières, Merville and St. Pol, and the 2nd Cavalry Corps (4th and 5th Cavalry Div.) under De Mitry, then holding the front Benifontaine-Lens, were placed at the disposal of De Maud'huy. These forces were increased by the 45th Div. detraining at Arras, which was assigned to D'Urbal's corps.

On the front of this corps fighting continued throughout the night, and the 70th Div. was forced to withdraw some three miles westwards to the line Vimy-Farbus-Bailleul, along the eastern slopes of the Vimy ridge. This retirement uncovered Lens, which fell into German hands early on the 4th. The situation of the detachment, which now found both its flanks in the air, was by no means an easy one; Maud'huy's orders for the 4th, however, were that the positions then occupied were to be held at all costs. The X. Corps was to maintain itself on the line Tilloy-Beaurains-Mercatel, with its right flank thrown back if necessary to Ficheux, and to reëstablish the connexion with the left of the Second Army which had been lost owing to the retreat of the Territorials. D'Urbal's corps was to hold its ground on the front Vimy-Bailleul-Athies-Feuchy Chapel, so as to allow time for the XXI. Corps to advance by La Bassée against the flank of the I. Bavarian Reserve Corps, which was attacking N. of the Scarpe. The 1st Cavalry Corps was to

secure the left of D'Urbal around Givenchy-en-Gohelle. One brigade of the 45th Div. which had already been despatched to Arras was sent forward to reinforce the Provisional Corps, and the second was detrained at Beaumetz and passed on to Duisans in general reserve.

. The German attacks continued without cessation throughout the 5th.

Prince Rupprecht of Bavaria, commanding the Sixth German Army, arrived at Douai and took command of the whole battle front between the Somme and the Lys. On the French side Gen. Foch was entrusted with the coördination of the front N. of the Oise, and with the general control of the Second Army, the Territorial group, the 1st and 2nd Cavalry Corps and Maud'huy's command, which now became the Tenth Army; Foch moved his headquarters to Doullens on the 5th, Maud'huy's remaining at Aubigny.

During the greater part of the day the Tenth Army successfully held its ground, but in the evening its left was forced to retire still further W. by the vigorous attacks of the I. Bavarian Reserve Corps, to the N. of which the 2nd German Cavalry Corps of von der Marwitz was now coming into action. Givenchy fell into the hands of the Bavarians, and while their right advanced beyond it to Souchez their centre assaulted and carried the Vimy ridge as far S. as Thelus; the French cavalry were driven back to Villers au Bois and Mont St. Eloi, while the 70th Div., reinforced by all available troops of the 45th Div., again made head against the enemy on the line Carency-Neuville St. Vaast-Roclincourt-Athies. This was the situation reported to Gen. Maud'huy on the morning of the 5th; and shortly after this bad news had been received the X. Corps announced that its right had been forced back from Boisleux, where it had maintained itself throughout the previous day, to Ficheux; that hostile columns were reported moving round its flank by Blaireville; and that the stations of Beaumetz and Saulty on the Arras-Doullens railway were being bombarded.

This was about 10 A.M., and in view of the extreme gravity of the situation on both his flanks Gen. Maud'huy was already taking preparatory measures for the evacuation of Arras and for a withdrawal in the direction of St. Pol, should such become necessary as a result of further progress by the enemy, when Gen. Foch arrived at his headquarters and it was decided to make another effort to restore the position. The Germans had not pressed their advantage against the left of the army to the extent that had at first been feared; the Cavalry Corps was therefore ordered to advance against the right, which had pushed no further forward than Souchez, and disengage the left of the 77th Division. D'Urbal's corps, which was about to fall back to the line Mont St. Eloi-Etrun-Warlus (W. of Arras), was directed to maintain its ground with its right and centre and coöperate with its left in the attack by the cavalry. Meanwhile reconnaissances had revealed the fact that neither the German IV. Corps nor the Guard had yet taken advantage of the gap between the X. Corps on the right of the Tenth Army and the Territorials on the left of the Second Army; the former was therefore instructed to maintain its line and echelon troops in rear of its right between Ficheux and Gouy. Accordingly on the evening of the 5th the X. Corps had established itself firmly on the front Beaurains-Rivière. The attacks of the Cavalry Corps and the 70th Div., however, made no headway, and their line was established at the end of the day at the western foot of the Vimy ridge on the front E. of Mont St. Eloi-S. of Neuville St. Vaast-Ecurye-Roclincourt-St. Laurent. Further S. the line was continued by the 77th Div., which had been drawn back in conformity with the retirement of the formations on both its flanks to the second position prepared in rear, between Blangy and Tilloy.

The orders for the 76th were for a renewal of the attack on the left wing of the Tenth Army; it was to be carried out by the 43rd Div. (of the XXI. Corps) which was assembling W. of Carency, the 1st and 2nd Cavalry Corps which were to advance between Souchez and Liévin, and the XXI. Corps (less the 43rd Division) which was to envelop the enemy's right advancing by La Bassée and Lens on Vimy. Various untoward circumstances combined to thwart the execution of this plan. The attack of the Cavalry Corps began late and with insufficient forces, could make little impression on the strong front held by the enemy between Notre Dame de Lorette and Angres, and the 43rd Div. to the S. of it was also held up, while the enveloping attack of the XXI. Corps from La Bassée failed to develop. Elsewhere on the front the German attacks were repulsed, and by the evening the army held the line Beaumetz-Arras (X. Corps), Arras-W. of Neuville St. Vaast (Provisional Corps)-Carency-Aix-Noulette (43rd Div. and Cavalry Corps)-S.E. of Grenay-Loos (XXI. Corps) with cavalry towards Pont à Vendin and Carvin. Arras was being shelled by the enemy.

According to army orders the XXI. Corps commenced its attack early on the 7th against the enemy reported to be on the line Angres-Liévin-Lens, while the cavalry and the 43rd Div. continued their endeavours to press forward towards Notre Dame de Lorette and Souchez. The Germans, however, had strengthened their positions during the night, and little progress could be made. Moreover, it had become evident that the battle line must be extended yet further to the N. in order to meet a renewed German attempt to envelop the French left by the valley of the Lys. Accordingly the 1st and 2nd Cavalry Corps were withdrawn from the battle-front in the late afternoon preparatory to their despatch to the N., the 13th Div., then in the vicinity of Lille, being ordered S. to take their place in the Tenth Army. On the rest of that army's front the situation underwent no important change during the 7th.

From this date forward the fighting at Arras died gradually away. Renewed efforts by the XXI. Corps on the 8th and 9th ended in the recovery of Notre Dame de Lorette. On Oct. 20 further fighting E. of Arras resulted in an advance by the 10th Corps, and on the 22nd the 77th Div. was forced back N.E. of Arras by strong enemy forces, who were compelled next day to relinquish part of their gains.

These were but the dying flickers of the fire of battle which had long since shifted its main focus to the north.

Extension of the Battle to the Lys Valley, Oct. 3-12.—While the battle of Arras was still at its crisis, the German right wing was already being extended further to the N. into Flanders. On Oct. 3 a mixed detachment of Landwehr entered Tournai; the 4th Cavalry Corps (3rd, 6th and Bavarian Cavalry Divs.) had come into line on the right of the 1st Cavalry Corps, which was then engaged with the French 2nd Cavalry Corps, with its right S. of La Bassée. The right of these fresh forces advanced on Lille, from Tournai and Orchies, while its left advanced from Douai on La Bassée; by the 4th contact had been made with the French in the western outskirts of Lille.

To meet this new threat the French Higher Command had moved up the 2nd Cavalry Corps (4th, 5th and 6th Cavalry Divs.) under De Mitry to the area between Lens and Lille, and had garrisoned the latter city with the 13th Div. (of the XXI. Corps) which had detrained at Armentières, covered by the 7th Cavalry Division. The first attacks of the German cavalry on the city were beaten off and the suburbs cleared; but, as has already been related, the 13th Div. was then called away to the S. to rejoin its corps, and left behind it only a weak detachment of six battalions and four squadrons to hold the city, and of these two further battalions were withdrawn on the 8th. Meanwhile to the S. between Lens and the Béthune-La Bassée canal the XIV. German Corps had come into line, forcing back the French cavalry to the W. of the Lens-La Bassée road to the line Vermelles-Cambrin; on this line heavy and continuous fighting took place from Oct. 10 onwards, where the position gradually became stable.

Further to the N. the German cavalry continued their advance, extending their right as far as and beyond the Lys and covering the whole country from La Bassée by Lille, Tourcoing and Wervicq to Ypres. The centre and left of De Mitry's cavalry fell back before them, pivoting back on their right from Neuve Chapelle by Estaires and Merville to Hazebrouck and Cassel; this line was reached about Oct. 9. The main body of the German

cavalry appeared to be assembled around Bailleul and Steenvoorde, while behind it strong forces of infantry were advancing, the XIII. Corps to the S. and the XIX. to the N. of Lille. The garrison of the city, although reinforced on the 10th by a detachment, were unable to make head against these overwhelming forces, more especially as the presence of the German cavalry in all the area to the W. deprived it of all hope of succour; and after two days' bombardment Lille surrendered to the enemy with its garrison on Oct. 12.

The battle, however, was now about to enter on a new phase with the entry into action of the British army.

Operations of the British in the Lys Valley, Oct. 10–18.—The transfer of the British from the Aisne to the left flank of the French army in Flanders had first been proposed by Sir John French on Sept. 29; the details were quickly arranged between him and Joffre, and the withdrawal from the line commenced on Oct. 1. The cavalry moved off first by road on the 2nd, and were followed by the infantry between the 8th and 12th. Sir John French, on his arrival at Abbeville on the 8th, had planned a general advance by the II. Corps, then detraining there, to the line Aire-Béthune, covered in front and to the left by the Cavalry Corps, and the detraining of the III. Corps to the N. at St. Omer. The IV. Corps and the 3rd Cavalry Div., under Gen. Rawlinson, which had been landed on the Belgian coast in order to assist the Belgians in the defence of Antwerp and had assisted in covering their retirement to the line of the Yser, had been holding the line of the Lys around Ghent on the 11th, and were instructed to maintain themselves between that town and Courtrai for four or five days, if possible; it was intended to bring the rest of the army up on the right of the IV. Corps, so as to hold the Lys line from Ghent southwards. Rawlinson was authorized, however, in case he was attacked by strong hostile forces, to fall back in the direction of St. Omer, and as a matter of fact the retreat of the Belgians to the N. of him eventually necessitated his retirement by way of Thielt and Thourout to Roulers, where the IV. Corps arrived on Oct. 12, unmolested by the enemy.

On the 10th French visited Foch, and a plan for a combined Allied offensive for the 13th, to reach the line of the Lys from Lille-Courtrai, was then drawn up. The British were to advance with their right N. of Lille, to force the river Lys at Courtrai and join up with Rawlinson's IV. Corps below that town. The Belgians were also to coöperate in the north. In accordance with this plan, the British cavalry pushing forward on the 11th came into contact with the German IV. Cavalry Corps, operating before the right wing of the VI. Army, in the neighbourhood of Nieppe forest, and forced them back towards the Lys; the II. British Corps reached the line of the Aire-Béthune canal. By the 14th the cavalry had cleared the country to the E. as far as the Wytschaete-Messines ridge and pushed patrols forward to the crossings of the Lys; but the II. Corps, wheeling up its left in the direction of Merville, became heavily engaged with German infantry (the XIII. and XIX. Corps of the VI. Army), which prevented their making much headway. The III. British Corps, having completed its movement to Hazebrouck by the 13th, began its advance eastwards, to bring it level with the left of the II. Corps. This objective, however, was not attained without serious and sustained fighting; the Germans (XIX. Corps and IV. Cavalry Corps) stubbornly defended Bailleul, Meteren, Neuve Église, Sailly and Nieppe one after the other; by the 16th, however, the British were in possession of all these places. The II. Corps also had worked their way forward by dint of determined efforts to the line Aubers-Givenchy, and came into touch with the XXI. Corps on the left of the French X. Army, on the Béthune-La Bassée canal.

While the II. Corps, despite determined and unceasing attacks, found further progress impossible beyond the line Givenchy-Festubert-N. of Aubers, which it reached on Oct. 18, the III. Corps entered Bois Grenier and Armentières, and was able to establish itself on a line E. of these places, while the Cavalry Corps, guarding their left, continued the line along the Lys to Menin. By the morrow the assembly of the British army in the N. was completed by the arrival of the I. Corps at Po[illegible] St. Omer and Cassel. The battle of the Lys now became m[illegible] in the greater battle of Ypres, in which the whole British fo[illegible] was engaged from Oct. 20 to Nov. 20, and the description of th[illegible] fighting between these dates on the front of the British II. and III. Corps will be found under that head. It may be said, however, that neither the British nor the Germans, despite their utmost efforts, succeeded in bringing about any material change in the situation on the front between the Béthune-La Bassée canal about Givenchy and the Lys to the N. of Armentières.

(*B*) French Offensives in Artois, 1915.—During the month of Oct. 1914 the western front had stabilized across Picardy and Artois, from the Oise to the neighbourhood of La Bassée. The line had not been chosen at the will of either party, but marked the points which each side had reached and held during the confused and rapid series of actions known as the "Race to the Sea." While there was still open country to the north it had been worth no one's while to attempt to dislodge an enemy present in any force. And when the sea had been reached and the German attacks upon the Yser repulsed, neither side retained the energy to advance. Both, therefore, had time to elaborate their defences in comparative peace, and thereby the sinuous and haphazard line already established became permanent.

About Arras the line bulged eastward, leaving Beaurains German but making St. Laurent-Blangy, Roclincourt, and Ecurie French. To the north was a westward bulge which gave the Germans Neuville-St. Vaast and La Targette, Carency and Ablain, Angres, Liévin, and La Fosse Calonne. North of Fosse Calonne the line ran straighter to the west of Loos, Hulluch, Haisnes, and La Bassée.

Artois is a chalk country. The surface soil is clay, with patches of sand unsuitable for cultivation and therefore wooded. The principal natural feature of the region is a long isolated ridge running from N.W. to S.E., which overlooks all the countryside. This ridge culminates at the chapel of Notre Dame de Lorette. East of the chapel there is a gap marked by the village of Souchez. East of Souchez again, the ridge continues as Vimy ridge and gradually dies away south of Vimy village.

The sector was of first-rate importance both for economic and for strategic reasons. North of the ridge ran the principal French and Belgian coal seam the axis of which in Artois is roughly the line Béthune-Lens. Although the public mind was naturally slow to grasp the fact, nevertheless as soon as it became clear that trench warfare would result in the postponement of a decision, first-class economic objectives, such as the coal-mines, began to increase in general military value and continued to do so until the decisive campaign of 1918.

Strategically, the German lines in Artois covered the Lille-Douai-Cambrai railway, their main transversal line behind all this part of their front. Should this line be cut, were it even brought under effective artillery fire, their railway traffic would be compelled to use the inferior line Lille-Orchies-Somain-Cambrai.

Although the final elaboration of trench warfare was a matter of years, its general characteristics, especially the strain and hardship of remaining immobile and in close contact with the enemy, appeared at once. The possibility of manœuvre disappeared and war became an affair of ever-increasing masses of material. In Artois, the importance of the sector and the nature of the soil made the fighting fierce and continuous and the hardships peculiarly bitter. The clay soil churned into a soft and sticky mud into which men sank deeply and sometimes even were lost. Everywhere the ground was humid; the Lorette ridge itself was honeycombed with springs so that trenches dug even on its summit were difficult to keep clear of water. Weapons often became unserviceable, and the men themselves looked like walking lumps of mud. Nevertheless, the fighting was not only savage but continuous. A major operation was merely a crescendo in a never-ending series of furious lesser combats, all centring about the commanding Lorette-Vimy ridges.

Throughout the first three years of trench fighting on the western front, in most of the minor operations, and in every

major operation except Verdun, the Allies attacked. Save in that one case, the Germans held to their decision to stand upon the strategic defensive in France and Belgium, from Nov. 1914 to March 1918. In order to attempt a decision, it was, therefore, necessary to attack their entrenchments. The strength of the defensive in trench warfare, and the corresponding difficulty of the attack, were realized only with time.

Originally, the entire Lorette ridge was occupied by the Germans during the race to the sea; the French swept them off in a brilliant little attack. Then the Germans moved in again and took the chapel and all the eastern end of the ridge nearly to the wood of Buvigny, not by assault but because the place had been left entirely unguarded during the night of Oct. 7–8 in the course of a relief of the French troops in the sector—an incident altogether typical of the race to the sea. As regular trench warfare began, the Germans had the best of the artillery fighting. Their guns were both heavier and more numerous, and their fire control better suited to the new and unexpected sort of fighting. Their batteries were emplaced near Liévin and Angres, behind Vimy ridge, and behind the butte of Monchy-le-Preux. In Nov. they began to use hand grenades, the first of the typical trench weapons to appear, or rather to reappear. The French did not begin manufacturing grenades during the following winter, and were not able to issue them to the troops until March 1915. Nevertheless, despite the German heavy artillery and grenades, the month of Nov. saw such an improvement in the French defensive works that casualties became fewer, although it was not yet possible to put out continuous wire.

Early in Dec. the situation changed for the better with the arrival of several units of French heavy artillery, whose fire compelled the Germans on Lorette ridge to take cover in their deep dug-outs. The French Higher Command ordered the XXI. Corps, which had held the Lorette sector since its stabilization, to attack in the hope of a break-through. The Corps commander, Gen. Maistre, was doubtful of the success of the operation proposed, judging the means insufficient and the obstacles to be encountered too strong. Nevertheless, the attack took place on Dec. 17 at 1:10 P.M. on a front of a mile and a quarter, with diversions against Auchy-les-La Bassée, and Loos, and in front of St. Laurent-Blangy. Near Lorette the artillery preparation had not been sufficient to prevent the assaulting troops coming under heavy fire, especially from machine-guns, as they left the trenches. The German wire was strong and had been very little cut. Nevertheless, they struggled on through deep mud, and succeeded in taking some trenches. For four days the operation was persisted in. The artillery support was weak, partly because of the winding, irregular front line, partly through insufficient liaison with the infantry. Against such handicaps the infantry strove bravely but in vain. At last, after murderous losses which justified only too well Gen. Maistre's forebodings, the attack was broken off.

An unbroken series of minor operations took place throughout the winter and early spring. In the afternoon of Dec. 27 ten battalions of Chasseurs Alpins, commanded by Gen. Barbot, attacked the hamlet of La Targette, after two hours of artillery preparation. "No-man's-land" was here a quarter of a mile wide, quite flat and without cover save for a single sunken road. Hence losses were heavy and only half a mile of first-line trenches were taken.

As the winter went on, the sticky mud became even worse, and the heavy German trench-mortar projectiles added still more to the danger and discomfort of the trenches. On March 3, at dawn, after a short but violent preparation by heavy artillery and heavy trench mortars, an entire German division made a sudden attack along the crest of the ridge, and drove the French into Buvigny wood. Two days of counter-attacks recovered most of the ground lost, and throughout March and April a series of local attacks and counter-attacks slightly improved the French position at a cost in casualties disproportionately large in comparison with the ground gained. The dead were not all Frenchmen. Already the German troops were beginning to call the ridge "*Totenhügel*," the Hill of Death.

In April the first French 58-mm. trench mortars, few in number, were put in service. The French had already begun the use of hand grenades in March.

About May 1 the French Higher Command decided upon a general attack, and chose Artois as its sector. It was desirable that something be done on the western front in the hope of relieving the pressure upon the Russians, on whose front the great blow was about to fall. The British agreed to support the operation by a diversion in Flanders.

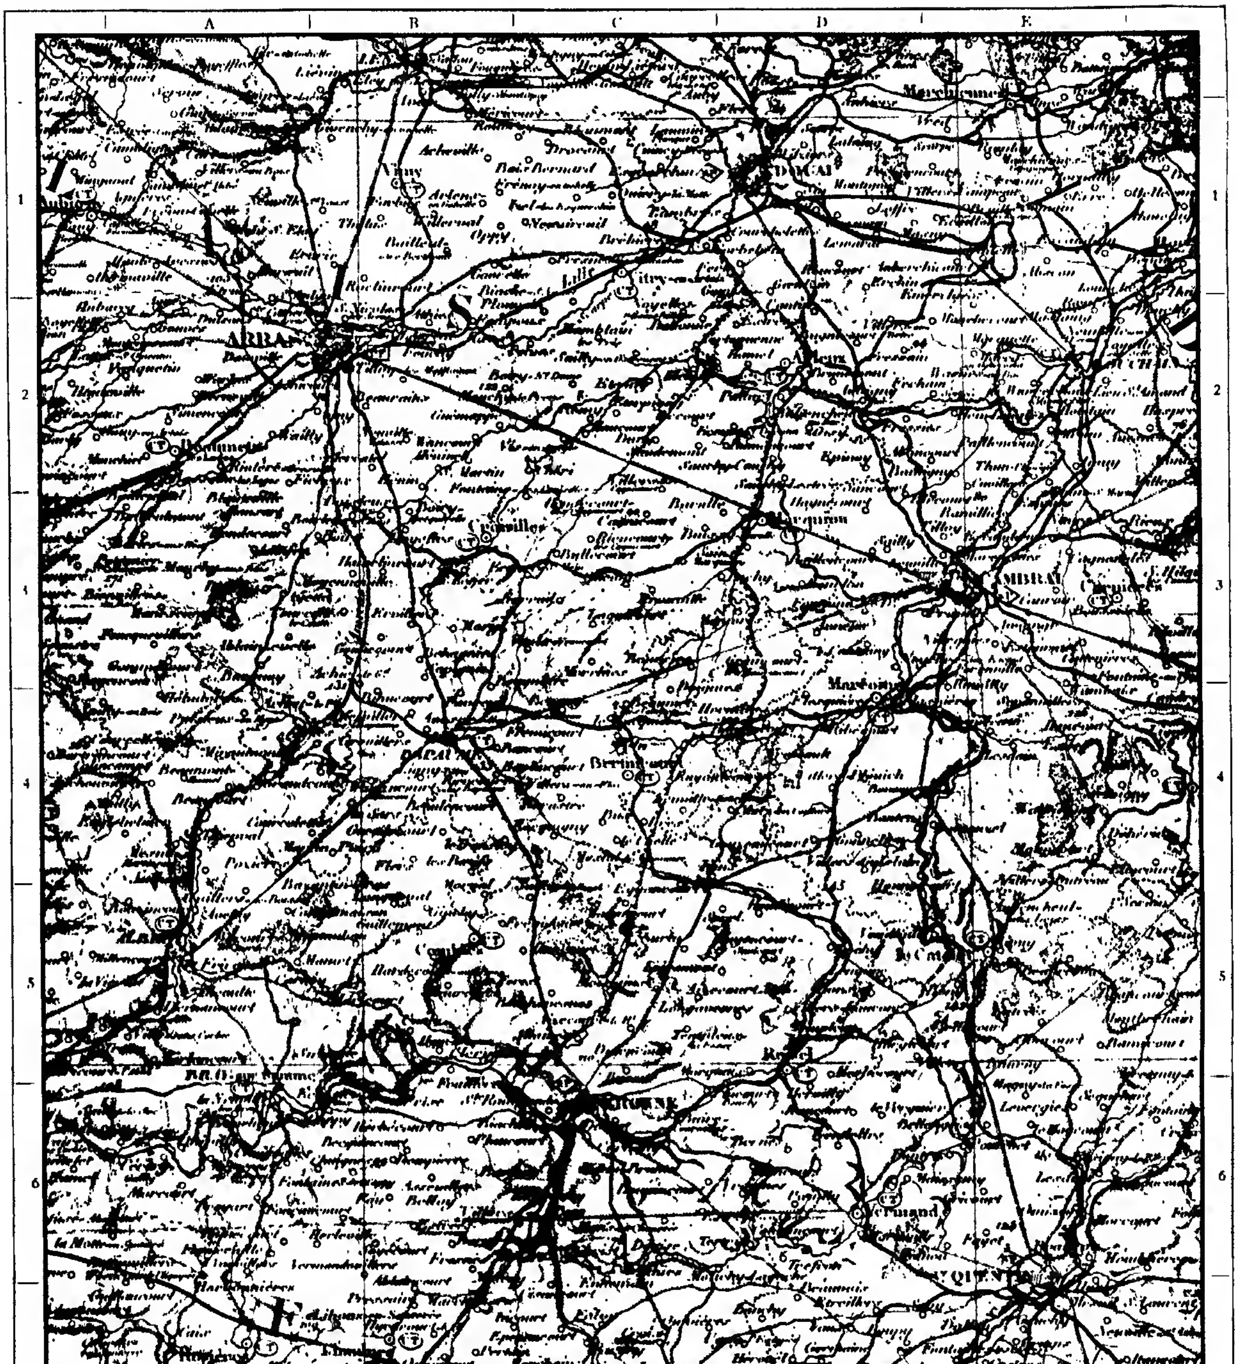
From the original formation of the French "Group of armies of the North," Gen. Foch had been in command. This command he still retained, and his was the decision as to the length of front to be attacked. Even at this early stage of trench warfare, he saw clearly that to estimate the possible width of an assault according to the number of infantry available was nonsense. He therefore insisted upon calculating the front to be attacked according to the available quantity of heavy artillery, insisting that a clear superiority in heavy pieces was necessary over the full width of the operation proposed. On the western front as a whole, the Germans still disposed of superior numbers in this particular arm, so that it seemed impossible to obtain a sufficient superiority of fire over a front of much more than six miles. As a result of Foch's insistence the width of the attacking front was limited accordingly. The right of the proposed assault was fixed in the neighbourhood of Roclincourt, the left on the northern slopes of Lorette ridge. At this stage of the war it was still believed that a violent effort, even on so restricted a front, stood a fair chance of breaking through the opposing trench system and restoring a war of movement.

From May 4, the German Higher Command was convinced that a considerable attack was to be expected. Nevertheless, so high ran their hopes of victory in the east that even Falkenhayn, usually so chary of reinforcements for that theatre, drew yet another division thither from France.[1]

In Artois, the French order of battle was as follows: the left of the XVII. Corps was around Roclincourt. North of them stood the XX. Corps, its left facing La Targette and extending a little north of that village. North of the XX. came the XXXIII. Corps, commanded by Pétain, the future commander-in-chief of the French armies on the western front. His extreme left faced Ablain. North again of the XXXIII. Corps, astride the Lorette ridge and on to the Arras-Béthune high road, stood the XXI. Corps which, always under Maistre, had held the sector from the beginning. The XX. and the XXXIII. Corps had three divisions each, the other corps two. All four corps formed part of the X. Army, now commanded by D'Urbal, who had relieved Maud'huy, the original army commander, in March. Foch shifted his headquarters from Cassel to Frevent on the Doullens-St. Pol road in order to follow the operation more closely. The troops were in high spirits at the prospect of quitting the foul and muddy trenches, and in the hope of fighting in the open thenceforward.

Opposite them, the German defences were formidable; indeed the painstaking German national character is well adapted to the construction of elaborate works. Each of the solidly built French villages was a complicated little citadel. North of Ecurie a huge tangle of trenches formed a strong point, known as the Labyrinth, covering more than half a square mile. A series of works, known to the French as the "Ouvrages Blancs," ran in a concave line from a hummock in front of La Targette to the western end of Carency. On the Lorette ridge itself, the ground favoured the defence. The southern slopes were precipitous and were, moreover, cut by deep ravines which the French likened to the grooves in a melon rind. Of the five spurs between these ravines, the Germans held the easternmost three, their front line running from a point a thousand yards west of the ruins of the chapel, across the summit of the third spur, and so to the western end of Ablain—a curious position which only the great strength of the modern defensive made possible. To the

[1] Falkenhayn, *Die Oberste Heeresleitung*, p. 74. At this period, Falkenhayn says, the total German combatant strength in the western theatre was 1,900,000 against an Allied total of 2,450,000.



Reproduced by permission from the map of France on the scale of 1:320,000, published by the Service Géographique de l'Armée.

north the ground fell away gently in an even slope broken only by the unexpected Buval ravine. The entire German part of the ridge was covered with trenches and obstacles and swept by batteries (at ranges of two to four thousand yards) around Liévin and Angres and behind Vimy ridge.

The troops which held these defences belonged to the German VI. Army which held the front from south of Ypres to within 10 m. of Arras. It comprised 16 divs., at a combat strength of about 17,000 per division according to the reduced German divisional organization dating from the early winter of '14. This gave a little less than three men per yard of front considering the irregularities of the line. Crown Prince Rupprecht of Bavaria commanded the army, with Maj. Gen. Krafft von Dellmensingen for chief-of-staff, and headquarters at Lille.

The attack, originally ordered for May 7, was put off to the 8th and then to the 9th. Demolition fire was begun on the 7th and continued on the 8th, especially against the region of Neuville and the Labyrinth, but was hindered by the lack of all observation from the ground (no commanding points being in French hands), and by the serious imperfections of the aerial observation attempted by planes and dirigibles. The morning of the 9th dawned fair, with a light mist that soon cleared away. At six o'clock an intense bombardment was opened along the whole line from Loos to Arras, with heavy, divisional, and trench artillery. On the front of the XXI. Corps the 75's held their fire until eight o'clock, then began, and continued, at the rate of four shots per piece per minute. Amid the din of the bombardment, the French observers saw the German positions lost in vast clouds of smoke and dust sent up by the exploding shells. The German artillery replied energetically, searching for the French infantry assembled for the assault and occasionally hitting them with considerable effect. At 10 o'clock, precisely, the French artillery automatically increased the range and the infantry attack began.

The assaulting troops left their jumping-off trenches without signal. In a few moments it was clear that both wings were held up. The XVII. Corps could not gain a foot; the wire in front of them was still intact. The X. Corps, attempting a diversion east of Arras, uselessly lost 3,000 men in 10 minutes from machine-gun fire. North of the XVII., the right of the XX. Corps was helpless in front of the wire of the Labyrinth. The left of the XX. was doing better, the wire in front of them having been cut by the bombardment. In spite of heavy losses from German machine-guns still in position, they slowly cleared La Targette, fighting hand to hand, and by 11:30 they had advanced a little over half a mile and reached the westernmost houses of Neuville. On the ridge, the XXI. Corps was advancing only very slowly, at a cost of murderous losses. Their attack was peculiarly difficult to organize for want of a single conspicuous object in their front to serve as reference point for the artillery, and upon which the infantry could align their advance. Their assaulting elements came under heavy machine-gun fire as soon as they showed themselves, so that the communication trenches were obstructed by numbers of wounded who blocked the reserves. Machine-guns firing northward from Ablain made advance impossible along the southern slope. On the plateau itself and the northern slope, swept though they were at short ranges by the German batteries around Angres and Liévin, there was a slow and painful advance of about half a mile, which took three successive lines of trenches and reached, at noon, the neighbourhood of the chapel and the land N.W. of it. Through the morning, the extreme left of Pétain's Corps, the XXXIII., was fixed in front of Ablain. Other units, fighting every step of the way, were slowly working forward south of Carency.

Meanwhile, the right of the XXXIII. Corps had broken clear through the German line. Here, alone on the attacking front, the wooded hill of Berthonval had given good land observation by which to direct the bombardment. The wire had therefore been cleared and most of the machine-guns put out of action. Carrying conspicuous markers to enable the artillery to follow their march, the infantry swept forward without a check. In the intoxication of such an advance after a winter in the abominable trenches, they got out of hand and ran forward, cheering as they rushed the German elements that tried to resist them. They crossed the Béthune road, gained the crest of Vimy ridge, and looked down upon the rolling plain to the north and east, towards Lens and Douai, with no more German troops before them. Hundreds of prisoners had been taken, it was only 11:30, and they had advanced over two and a half miles.

Naturally, the German command was frightened. Partially, at least, they had been surprised, for they had assembled no reserves. Twenty miles away, in Lille, the Prince of Bavaria's staff began packing up, for if the gap could be widened the whole front would go. But naturally, the assaulting troops were completely exhausted. They had run and yelled too much and their water-bottles had been emptied too quickly. During the advance, officer casualties had been numerous. About a mile of the crest between 119 and 140 was occupied, and patrols were pushed forward to Souchez and Givenchy.

Everything now depended upon the arrival of reinforcements. With them everything might be hoped; without them it would be hard to hold the ground already gained, limited as it was by concentric machine-gun fire from Souchez, Neuville, and La Folie wood; and no reinforcements came. The advance had been faster than had been planned, and either the army staff work was slow and the necessary orders not issued in time, or else the units ordered forward failed to make good speed. Perhaps, after all, the thing was impossible. Certainly no good road ran east into the newly created salient. At all events the opportunity was lost.

On the German side, when the first moment of panic had passed, the reaction was rapid. Great and deserved credit was won by the staffs concerned. During the afternoon, enough battalions from the second line of the division near by were scraped together for a counter-attack (supported by artillery behind La Folie wood) which retook the crest. The French-African troops, with most of their officers gone, failed to do themselves justice. All this time Neuville and Carency were holding out, and the XXI. Corps could not clear the Lorette plateau. Towards evening the cemetery south of Souchez had to be abandoned. Through the night, third-line battalions from the neighbouring German Army Corps began to come up. The French maintained themselves with difficulty at the Cabaret Rouge and along the road from Souchez to Neuville. The golden moment had passed.

During the next three days, the French improved their positions in vigorous local operations, taking the débris of Lorette chapel, Carency, and most of Neuville. By June 1 Ablain, the sugar-works west of Souchez, and the south-eastern slopes of Lorette were cleared. June saw the Labyrinth painfully occupied, and a narrow and difficult salient (including a bit of Vimy crest) first thrust out eastward from the Cabaret Rouge and then withdrawn. About the same time the Germans were pushed off the north-eastern slopes of Lorette—their last foothold on that murderous ridge now thickly covered with the dead of both sides.

The diversions attempted meanwhile by the British had failed to affect the general situation.

Tactically, the spring offensive in the Artois had partially succeeded. Twenty-five square miles had been gained, the enemy's local resistances had been beaten down, for some hours his front had been pierced. But strategically, the operation had failed. The German front had been very slightly modified and the Russians had been helped in no way.

During the summer, the usual round of little fights went on, barren of results but endured always with the same spirit. In Aug. trench knives were issued to the French infantry for the first time.

In the autumn, another Entente offensive on the western front was decided upon. The French prepared to attack in Champagne and both French and British in Artois, the French from Neuville to north of Souchez, which large village was,

by this time, laid almost level with the ground; the British from Haisnes to Loos—a far more ambitious effort than previous British trench-warfare operations. The main attack, however, was that in Champagne, Artois being only the scene of a diversion on a large scale.

The troops to be put in motion were Maistre's much-enduring XXI. Corps in front of Souchez, and on their right the XXXIII. Corps, now commanded by Fayolle, in front of La Folie. The French and German Higher Commands were the same, except that Maj. Gen. v. Kuhl was now chief-of-staff at Prince Rupprecht's headquarters.

Tactically, the operation was planned differently from that of May in that the attempt was made to crush the enemy by an intense bombardment prolonged throughout several days and that, therefore, no surprise could be hoped for. Objectives were to be strictly limited.

Accordingly on Sept. 20, with improved ground and air observation, and with guns and munitions available on a larger scale than ever before, there began a bombardment of the German works and rear areas, which continued day and night for five days. On the morning of the 25th the bombardment was intensified. At the same time the Germans began their counter-preparation and succeeded in inflicting some loss on the French infantry in their jumping-off trenches. The fine weather had turned to rain.

At 25 minutes past 12 the infantry attack began. The spirit of the German infantry had been broken by the bombardment so that there was little or no resistance, what little there was being due to imperfect "mopping-up."[1] Meanwhile, the German barrage had been laid down too late, and afterwards ignorance of the situation made their artillery afraid to fire. On the other hand, the rain and the muddy, shell-torn ground made the advance very slow. Not until 5:30 in the evening of Sept. 26 were the ruins of Souchez completely cleared and the line carried a quarter-mile to the eastward.

Meantime, unknown to the French, the German command was passing through a crisis of anxiety. Their reserves had not yet come up and the positions on Vimy ridge were almost without defenders and trains were run at short intervals on the Douai-Mericourt-Rouvray line to simulate the arrival of reinforcements. But the bad weather, the abominable terrain, and the French policy of limited objectives saved the situation for the Germans. On the 27th their reserves arrived and the situation was re-established. The action continued, but although the 28th saw the French lines advanced to include an important redoubt in front of Givenchy, the German front was no longer in danger of being broken, and after the 28th the French broke off the battle.

Early in 1916, British troops relieved the French in the sector, which had seen the longest, and (after Verdun) the most murderous battle of the entire war. The French are said to have had in Artois no less than 100,000 killed. The XXI. Corps alone, by Dec. 1915, lost 80,000 dead or wounded, 18,000 of whom fell in the six weeks from May 9 to June 20. (H. N.*)

(C) Neuve Chapelle.—The objects with which Sir John French attacked the German lines in March 1915 were to obtain a more favourable position for his share in the major operations to be undertaken in conjunction with the French. The fighting of Oct. and Nov. 1914 had left the British right between the La Bassée canal and Armentières in an indifferent position tactically. After gaining a foothold on the ridge which runs S.W. from Lille past Aubers they had been thrust off it into the more or less waterlogged low ground at its foot. To recover this ridge was essential if the German hold on the Lille-La Bassée line was to be effectively shaken and Sir John hoped, moreover, to stimulate his troops whose offensive spirit had found few outlets in the cramping conditions of trench warfare in a swamp. The point he selected for his attack was on the front held by Sir Douglas Haig's I. Army, where the Germans' capture of the village of Neuve Chapelle (Oct. 27 1914) had driven a salient into the British lines. This portion of the British front had always been particularly difficult and costly to hold and a substantial success here might not only gain a footing on the Aubers ridge but render the German positions opposite Givenchy and Festubert untenable.

The attack delivered on March 10 by the 8th Div. (IV. Corps) on the left and the Meerut Div. (Indian Corps) on the right was successful in effecting a surprise. There had been no long preliminary bombardment to give warning of the attack, for the ammunition supply only sufficed for 35 minutes' shelling, and the infantry, finding the wire well cut except at the extreme ends of the line, stormed the positions with ease. The 25th Bde. of the 8th Div. carried Neuve Chapelle village and joined hands with the Gahrwal Bde., who had overrun the ground between the village and the cross-roads S. of it known as "Port Arthur." Many prisoners were taken, and it seemed that reinforcements had only to push on to achieve a substantial advance. Unfortunately, the stubborn resistance of the Germans at the ends of the line absorbed the attention of the troops in immediate support. On the left, S. of the ruined farm known as "the Moated Grange," the 2nd Middlesex were held up by wire, which a fold of the ground had concealed from the artillery-observing officers; on the right at Port Arthur a strong point held out for several hours, and was only carried when the 2nd Seaforths of the Dehra Dun Bde. reinforced the original assailants of the Gahrwal Brigade. Similarly, it was not till well past midday, and after heavy fighting, that the 23rd Bde., improving the lodgment made by their right battalion, the 2nd Scottish Rifles, secured their second objective, and then only by utilizing two battalions of the 24th Bde. as well as their own supports, the 2nd Devons and 2nd West Yorkshires. Meanwhile the 25th Bde. had cleared Neuve Chapelle but found their left too much exposed to allow any advance beyond the village. More important still, the orders had been explicit that the reserves were not to be put in without sanction from the Corps, and the extreme difficulty of maintaining communications with the advanced troops prevented divisional and corps headquarters from keeping in touch with the progress of the attack and delayed the advance of the reserves. Not till the afternoon was well advanced did the leading troops of the 7th Div. pass through the 8th, and though the 21st Bde. then cleared a substantial area N. of Neuve Chapelle and made some progress down the German trenches beyond the Moated Grange, German reinforcements both of men and guns made their presence felt, and darkness stopped the advance before the road running N.W. from the Moulin du Piètre past Mauquissart had been crossed. On the right, meanwhile, two Gurkha battalions of the Dehra Dun Bde. pushed forward into the Bois de Biez, but their position was dangerously isolated and they had to be withdrawn E. of Rivière des Layes.

The chances of substantial progress on the second day, already diminished by the arrival of strong German reinforcements, were further reduced by weather conditions which made aerial direction of the British artillery fire impossible. This, combined with the interruption of telephone communications between the forward observing officers and their batteries, prevented the coöperation between artillery and infantry needed to reduce the numerous machine-gun posts furnished by the houses which studded the area N. of Neuve Chapelle. Groups of these, especially along the Moulin du Piètre-Mauquissart road, proved most formidable obstacles. Moreover, the Germans, besides throwing in all the local reserves of their VII. Corps, together with the 6th Bavarian Res. Div. which was resting near Lille, brought up much additional artillery, so that the 7th and Lahore Divs. came under heavy fire and suffered severely in crossing ground in rear of the advanced troops, sometimes without even reaching the front line. The 7th Div. beat back counter-attacks and added considerably to

[1] This process, called by the French "nettoyage" and by the British "mopping-up," was the clearance, by troops specially detailed for the purpose, of the enemy trenches that had been reached and passed by the leading troops of the attack but might—and in practice usually did—contain scattered but intact and dangerous groups of the enemy.

the tale of prisoners, but made no real progress; the 8th could do no more, but until the right of the 8th Div. could come forward to cover it the Indian Corps could not tackle the Bois de Biez.

On the next morning (March 12) violent counter-attacks against several points made it obvious that strong German reinforcements had come up. Advancing in mass against the Bareilly Bde. along the Rue du Bois and against the rest of the Meerut Div. N. of Port Arthur, the Germans were mown down in numbers without ever reaching the British line. Opposite the Moulin du Piètre another determined attack broke through the 24th Bde., to be thrown back by a prompt counter-stroke by the 1st Worcesters; and in this quarter also very heavy losses were inflicted on the Germans. Further N. again the 21st Bde. lost some advanced trenches, but successfully maintained its main position and lent effective aid to the 2nd Scots Guards and 2nd Borderers of the 20th Bde., who carried a strong redoubt N.E. of the Moated Grange and took 300 prisoners of the VII. Corps. But still the Moulin du Piètre-Mauquissart road barred any advance, and the machine-guns in the fortified houses held up all attempts to get forward. Thus, though the 25th Bde. repulsed several attacks they could not carry the line forward from Neuve Chapelle; the Sirhind Bde. (Lahore Div.) made a little ground and took prisoners but could not cross the Rivière des Layes; and now that all advantages of surprise had gone Sir John French saw that little was to be gained by pressing the attack. March 13 therefore saw the fighting much diminished in intensity; gains were consolidated and the troops reorganized, but the attack was suspended.

The battle of Neuve Chapelle ended therefore somewhat disappointingly. The substantial advance which had at one moment seemed within reach had not been realized: the delay in pushing the British reserves had allowed the Germans to rush to the danger spot reinforcements sufficient to bar the road to the high ground of the Aubers ridge. Thus while the tactical position round Neuve Chapelle was much improved the strategical situation was unchanged. The losses, over 4,200 in the Indian Corps, nearly double that in the IV., had been heavy, while of three minor operations undertaken as diversions those at Givenchy (I. Corps) and Wytschaete (II. Corps) failed, only the III. Corps proving successful against l'Epinette (S.E. of Armentières). Still, it would be wrong to class Neuve Chapelle among British defeats. The troops were undoubtedly encouraged by seeing that German positions could be stormed and the captured ground held against powerful counter-attacks. Nearly 1,700 prisoners had been taken and the German losses had exceeded the British. Rifles, artillery and machine-guns had found splendid targets, and the German battalions who had shown themselves in the open had been shot down in masses. It was felt that another attack in which the lessons of the battle could be turned to good effect might lead to far-reaching results.

(*D*) Aubers Ridge and Festubert.—The part assigned to the British in the Allied offensive of May 1915 gave them as their immediate objective the S.W. end of the Aubers ridge. The IV. Corps was to attack at Rougebancs, N.E. of Neuve Chapelle, using the 8th Div. in the first assault and supporting it with the 7th, while S.W. of Neuve Chapelle the Meerut Div. (Indian Corps) and the 1st Div. (I. Corps) attacked from the line of the Rue du Bois which joins the Estaires-La Bassée road at the "Port Arthur" cross-roads. It was hoped that these divisions pushing forward in an easterly direction would establish touch behind the Bois de Biez with the IV. Corps advancing southward past Aubers. But whether successful or not in their immediate tasks, the British would materially assist the Allied operations if their attack diverted German guns and men from the crucial point N. of Arras where the French were attacking.

It was with the greatest confidence that the British forces looked forward to this attack. Neuve Chapelle had whetted their hopes; it was believed that at this second attempt the lessons of Neuve Chapelle would be turned to good effect, that the causes which had robbed that attack of greater success would be avoided, that the increased artillery and ammunition available would allow of a far more effective bombardment. Unfortunately, the delays in renewing the attack, due partly to weather conditions but even more to the insufficient ammunition supply, had given the Germans time to so strengthen their positions that only the heaviest artillery could produce any substantial effect upon them. Parapets, many feet in thickness and backed up by concrete, were proof against 18-pounders, and afforded complete protection against anything short of a direct hit to the machine-guns placed in pits sited at the ground level which swept the "no-man's-land" with a grazing fire. It was only the bitter experiences of May 9 which revealed how very formidable the German defences had become and what an increase in battering-power would be needed to reduce them.

The actual attack delivered early on May 9 met with modified success at Rougebancs, but with complete failure at Rue du Bois. Here the infantry found the enemy's trenches strongly manned; the machine-guns from their pits at the base of the parapets maintained a deadly fire; scarcely any of the assailants managed to reach the enemy's parapets, and the few who did get into the German lines were promptly overwhelmed. Moreover, the German artillery at once opened a heavy counter-bombardment, and the British supports and reserves, packed into crowded communication and assembly trenches, suffered severely, while the task of evacuating wounded and reorganizing the troops for a second attempt proved extremely difficult. A second effort was, however, made by both the 1st and Meerut Divs. about 7 A.M., though without success; and when in the course of the afternoon the Bareilly Bde. of the Meerut Div. and the 1st Bde. of the 1st Div. were put in, the same result followed. A handful of the 1st Black Watch made a lodgment in the enemy's trenches, but so small a party was powerless and was speedily overwhelmed.

At Rougebancs the right brigade of the 8th Div., the 24th, failed except at one point to reach the enemy's trenches, and suffered very severe losses. On its left, however, the 2nd Rifle Bde. and 1st Royal Irish Rifles of the 25th Bde. captured a considerable frontage, and lodgments were also made by the 2nd Lincolnshires and the 13th (Kensington) London Regiment. However, consolidation proved exceedingly difficult. Machine-guns on the flanks, which could not be located or silenced, prevented the advance of reinforcements; efforts to dig communication trenches came under heavy shelling, and could not be completed before German counter-attacks, vigorously pressed and well supplied with bombs, drove back those assailants who had penetrated beyond the front trenches and gradually forced the survivors out of the positions they had captured. The Rifle Bde. held on longest, keeping the Germans at bay till after midnight, but before the 7th Div. could push a battalion across to relieve them a renewed counter-attack ousted them from the German trenches. The division's losses came to over 4,500, about the same as at Neuve Chapelle, but without the satisfaction of retaining any of the ground won at the first assault. The 1st Div. lost nearly 4,000 men, the Indian Corps had over 2,000 casualties, and the completeness of the failure was the more felt because of the high hopes so generally entertained.

However, though the French attacks had also fallen short of the success anticipated, they had gained some ground and were being continued. Sir John French therefore determined to renew his efforts to assist his allies, though on a less ambitious scale. North-east of the village of Festubert the German lines running northward from Givenchy turned N.E. at a sharp angle towards the Bois de Biez, making a salient which it was proposed to attack on two sides. On the night of May 15–16, therefore, the I. and Indian Corps renewed their attempt to advance from the Rue du Bois, using the Meerut and 2nd Divs., while the 7th Div., which had been transferred from the IV. to the I. Corps, attacked eastwardly from Festubert. The attack was preceded by an intermittent bombardment extending over several days, instead of the short but intensive bombardment employed on March 10 and May 9. Over a large part of the

front attacked the German wire was effectively cut, but opposite the Indian Corps the German parapets successfully defied the efforts of the British artillery and (on the left of the front attacked) the Meerut Div. and the left of the 2nd Div. failed to carry the hostile trenches. The rest of the 2nd Div. fared better; the 6th Bde. and part of the 5th stormed the front German line, and reinforced by their reserves began pushing on against the second line. At 3:15 A.M. on May 16 the 7th Div. attacked, while the Meerut Div. made a fresh attempt. Once again machine-guns sheltered behind Lille damaged parapets and shot down the Gahrwal Bde., and this failure affected the advance of the division, who had to establish a defensive flank on their left and to devote their main efforts to getting touch with the 2nd Div. whose attack had met with considerable success, especially in the centre, where the 2nd Scots Guards and 1st Royal Welsh Fusiliers had penetrated deep into the German positions. On their right also the 2nd Queen's, after a temporary check, had got well in, and while they pushed on towards La Quinque Rue a bombing attack down the German front line, S. of the point of entry, led to the clearing of 700 yd. and the capture of 200 prisoners. But casualties had been heavy, and on the left the stubborn resistance of a strong point held up the left of the 20th Bde., which exposed the flank of the most advanced parties. These, out of touch with their supports, were forced back by counter-attacks. Similarly, the progress of the 2nd Div. was retarded by the resistance of two fortified farms, Cour d'Avoué and Ferme du Bois. Until these strong points could be reduced substantial progress was impossible.

Next day (May 17) operations were continued, a special effort being made to close the gap between the 2nd and 7th Divs., after which it was hoped to push on towards Rue d'Ouvert and Chapelle St. Roch. The first of these objects was effected, after about 700 Germans in the angle between the two attacks had left their trenches, apparently intending to surrender, but had been shelled by their own guns and almost wiped out. But the Ferme du Bois held up the 2nd Div., which could only progress to some extent on its right. The 7th Div. started well and cleared the strong points which had checked the left of the 20th Bde., but could not get much further in the direction of Cour d'Avoué, while the efforts of the 2nd Bedfords and 4th Camerons to push on against Rue d'Ouvert were not in the end successful. On May 18 the 4th (Guards) Bde. attacked Cour d'Avoué from the W., but could not carry it, and Canadian infantry, who on that day began relieving the 7th Div., did not succeed in doing more than master an orchard which had been reached (but lost again) on May 16 by some of the 7th Division. By this time the Germans had brought up considerable reinforcements and many machine-guns, and as the ammunition available was nearly exhausted all chance of substantial success seemed gone. For another week, however, severe fighting continued between La Quinque Rue and Givenchy, the brunt falling on the Canadians and on the 47th (London) Div. who were holding the Givenchy sector. These operations resulted in the capture of several hundred yards of trenches, including two formidable strong points, and the repulse of several German counter-attacks, but by May 25 Sir John French found it necessary to call a halt. It was now clear that though the great French effort further S. had won much valuable ground it had failed to break the enemy's line or to prove the decisive stroke that had been hoped for: the Allies had to resign themselves, therefore, to a suspension of active operations. Actually, it was not till the end of June that this became complete, and in the interval two minor attacks were made near Givenchy, one by the 7th and 51st (Highland Territorial) Divs., the other by the Canadians: neither, however, resulted in any appreciable gain of ground, and although on June 16 an attack by the 3rd Div., now in the V. Corps, carried some German trenches W. of the Bellewaarde ridge and improved the tactical situation in the Hooge neighbourhood, it did not lead to the recapture of Hooge and involved the assailants in heavy losses.

For three months, therefore, the position on the British front was one of almost complete stagnation. The only events of real importance were the arrival of the long-expected "New Army" divisions, the first of which, the 9th (Scottish) Div., actually began its disembarkation at Boulogne on the day of the disastrous repulse at Fromelles and Rue du Bois. By the end of July eight of these divisions were in the country, and their presence permitted the formation of a III. Army, which took over from the French a line to the N. of the Somme between Arras and Albert. During this period there was of course intermittent activity on the British front, mainly in the Ypres salient. Here at the end of July the Germans, making use for the first time against the British of their *Flammenwerfer* (liquid-fire projectors), attacked and captured the right trenches of the 14th (New Army) Div. just S. of Hooge. The battalion holding the trenches was overwhelmed, and a counter-attack next day was unsuccessful. Ten days later, however (Aug. 9), two brigades of the 6th Div. made a fresh attempt after careful reconnaissance and preparation. The German position was carried on a front of 1,000 yd., and heavy losses were inflicted on them; they brought up large reinforcements and strove desperately but unsuccessfully to regain the ground, but the 6th Div. held firm, retaining the trenches lost in the *Flammenwerfer* attack with a small spur N. of the Menin road.

It gives some indication of the difference in scale between the war of 1914-8 and the greatest of the previous campaigns of the British army that the 1,800 casualties of the 6th Div. in this quite minor action exceeded by 50% the losses of Wellington's army at Busaco.

(*E*) Loos.—If in the Allied offensive of Sept. 1915 the British army, as in May, played only a subsidiary part, its contribution far outstripped both in men and in materials the meagre preparations of May. A four days' bombardment on a scale hitherto unprecedented preceded the attack, for which nine divisions were available as against the four of May 9, while six others contributed by undertaking diversions. The frontage attacked extended over nearly 6 m., from just S. of the mining village of Loos on the right to the La Bassée canal on the left. The line ran fairly straight from S. to N. for nearly 3 m., but then curved away in a N.W. direction towards Cuinchy, so that two of the three divisions of Sir Hubert Gough's I. Corps on the left had to attack N.E., while the right, Sir Henry Rawlinson's IV. Corps, was striking due east. Further, Gough's left division, the 2nd, was to attack on both sides of the canal, the 5th Bde. from Givenchy-les-La Bassée, the 6th and 38th Bdes. from Cuinchy. The 5th Bde.'s attack was one of the operations intended to distract the enemy and divert his reserves, but the other brigades aimed at reaching Auchy and linking up near Haisnes with the left of the main attack. A defensive flank would thus be established, under cover of which, and of a similar flank to be formed on Rawlinson's extreme right by the 47th Div., the central divisions of the I. and IV. Corps with the XI. Corps in support and the cavalry in readiness behind, would, it was hoped, break through between Haisnes and Loos, reach the Deule canal at Port à Verdin and unite E. of Lens with Gen. Foch's troops.

To improve the chances of success and introduce an element of surprise it had been decided to employ against the Germans their own device, gas. Elaborate preparations had been made for the use of this weapon, and on its expected effectiveness in surprising and demoralizing the defenders the highest hopes were based.

The operations to be undertaken as diversions were much more substantial in scale than those which had accompanied the Neuve Chapelle attack. The 19th Div. was to attack in the low ground E. of Festubert. North of Neuve Chapelle the Indian Corps, supported on the left by the 20th Div., was to assault the German salient at Mauquissart, the legacy of the Neuve Chapelle fighting. Further N. again the 8th Div. was to attack at Bridoux, while the principal diversion was that to be undertaken against Hooge and the Bellewaarde ridge on the Ypres front by the 3rd and 14th Divisions. These attacks were more than mere raids; they all aimed at definite tactical improvements in the local situations, but their primary object was to

prevent the transfer of reserves to the main point of attack. This object they achieved, even if they nowhere resulted in permanent gains of ground, for it was only by prompt and vigorous use of reserves and hard fighting that the Germans recovered their initial losses at Hooge, at Bridoux and at Mauquissart where the Indian Corps made a fine fight.

In the preliminary bombardment the field guns were employed to cut the wire, while the heavier guns battered the other defences. Considerable damage was inflicted both on the trenches and their garrisons, though in places deep dug-outs allowed the defenders to escape lightly. Most of the wire was effectively destroyed, but at several points folds of the ground concealed it from observation, and at two at least this had far-reaching effects, parts of the attack, which was delivered at 6:30 A.M. on Sept. 25, being held up by uncut wire. Moreover, the wind proved too weak to carry the gas forward quickly, and thus made it in places worse than useless. This was notably the experience of the 2nd Div. at Cuinchy, and its attack, though gallantly pressed, proved unsuccessful and costly. Better success attended the 9th Div. E. of the railway to Vermelles, though its left brigade, the 28th, found the wire practically intact and was repulsed with heavy losses, a second attack by the supporting battalions faring no better. The 26th Bde. had to assault the formidable and important Hohenzollern Redoubt, which protruded in front of the slag heaps and miners' cottages at "Fosse 8," S. of Auchy. With great gallantry and at a heavy cost the Highlanders carried the Redoubt and swept on over the German main line, clearing the cottages and slag heaps behind. Some of the supports were absorbed in securing this first objective, but the remainder pushed forward and established themselves just short of Haisnes in the Pekin trench, part of the German second line. With prompt support Haisnes might have been carried, but the 27th Bde. were much delayed by the returning wounded and German prisoners who crowded the communication trenches, and before its leading battalions could reach the front the opportunity had passed; German reserves had arrived. All the 9th Div. could attempt was to maintain its gains against the counter-attacks.

Opposite the 7th Div. the chief tactical feature was a group of quarries W. of Cité St. Elie. These were reached and taken by the 22nd Bde., but at a cost which left it too weak to carry its second objective, Cité St. Elie. The 20th Bde., however, penetrated much deeper into the German position, capturing eight guns, and reaching the cross-roads between Cité St. Elie and Hulluch. But it was out of touch with the 22nd Bde. on its left, and as the division's reserves, the 21st Bde., were partly absorbed in consolidating the quarries sufficient reinforcements were not forthcoming to carry the attack any further. Thus despite its substantial initial success the advance of the I. Corps came to a standstill. The detachments which had established themselves in the German second line were scattered and isolated, and needed both reinforcements and artillery support. But information was scanty and slow to get back to headquarters and without accurate information artillery support was impossible; the immediate reserves had been used up, and as no more were forthcoming the opening could not be exploited.

On the left of the IV. Corps the 1st Div. had as its objective the line from Hulluch to Bois Hugo, N.E. of Loos. Its left brigade, the 1st, was most successful: it stormed the front line and pushed on to Hulluch over several lines of trenches, capturing three guns. But here it found itself unsupported, for the 2d Bde. on its right had been stopped by uncut wire several hundreds of yards long and its repeated assaults proved equally unsuccessful and costly. The reserves of the 1st Div. had, therefore, to be used against its first objective, and not till the afternoon were they able by crossing the German trenches on the flanks of the untaken portion to compel its defenders to surrender. By the time, therefore, that the 2nd Bde. finally reached its objective at Bois Hugo the delay had had serious consequences: the 1st Bde. had already been forced back 500 yd. from Hulluch, and the left flank of the next division to the right, the 15th, had been insecure all day.

Nevertheless, the 15th Div. had achieved remarkable success. Attacking with the 46th Bde. on the left and the 44th on the right, it carried the German front line, swept on over a second trench system into Loos and through it, and pushed on over "Hill 70," E. of Loos, until brought up by the defences of Cité St. Laurent, one of the suburbs of Lens, and by a railway embankment farther north. But their rapid advance had carried the men beyond the reach of artillery support; mixture of units had destroyed cohesion, and touch had been completely lost with the headquarter formations in rear. Moreover, though some of the 46th Bde. had reached and occupied Puits 14 bis, a mine S. of Bois Hugo, the 2nd Bde.'s failure had left the 15th exposed to counter-attacks from the N., and reserves which might have secured the advanced position had to be diverted to that flank. On its other flank, however, the 15th Div. had no cause for anxiety. The 47th (London) Div. had as its task the formation of a defensive flank from the S.E. of Loos back to the British front line. This task it had accomplished to the letter, capturing three guns and several hundred prisoners, and after consolidating all its objectives it maintained them against vigorous counter-attacks.

About noon, then, on Sept. 25 the prospects of a break-through seemed bright. If reserves could have been promptly pushed in, the arrival of German reinforcements might have been forestalled and the advanced troops not only supported but carried farther forward. Unluckily, neither Gough nor Rawlinson had reserves available, and at noon the leading troops of the XI. Corps were still 3 m. from the original German front line and had to thread their way forward through an area congested with transports and with traffic of every description. More guns meant larger ammunition columns, while additional machine-guns meant additional limbers, and the rapid expansion of the British army had not only meant increased impedimenta but had brought into staff posts many officers without staff training or experience. The congestion of the rearward areas was a serious handicap, but hardly to be wondered at.

By the time the leading units of the XI. Corps reached the front matters had already changed for the worse. At nearly every point German counter-attacks had thrust back the most advanced troops, and though the Germans had had to pay heavily for their gains the fact that their reinforcements were arriving in strength was even more serious than the loss of ground. At Hill 70 in particular there had been desperate fighting, and only with great difficulty had the 15th Div. maintained a position on its western slopes, thanks largely to the initiative of a battalion commander who, arriving there after the advance had swept on over the crest, had promptly entrenched a position on which the remnants of the advanced troops were able to rally when the counter-attack drove them back. But now that the XI. Corps was up it was hoped to push on again next morning.

The plan for Sept. 26 was that the IV. Corps, reinforced by the 21st and 24th Divs., should renew the attack from Loos to Hulluch. As a preliminary portions of the 15th and 21st Divs. were to recover the crest of Hill 70. However, as their attack started the Germans began a series of heavy counter-attacks from Bois Hugo southward, and succeeded in driving out of Bois Hugo the brigade of the 21st Div. which had just relieved the 2nd Bde. there. Profiting by this they pressed in on the left flank of the 15th Div. and gradually forced it back. Farther S. the efforts of the 45th and 62nd Bdes. to carry Hill 70 were held up by wire which the Germans had rapidly put up, and by a redoubt on the crest. Moreover, when the main attack was delivered it was mainly by enfilade machine-gun fire from Bois Hugo that the 24th Div. was repulsed and driven back. All efforts of the 21st Div. to recover Bois Hugo failed; the 1st Div. could effect nothing by itself, and it was largely the possession of Bois Hugo and of Puits 14 bis which finally enabled the Germans to thrust the defenders of Hill 70 down the hill in upon Loos. That village, however, was secured by the arrival of the 6th Cav. Bde., and N. of Bois Hugo the Germans did not attempt to advance beyond the La Bassée road.

To the I. Corps also Sept. 26 had brought disappointment. Shortly before midnight (Sept. 25-26) a German attack broke through at the junction between the 7th and 9th Divs. and penetrated into the quarries, which passed back into German hands, the left of the 7th Div. recoiling to the old German support trenches. On its right the 7th Div. maintained all but its most advanced positions, and linked up with the 1st in front of Hulluch, but two attempts to recover the quarries failed. At Fosse 8 the 73rd Bde. of the 24th Div. (which had relieved the 26th Bde.) had great difficulty in holding its ground against counter-attacks. Fosse Alley, however, the intermediate line between the front system and Haisnes, which had been evacuated when the quarries were lost, was reoccupied and held by the 27th Bde., and the Germans had to pay highly for such ground as they regained. But they had now brought up several fresh divisions, and pressed their attacks hard, especially against the inexperienced 73rd Brigade. Before midday on Sept. 27 these troops, short of ammunition, food and water, and quite unable to reply effectively to the German bombers, were driven out of their positions. A dashing advance by the remnants of the 26th Bde. prevented the loss of the Hohenzollern, which had seemed imminent, but the recapture of Fosse 8 and the dump made Fosse Alley untenable and compelled its evacuation. Against the 7th Div., however, the Germans were less successful, and Sept. 27 saw the right of the position of the I. Corps fairly satisfactorily consolidated.

While the I. Corps had been defending its gains, the IV. had been striving to make more. During the night of Sept. 26–27 the Guards Div. had relieved the 21st and 24th opposite Hulluch and Bois Hugo. On the afternoon of the 27th its 2nd Bde. attacked Bois Hugo and Puits 14 bis, while its 3rd advanced through Loos against Hill 70. Both attacks were splendidly pressed and achieved valuable gains. Chalk Pit Wood was reached and secured, though Puits 14 bis could not be held against heavy counter-attacks, and a line was established just W. of the La Bassée road to link up with the 1st Div. opposite Hulluch. Similarly the 3rd Guards Bde. put Loos out of danger of recapture by making good a line just below the crest of Hill 70.

By the evening of Sept. 27 all hopes of a speedy and decisive success were gone. No break-through had been achieved, and Gen. Foch's attack also had been checked. Still the vigour with which the Germans hurled counter-attack after counter-attack at the positions taken from them testified to the value they attached to them. The fighting was fiercest round the Hohenzollern Redoubt, which the 28th Div. took over from the 9th on Sept. 28 and held under considerable difficulties till Oct. 3, when a specially violent attack drove them from its ruins, though even then they retained a substantial portion of the 9th Div.'s gains of Sept. 25. On Oct. 5 the Guards relieved the 28th Div., and during the next week made several minor gains by bombing-attacks. Fighting was also heavy without producing any marked change in the tactical situation round the quarries on the frontage held in succession by the 7th, 2nd and 12th Divisions. From the Vermelles-Hulluch road to Loos the Germans were less aggressive, their only serious effort on this front being on Oct. 8, when they attacked in great force, only to be repulsed with very heavy losses especially by the 1st Div. at Chalk Pit Wood and by the French, who had taken over Loos itself on Sept. 30.

After this repulse the Germans made no more big counter-attacks. By recovering the dump and Fosse 8 they had won back observation posts which overlooked much of the salient which the battle had produced. Sir John French was naturally loth to abandon the effort to recover them, and decided to bring up the 46th (North Midland) Div. for a fresh attack on the Hohenzollern Redoubt, while simultaneously the 12th and 1st Divs. should attack the quarries and Hulluch. The attack, delivered on Oct. 13, was only partially successful, but did result after heavy fighting in the recovery and retention of the bulk of the redoubt. The 12th Div. failed to retake the quarries, but made useful gains which improved its line. The 1st Div., however, once again found Hulluch too much for it, so that the net result of the attack did not encourage a repetition, and with this major operations in the battle area ended. The French continued attacking in Champagne for some weeks, though even there all prospect of decisive success was gone, while in Artois they had already abandoned their offensive.

When the results of the British offensive are set against the high hopes entertained before the attack it is excusable to write it down as a failure. The gain of ground was not worth the 50 to 60 thousand casualties incurred in its capture, but the German losses on the British front were almost as heavy, and the capture of over 20 guns and 3,000 prisoners was no small encouragement. It had been shown that the Germans could be driven from positions they believed impregnable. Moreover, valuable experience had been gained not only in the use of the new weapon, gas, but in staff work, in administrative arrangements and in tactics, experience to be turned to good account in 1916. At Loos an effort had been made to apply the lessons of Neuve Chapelle. It was partly because Neuve Chapelle had shown the dangers of retaining too close a hold on the immediate reserves that it had been arranged that the troops (immediate reserves included) were to press forward without limitation. Loos showed the advantages of the "limited objective" and of dealing with untaken portions of a hostile line rather by outflanking them than by renewing direct attacks; it also showed that the patterns of grenades in use in the British army were too varied and mostly unsuitable for wet weather, with other lessons major and minor. It is easy in the light of the experience gained at and after Loos to criticize the whole plan as too ambitious for the resources, human and material, at the commander-in-chief's disposal; to point out the unwisdom of employing raw troops in a great battle within a fortnight of their landing in France; to argue that, had the frontage attacked been narrower and the divisions disposed in greater depth, more immediate reserves would have been available. Still the balance remains on the side of gain. Loos inflicted heavy losses on the Germans; it was a foretaste of heavier losses in store for them. The performances of the 9th, 12th and 15th Divs. showed that the improvised "New Armies" of Britain were likely to prove a factor of decisive importance in the war.

(C. T. A.)

(*F*) The German Retreat to the Hindenburg Line, 1917.—In order to follow intelligently the operations which took place during the early part of 1917 it is necessary to understand thoroughly the situation which had arisen and the general atmosphere which had been created as a result of the prolonged fighting on the Somme. In Dec. 1916, Gen. Nivelle was appointed to the chief command of the French forces. He declared great confidence in his ability to break through the enemy's defences by the delivery of a mighty blow specially prepared, and immediately disclosed his project to the British commander-in-chief, Sir Douglas Haig. The plan was briefly as follows: (*a*) to deliver the main attack by three French armies on the Aisne front—one of these armies to be in reserve for purposes of exploitation; (*b*) to deliver a subsidiary attack by the British army on the Arras front; (*c*) to undertake minor actions between Reims and Arras to contain the enemy; (*d*) vigorous exploitation. In order to give effect to these proposals and to enable the French to undertake the major operations with large reserves, Gen. Nivelle's plan included the relief of French troops by the British as far S. as the Amiens-Roye road. The weakness of this plan, apart from the Russian revolution and release of German reserves, which could not be foreseen, lay in the imposition of the major task on the French armies, already exhausted by two years of heavy fighting and the strain of the defence of Verdun, while the British, at the height of their strength and vigour, instead of being trained and concentrated for a vigorous blow, were relegated to defensive work and the minor rôle. These operations were to take place as early as possible, and it was hoped that the respective attacks would be launched early in April. The Somme battles had evidently shaken the enemy seriously, and had caused his defensive front

in the neighbourhood of the Ancre to become a pronounced and dangerous salient. Moreover, it was known that he was constructing a rearward line of defence, subsequently known as the Hindenburg Line, which would materially shorten his defensive front and thus release a number of divisions which could be moved into reserve.

Such was the position of affairs on Jan. 1 1917. The maintenance of pressure on the enemy on the Ancre-Somme battlefront was now of immediate importance. Signs were not lacking that the enemy had considerably weakened, and his position in the Ancre salient was vulnerable and dangerous. After a period of bad weather it became possible during Jan. to undertake minor and local operations, which resulted in the capture of the Beaumont Hamel spur, thus opening up a wide field of view and observation for artillery fire. No time was lost in making use of this advantage. Indeed, it was essential to engage the enemy closely, whether it was his intention to retire voluntarily to some previously prepared position, or whether his defence was involuntarily weakening. The country on both banks of the Ancre consists in pronounced undulations with spurs running towards the stream from both north and south. Opportunity was offered for skill in the handling of comparatively small bodies of troops, in making use of the ground, and of coöperation both by movement and by fire. Making use of the tactical advantage obtained by possession of the Beaumont Hamel spur, the 63rd Div. carried out a successful operation early in Feb. which carried the British front forward on the N. bank of the river. This assisted towards the capture of a point on the S. bank, which gave observation into the upper valley of the Ancre and over the German gun positions. These hostile batteries which protected the Serre salient were forced to withdraw, thus weakening to a dangerous degree the German defences to the north. It was now possible to attack with advantage the Serre-Beauregard and Courcelette-Miraumont ridges, the possession of which, besides turning the German defences on the N. in the neighbourhood of Gommecourt and Monchy, would open up a further field of view up the valley of the Ancre, where many hostile batteries had been located. In order to gain this position an assault was delivered on the morning of Feb. 17 by the 2nd, 18th and 63rd Divs. on both banks of the stream. On the N. bank the attack was completely successful, while on the S. bank considerable resistance was encountered. Nevertheless, the whole position was occupied shortly afterwards, and small detachments and patrols working forward succeeded in occupying the enemy's defences on a wide front from opposite Guedecourt to Serre, including the villages of Warlencourt and Miraumont as well as the Beauregard spur.

It had become increasingly evident that the German defence was weakening, and their troops were being gradually withdrawn, the first indications being on a narrow front in the valley of the Ancre, but now on a more considerable scale. The prolonged period of exceptional frost following on a wet autumn had frozen the ground to a great depth. The thaw, however, began in the third week of Feb.; the roads, disintegrated by the frost, now broke up, and the area of the 1916 battlefield became a quagmire. On the other hand the conditions of the weather favoured the defenders, who fell back on to fresh unbroken ground, and the succession of misty days covered their movements.

Notwithstanding these difficulties the British and Australian troops kept up constant pressure, and by the delivery of minor attacks drove the enemy from position to position, until by the end of Feb. the whole of the Ancre valley and the higher ground to the N., including the village of Gommecourt, fell into their hands. The enemy had now evidently fallen back into a previously prepared line of defence—the trench system known as the Le Transloy-Loupart line, cutting off the Ancre salient and covering the villages of Le Transloy, Grévillers, Achiet-le-Petit and Bucquoy. It was possible that he would make a stand on this defensive line. If not, undoubtedly his withdrawal would be conducted on a more comprehensive scale altogether and on a wider front.

Owing to the heavy work required to be executed in rendering the roads passable, and moving forward guns, ammunition and supplies, in addition to the necessity for gaining ground to within assaulting distance of this defensive system, a delay of a week occurred before operations of a more serious character could be undertaken. On March 11 and 12 the Le Transloy-Loupart line was subjected to so effective a bombardment that on the morning of the 13th the enemy abandoned this strong position. Grévillers and Loupart wood were immediately occupied, and preparations put in hand to attack the enemy's next line of defence, which covered Bapaume and Achiet-le-Grand.

For some time prior to this date indications had been observed of a further and wider extension of the German withdrawal. It had been ascertained that the Germans were preparing with feverish haste a new and powerful defensive system, the Hindenburg Line, which, branching off from the original defences near Arras, ran S. E. for 12 m. to Quéant and thence passed W. of Cambrai in the direction of St. Quentin. The immediate object appeared to be to escape from the salient between Arras and Le Transloy, but it was also evident from the preparations the Germans were making on a grand scale, that they contemplated an eventual evacuation of the greater salient between Arras and the Aisne valley N.W. of Reims. The withdrawal to the Hindenburg defences would cause a very considerable contraction in the length of the line, with a consequent increase of the German reserves. It was evident that the Somme battles of 1916 had materially reduced his strength, and with the expected onslaughts on the western front, coupled with a Russian offensive on a grand scale, it was necessary for them to contract the front and conserve their strength.

Constant watch had accordingly been kept by the British along the whole front S. of Arras, strong patrols, kept alert and active, pushing forward here and there, with the result that St. Pierre Vast wood was occupied on March 16. Meanwhile information was received which indicated the reduction of the enemy's forces S. of the Somme, and pointed to the probability that his line in that sector was being held by rear-guard detachments supported by machine-guns, whose withdrawal might be expected at any moment.

It was evident that the enemy was withdrawing according to a carefully prepared plan along the entire front of recent operations and on both banks of the river Somme. Orders were accordingly given by the British G.H.Q., in conjunction with the French, for a general advance on the morning of March 17. Except at certain localities where detachments of infantry and machine-guns had been left to cover his retreat, there was little serious resistance to the advance, and that resistance was rapidly overcome.

On March 17 Chaulnes was captured by the 61st Div. and Bapaume by the 2nd Australian Div., while further to the right the French entered Roye. On the following and subsequent days the advance continued, and the whole intricate system of German defences in this area, consisting of many miles of powerful well-wired trenches which had been constructed with immense labour, passed into the hands of the Allies.

On March 18 the British 48th Div. gained the important tactical position of Péronne, and Mont St. Quentin which lies above it. The possession of this locality at the angle of the Somme showed clearly that the enemy would not stand on the line of the river, for it outflanked that line to the south. The bridges over the Somme, which had been systematically destroyed, were temporarily and partially repaired with great rapidity, and the British troops, passing over, deployed into open country with patrols and cavalry thrown forward.

By this time the Allies' advance had reached a stage at which the increasing difficulty of maintaining the communications rendered it imperative to slacken the pace of the movement. Not only had the bridges over the river Somme been destroyed, and the roads rendered almost impassable both artificially and from the weather, but the wide belt of devastated ground over which the Somme battle had been fought offered immense difficulties to the passage of guns and transport. Moreover, in

front lay an enemy whose armies were capable of launching a vigorous counter-offensive. Strong detachments of his infantry and cavalry occupied tactical points along the line of advance, serving to keep the enemy supplied with information and as a screen to his own movements. His guns, which had already been withdrawn to previously prepared positions, were available at any moment to cover and support a sudden counter-stroke, while the conditions of the country across which the Allies were moving made the progress of their own artillery unavoidably slow. The bulk of the enemy's forces were known to be occupying a very formidable defensive system, upon which he could fall back should his counter-stroke fail. On the other hand the Allies, as they moved forward, l ft all prepared defences farther and farther behind them. In such circumstances the necessity for caution was obvious. In order to combat these dangers and difficulties, the Allies were compelled, at the various stages of the advance, to select and put into a state of defence successive lines of resistance, which the main bodies would occupy, and in which they could give battle in the event of a hostile riposte. Meanwhile advanced guards, patrols and reconnoitring detachments pushed ahead and maintained touch with the enemy, and roads, railways, bridges, telegraphs and telephones were constructed or restored with rapidity.

As the Allies approached the Hindenburg Line, the resistance of the enemy stiffened and the fighting for the various tactical localities became more severe. During the first week in April the British had almost reached the Hindenburg Line, and had gained possession of the villages of Lempire, Epehy, Metz-en-Couture, Lagnecourt, Noreuil, Croisilles, Henin-sur-Cojeul and Beurains. The enemy was now withdrawn to his great defensive line, which he had taken months to prepare, shortening his front considerably and enabling him to bring several divisions into reserve. He had in front of him a devastated zone where the mounting of an Allied attack would present extreme difficulties, thereby releasing yet other troops from the guard of the trenches to pass into reserve.

(*G*) Battle of Arras (April–May 1917).—At the close of 1916, and before the appointment of Gen. Nivelle to the command of the French forces, a general plan had been agreed upon by all the Allies to conduct a simultaneous offensive on all fronts. The British part in this offensive was to consist of a double attack along the Scarpe and Ancre valleys, to cut off the Gommecourt salient created as a result of the Somme fighting. The V. Army was to attack along the Ancre, the III. Army was to debouch from Arras along the Scarpe, while the I. Army (Canadian Corps) was to secure the left flank of these operations by seizing the Vimy ridge. Owing to the exhaustion of the French armies the main operations were to be conducted by the British, who would not press the attack unduly in the direction of Cambrai, but be prepared to switch rapidly to the N. and undertake further operations of greater dimensions in Flanders.

The appointment of Gen. Nivelle in Dec. 1916 to the chief command of the French, and the acceptance of his plan of offensive, dislocated the strategical plans for the British armies at this particular juncture.

The Nivelle plan gave the French the major rôle, as indicated earlier, namely, that of delivering a decisive blow from the Aisne front, while the British operations in Artois were to be of a subsidiary character. It is to be noted in this connexion that the extension of the front in relief of the French caused a reduction of power to the British which materially affected their operations throughout the remainder of the year. The Nivelle plan relied on the success of the main offensive by the French, but if that failed the subsequent operations would be seriously handicapped. This was a matter of first-class importance, seeing that the French had already been overstrained while the British were reaching the height of their strength and efficiency. Apart from this, the actual tactical scheme and dispositions required little modification as a result of the acceptance of the Nivelle plan.

General Nivelle did not altogether approve of the plan of the British commander-in-chief, and urged that the attack on the Vimy heights should be abandoned and that the concentration should be effected farther S. on the Arras–Ancre front, pointing out that the inclusion of Vimy would cause too wide an extension and dissipation of force. This point is of some interest as showing the difficulties which a commander has to face in the selection of his front of attack and objectives. Sir Douglas Haig had, however, given the closest attention to the various factors affecting the situation, and refused to give way. His arguments were mainly two: firstly, that the capture of the Vimy ridge was essential to secure the left of his operations, and secondly, that any attack mounted S. of Arras, and S. of the point where the Hindenburg Line hinged on the main German front, would be delivered into a pocket or would be entirely dislocated by a voluntary withdrawal of the enemy from the Gommecourt salient, whereas the German forces were bound to stand and fight for the Vimy ridge. The British commander-in-chief scented the retreat of the Germans to the Hindenburg Line and laid his plans to meet that eventuality. The result was that even after the German retreat little or no alteration was necessary. Had he, however, given way to the pressure placed upon him and mounted his attack from Arras to Gommecourt, the operation, which was required by Gen. Nivelle to draw in the hostile reserves and pave the way for the main French attack on the Aisne, could not have taken place at all.

The task of the British was to attract as large forces of the enemy as possible and so reduce the opposition to the French. As soon as the German retreat developed, all those troops and heavy artillery which were not required with the V. Army in its advance from the Ancre were diverted to the III. and I. Armies in order to strengthen their attacks to the utmost.

The preparations for a great offensive, where reliance is placed on artillery to destroy the enemy's defences and reduce his fire-power to such a point as to enable a successful advance to be made, are extremely long and arduous. When transport requirements on the Arras front were first brought under consideration, the neighbourhood was served by two single lines of railway leading to Arras, the combined capacity of which was less than half the requirements. Considerable constructional work, therefore, both of standard- and narrow-gauge railway, had to be undertaken to meet the programme. Roads had to be improved and adapted; new roads had to be constructed, and material massed forward for construction across the enemy's defences as soon as the troops advanced. For this latter purpose use was made both in this and in later offensives of plank roads. These were built chiefly of heavy beech slabs laid side by side, and were found to be of great utility, being capable of rapid construction over almost any nature of ground. By these means the accumulation of the vast stocks of munitions and stores of all kinds required for the offensive, and their distribution to the troops, were made possible. Hutting and other accommodation for the troops concentrated in the area had to be provided in great quantity; an adequate water-supply had to be guaranteed. Very extensive mining and tunnelling operations were also carried out. In particular, advantage was taken of the existence of a large system of underground quarries and cellars in Arras and its suburbs to provide safe quarters for a great number of troops. Electric light was installed in these caves and cellars, which were linked together by tunnels, and the whole connected by long subways with the trench systems E. of the town.

A problem peculiar to the launching of a great offensive from a town arose from the difficulty of ensuring the punctual debouching of troops and the avoidance of confusion and congestion in the streets both before the assault and during the progress of the battle. This problem was met by the most careful and complete organization of routes.

Practically the labour of the whole of the troops was required to carry through all this work, and while this immense task was proceeding, the British IV. and V. Armies were vigorously pursuing the enemy to the Hindenburg Line, and the French front was in process of being relieved as far S. as the Amiens-Roye road. All this placed a heavy strain on the British troops.

Meanwhile, during the first three months of 1917, negotiations of fundamental importance were proceeding between the high commands and the Governments of France and Great Britain, touching on the principle of unity of command. General Nivelle desired to secure the command of all the forces involved, both British and French. Certain differences of opinion early declared themselves between the British and French commanders-in-chief. These were chiefly in the first instance in connexion with the date of attack, and the extent to which the French troops in front line should be relieved. The transportation service and the Nord railway were not equal to the work of operations on so great a scale at so early a date as that proposed by Nivelle; and in view of the fact that the British commander-in-chief desired to give his troops some rest and training and was somewhat sceptical as to the degree of success which would be attained by the French, was desirous of limiting the extension of his front to the Amiens–Villers Bretonneux road. A temporary agreement on Jan. 1 that the attack should take place as early as possible, and that the French should be relieved as far as the above road by the end of Jan., did not satisfy Gen. Nivelle; the latter referred the whole question to his Government and, indirectly, to the British War Cabinet, with the result that a Cabinet meeting was held in London on Jan. 15 at which both Sir D. Haig and Gen. Nivelle were present. The conclusions arrived at were as follows: (*a*) the British to relieve the French forces as far S. as the Amiens–Roye road, relief to be completed by March 1; (*b*) the offensive to commence on April 1 at latest; (*c*) vigorous exploitation to be undertaken by all the forces both French and British, if necessary. The French troops in front line were accordingly relieved to the Amiens–Roye road, and preparations pushed forward to deliver the attack at the earliest possible date. But the transport difficulties had become so acute that, notwithstanding the fact that every available British soldier was utilized for railway construction and other work, a serious break down in the Nord railway system appeared to be inevitable, and the matter had to be referred to the French Government with a view to obtaining greater facilities. Further negotiations in regard to the problem of command took place secretly between the British and French Governments, and materialized in the Calais conference on Feb. 26 and 27 1917. This conference had originally been summoned to discuss the question of transportation. There were present: M. Briand (premier), Gen. Lyautey (Minister of War), Gen. Nivelle (French C.-in-C.), Mr. Lloyd George (British Prime Minister), Gen. Robertson (C.I.G.S.), Sir D. Haig (British C.-in-C.), Gen. Kiggell (C.G.S.). A scheme was set before the conference by the French Government for the establishment of an Allied G.H.Q. and the appointment of a French generalissimo, and the breaking up of the British divisions to form an "amalgam" with the French troops. General Robertson and Sir D. Haig were in complete ignorance of this proposal until the cut-and-dried scheme was produced; the British Prime Minister, however, while opposing the French proposal to break up the British army and form an "amalgam" with French brigades, directed these two officers to draw up a scheme of command, by which the control of operations in the coming battle would be solely in Gen. Nivelle's hands, and the British army under his orders. This was the decision of the War Cabinet. The scheme was accordingly drawn up in the course of the morning of Tuesday Feb. 27, so that when the conference met at 11:30 A.M. on that day, discussion was limited to questions of detail. Finally the French War Committee and British War Cabinet agreed to the following arrangements:—

(1) The British War Cabinet recognizes that the general direction of the campaign should be in the hands of the French commander-in-chief.

(2) The British commander-in-chief to conform his plans to those of the French during the preparation and progress of the projected campaign.

(3) Within the limits of (2) the British commander-in-chief will be permitted to utilize his own resources and forces in the manner which he considers most desirable.

(4) In regard to (2) an exception will be made in a case where he considers that such action would endanger the safety of the army or prejudice its success; in that case a report shall be made, together with the reasons, for the information of the War Cabinet.

(5) The respective Goveroments will decide the date at which the operations referred to in (1) and (2) shall be deemed to be at an end.

As all students of war agree, within the army of a combatant nation, unity of control is essential to secure the most effective execution of military operations. In theory, it is equally desirable in all circumstances. There is, however, a difficulty inherent in applying the principle of unity of control to Allied nations. This difficulty lies in the incidence of responsibility. For example, if the British armies are placed under the command of a French general, the British commander cannot be held responsible to the nation. The responsibility for the British armies cannot devolve on the French commander, and must therefore devolve on the British Government. At the Calais conference, however, an effort was made by the British War Cabinet to make the field-marshal commanding the British forces retain responsibility by instructing him to conform his preparations to the views of the French commander, except in so far as he considered that this would endanger the safety of the army or prejudice the success of its operations.

The battle of Arras was the first occasion on which the experiment was tried of securing a form of unity of command, and after the conference of Calais the British forces to be engaged in the battle were placed, within the limitations noted above, under the general control of Nivelle. Certain differences of opinion, however, still existed, and the whole question was again referred to the Governments, with the result that the two commanders-in-chief and two Cabinets met in London on March 13 in order to define the position more clearly.

During the month of March, as previously narrated, the Germans continued to withdraw to the already prepared Hindenburg Line, followed up and pressed by British troops, until early in April they were established in positions covering that line. On the British side, the extensive preparations necessary were pushed ahead as quickly as possible and so far as the available transport facilities permitted. The general plan agreed upon was that the British attack should be launched as early as possible in April and that the French main attack on the Aisne should follow two or three days later. This was to permit and induce the German reserves to be drawn into the British battle and towards the British front, and thus enable the main attack by the French to be delivered with greater prospects of success and exploitation. The British actually launched their assault on April 9, but for reasons of unfavourable weather the French postponed their attack until April 16. Prior to the offensive the new German lines of defence on the British front ran in a general north-westerly direction from St. Quentin to the village of Tilloy-les-Mofflaines just S.E. of Arras. Thence the German original trench systems continued northwards across the valley of the Scarpe to the Vimy ridge which, rising to a height of 475 ft., dominates the country eastwards. The front attacked by the III. and I. Armies on the morning of April 9 extended from just N. of the village of Croisilles, S.E. of Arras, to just S. of Givenchy-en-Gohelle at the northern foot of the Vimy ridge, a front of nearly 15 miles. The enemy's defences comprised the normal powerful defensive front consisting of three separate and heavily wired trench systems, and in addition, from 3 to 5 m. further E. a new defensive system, known as the Drocourt–Quéant line, which in fact was a northward extension of the Hindenburg Line, branching from that line at Quéant.

The great strength of these defences demanded very thorough artillery preparation, and this in turn could only be carried out effectively with the aid of the air service. A greater mass of artillery, both guns and howitzers, was used for preparation in proportion to the front engaged than had yet been available in any previous British attack. Three weeks prior to the attack the systematic cutting of the enemy's wire was commenced, while the heavy artillery searched the enemy's back areas and communications. Night firing, wire cutting and bombardment of hostile trenches, strong points and billets continued steadily

and with increasing intensity on the whole battle-front till a few days before the assault when the general bombardment was opened. During this latter period extensive gas discharges were carried out and frequent raids undertaken by day and night along the whole front of attack.

Aircraft were incessantly at work during the whole of this time not only in air fighting and directing the artillery fire, but also in photographing the enemy's defences so as to ascertain the extent of damage effected and the best means of approach for the infantry. Much intelligence and information was gleaned from these photographs as to the progress of the preparation, and from the raids as to the condition of the enemy, and any modifications in regard to his method of holding his defences.

The general object of the attack was to engage and absorb the maximum number of hostile troops; the general plan was to secure the high ground at Monchy-le-Preux and the Vimy ridge and to bring the V. Army into effective operation on the southern flank of the battle; the general method of attack was a succession of comparatively short and deliberate advances, the separate stages of which were arranged to correspond approximately with the enemy's successive trench systems. As each stage was reached a short pause was to take place according to a prepared time-table to enable the troops detailed for the attack on the next objective to form up for the assault.

Tanks were allotted to each corps for specific tasks, such as the capture of the powerful redoubts of Telegraph Hill and the Harp (just S. of Tilloy-les-Mofflaines) and Railway Triangle, a stronghold formed by the junction of the Lens and Douai railway lines E. of Arras. The whole scheme of attack along the entire 15-mile front was carefully coördinated. A special feature in the operation was the debouching of the troops to the assault directly from the town of Arras, the subterranean passages and caves of which had been prepared so as to harbour the reserve troops and enable them to pass protected to the trench systems, and so to the assault.

The troops engaged in the attack were as follows (from S. to N.): III. Army (Gen. Sir E. H. H. Allenby), VII. Corps (21st, 30th, 56th, and 14th Divs.), VI. Corps (3rd, 12th, 15th, and 37th Divs.), XVII. Corps (9th, 4th, 34th, and 51st Divs.), I. Army (Gen. Sir H. S. Horne), Canadian Corps, 1st, 2nd, 3rd, and 4th Canadian Divs., and 13th Bde. (5th British Division). In all there were 17 divisions, with 989 heavy guns and 1,890 field pieces. In addition the Cavalry Corps was brought forward behind the III. Army, in case the development of the battle should give rise to an opportunity for the employment of mounted troops.

The general attack on April 9 was launched at 5:30 A.M. under cover of a heavy and effective artillery barrage; the infantry advanced everywhere, and within 40 minutes the whole of the German first line system had been stormed and captured, except at the northern extremity of the Vimy ridge. At 7:30 A.M. the advance was resumed according to programme; more severe fighting took place in view of the greater opposition encountered. Several strong points and localities were stubbornly held by the enemy, but by 12 noon the whole of these and all the second objectives with the exception of the railway triangle had fallen, from Neuville Vitasse as far N. as La Folie farm. As always happens in such a battle, the enemy's troops managed to retain certain tactical localities. Meanwhile the artillery was brought forward to support the attack on the third objectives. Owing to the long range the wire in front of the enemy's third trench system had not been effectively cut in many places; nevertheless good progress was made, and many batteries were captured.

The battle now inevitably became more ragged, owing to the increasing opposition and to the local modification of plans necessitated by the unexpected occurrences inseparable from the battlefield. South of the Scarpe, St. Martin and Feuchy Chapel on the Arras–Cambrai road were captured. In the Scarpe valley the 15th Scottish Div. after a long struggle stormed the railway triangle, and moving rapidly forward captured the village of Feuchy. The 37th Div., hitherto in reserve, whose rôle it was to pass through the first-line troops to the assault of the high ground and village of Monchy-le-Preux, endeavoured to widen the breach made in the enemy's third line of defence in order to carry out its task, but was held up by the wire. South of the Scarpe, the enemy's third line had been captured in places, but he still retained possession of the greater portion of it, together with the high ground of Orange Hill and Monchy-le-Preux. North of the Scarpe practically the whole of the day's programme was carried through. On the right the 4th Div. in reserve passed through the troops in front line, and according to plan captured the village of Fampoux, thus making a great breach in the enemy's third system of defence. In the centre the Canadian Corps stormed the Vimy heights, entrenched itself on the eastern slopes, and sent patrols out along the front. On the left the 4th Canadian Div., encountering violent opposition at Hill 145 on the northern extremity of the ridge, was compelled to postpone the attack till the following day.

The operations of April 9 had been eminently successful, in spite of heavy squalls of snow and rain; and large numbers of the enemy's troops and guns had been captured.

During the night of the 9th to 10th the 37th Div. made progress through the break in the German third line S. of the Scarpe, advancing to the northern slopes of Orange Hill; and on the morning of the 10th about noon the advance became general, the whole of the enemy's third line S. of the Scarpe being reduced, and the 37th Div. reached the north-western edge of Monchy-le-Preux. A great struggle then centred round this village, and all efforts of the infantry to seize it directly, and of the cavalry to pass around either flank of it, failed, chiefly owing to the lack of effective artillery support due to the long range and the rapidity of the advance. On the morning of the 11th, however, assisted by tanks, the fight was resumed, and by 9 A.M. the village was captured, and subsequently many counter-attacks repulsed.

Meanwhile the Germans had been stubbornly defending the Cojeul valley and the Hindenburg defences at their junction with the old third line, a vital part of the front, where the open forward slopes, swept from end to end by the enemy's machine-guns, rendered any advance extremely difficult. In this area an operation of a bold and hazardous character was undertaken on the morning of the 11th, which was nearly successful. At 4:30 A.M., in conjunction with an attack by the right of the III. Army on Hemnil and Wancourt, the V. Army (4th Australian and 62nd Div.), assisted by tanks, made a gallant effort to breach the Hindenburg Line in the neighbourhood of Bullecourt. The execution of the attack, being over a wide extent of open country, was exceedingly difficult; Australian troops, however, penetrated as far as Riencourt-lez-Cagnicourt and the 62nd Div. reached Bullecourt, but owing to determined opposition and the failure of the attacks by the right of the III. Army these positions could not be maintained. Had both attacks been successful and the two armies joined hands forward, a very wide breach in the enemy's defences in an important area of the battlefield would have been effected with far-reaching results. It was not till the morning of April 12 that the 21st and 56th Divs. succeeded in capturing Hemnil and Wancourt.

North of the Scarpe much fighting of an indeterminate nature took place at Roeux and the neighbourhood on this day, but at the extreme northern extremity of the battlefield the 4th Canadian Div. and 24th Div. secured the whole of the important positions on the flank of the Vimy ridge and astride the Souchez river at the "Pimple" and "Bois en hache." The Germans now began to withdraw from the eastern slopes of the Vimy ridge, and British and Canadian patrols moved forward until by the evening of April 14 a line had been reached N. of the river Scarpe from Roeux to E. of Bailleul-Hirondelle Wood and Liévin to the old front line at the Double Crassier.

On the right by the evening of the 14th the attacking troops had fought their way forward with great difficulty along the Hindenburg Line as far as Fontaine-les-Croisilles and Wancourt Tower, while farther N. many counter-attacks on Monchy-le-Preux were repulsed.

The main offensive by the III. and V. Armies terminated on the 14th; the artillery support was becoming inadequate, and the troops in front line required relief. A remarkable success had been gained; the British front line had been moved forward some 4 m., and some 13,000 prisoners and 200 guns had been captured. It was not possible, however, to break off the battle, seeing that the French offensive was on the point of being launched, and it was important that the full pressure of the British operations should be maintained in order to assist it. Much had already been accomplished; the enemy had been compelled to pour men and guns into the breach, and a large hostile concentration in the battlefield was in process of being effected.

The only offensive action taken by the Germans during this period in this area occurred on April 15, when they attacked the British position from Hermies to Noreuil with 16 battalions. An initial success, in which some of the British battery positions were overrun, was at once neutralized by a counterstroke which restored the line.

On April 16 the French launched their main offensive on the Aisne. The decisive results which had been looked for were not achieved; there was no rapid break through or exploitation by a reserve army of manœuvre. On the contrary, ragged fighting took place which continued until May 5, and the French armies, worn out by more than two years of heavy fighting, were in no condition to sustain an exhausting offensive. The unified command was in the hands of a French general who had planned and conducted operations which proved to be unsuccessful. From April 15 to May 5 the British continued their operations on the Arras–Vimy front at the request of the French and in order to carry out the rôle of absorbing the enemy's reserves. During this period attacks were executed by the British on April 23 and 28 and on May 3 and 5, with the result that the line was pushed forward to include Quemappe-Gavrelle and Arleux, and some 6,000 additional prisoners and 50 guns were taken. On May 5 the great offensive operations on the Aisne and Scarpe were brought to a close, and on May 15 Gen. Nivelle was relieved of his command. This brought to naught the effort to obtain unity of command, and the operations provided a warning as to the dangers involved where armies of different nationalities are concerned.

Such was the story of a great and successful British effort under conditions of abnormal difficulty. The Russian Revolution had declared itself, the French armies had broken down, the enemy was recovering his reserve power, and the period of the year was getting late for the transference of operations elsewhere. The British field-marshal commander-in-chief then decided immediately that it was necessary to continue on the offensive and to transfer the theatre of operations to the north.

(*H*) The Relief Offensive in Front of Lens.—The great British offensive in Flanders was launched on July 31 1917 and continued to be pressed throughout the autumn. Towards the middle of Aug. a slight improvement took place in the weather, and advantage was taken of this to deliver the second attack E. of Ypres. As it was desirable to prevent the enemy from weakening the remainder of the front so as to effect a greater concentration in Flanders, it was desirable and even necessary to threaten and undertake operations of a minor character at various points to pin the enemy's reserves. A highly successful operation was carried out in the neighbourhood of Lens, and the threat to this town undoubtedly had the effect of preventing the enemy from concentrating the whole of his attention and resources on the main battle-front.

At 4:25 A.M. on Aug. 15 the 1st and 2nd Canadian Divs. attacked on a front of 4,000 yd. S.E. and E. of Loos. The objectives consisted of the strongly fortified Hill 70, which had been reached, but not held, in the battle of Loos in Sept. 1915, and the mining suburbs of Cité Ste. Elisabeth, Cité St. Emile, and Cité St. Laurent together with Bois Rasé and half Bois Hugo. The observation from Hill 70 had been very useful to the enemy, and in the possession of the British, would materially increase their command over the defences of Lens. Practically the whole of these objectives were gained rapidly at light cost, and in exact accordance with plan. Only at the farthest limit of the advance a short length of German trench W. of Cité St. Auguste resisted the first assault. This position was again attacked on the afternoon of the following day and captured after a fierce struggle lasting far into the night. A number of local counter-attacks on the morning of Aug. 15 were repulsed, and in the evening a powerful attack delivered across the open by a German reserve division was broken up with heavy loss. In addition to the enemy's other casualties, 1,120 from three German divisions were captured by the British. Thus not only was the British position improved but three German divisions, which might have been used in *roulement* on the Flanders front, were severely handled, and the enemy received a lesson which would prevent him from unduly weakening the defensive fronts.

(*I*) The Battle of Cambrai (Nov.–Dec., 1917).—The repeated attacks delivered by the British in Flanders over a period of more than three months had brought about a large concentration of the enemy's forces in that area, with a consequent reduction of his strength and garrisons in other sectors of his front. The British object in the operations at Cambrai, which took place on Nov. 20 1917, was to gain a local success by a surprise attack at a point where the enemy did not expect it, and on a front which had already been weakened, and thus disarrange the enemy's plans of withdrawing troops from France to operate in Italy. The sector opposite Cambrai had been carefully selected as the most suitable. The ground there was, on the whole, favourable for the employment of tanks which were to play an important part in the enterprise. If, after breaking through the German defence systems on this front, the high ground at Bourlon could be secured and a defensive flank established facing E., and opportunity should be created of exploiting the situation towards the N.W., the capture of Cambrai itself was subsidiary.

As a result of the pressure in Flanders and the Russian Revolution, large German forces had already been brought from the Russian front, partly in exchange for exhausted divisions and partly as additional reinforcements. Moreover, it was certain that heavy German reinforcements would continue to be railed to the western front during the winter. These troops would be largely utilized to strengthen the weakened sector, and if the opportunity, which existed, to deliver a surprise attack at an early date under favourable conditions were not taken advantage of, it would certainly lapse. Against this argument in favour of immediate action must be weighed the fact that the conditions of the Flanders struggle had severely taxed the strength of the British forces, and that the losses, which had not yet been made good, had been heavy.

On the other hand the resources required for the operation were not great, seeing that the force to be employed must be small, for, owing to the requirements of surprise and secrecy, any considerable concentration of troops would be impossible to maintain. The success of the enemy's operations in Italy, too, added force to the arguments in favour of undertaking the operation; although the means available had been reduced by the despatch of troops to the Italian front, the situation on that front was critical, the Italians having been driven back between Oct. 24 and Nov. 10 from the Isonzo to the Piave.

After consideration of these factors, it was decided, by the British command, to undertake the operation, and the execution was entrusted to the III. Army. The general plan of attack was to dispense with previous artillery preparation, and to depend on tanks, of which there would be nearly 500 available, to break down the enemy's wire and cover the infantry advance. No previous abnormal artillery fire was to take place and no registration of guns or any action which might indicate to the enemy that an attack was impending. The infantry was specially trained to work in combination with tanks, and the whole operation depended for success on secrecy and on bold, determined and rapid action.

The German defences on the selected front between Vendhuille on the Scheldt canal and the river Sensée comprised the three

systems constituting the Hindenburg Line (greatly improved during the course of the year) with fortified posts in advance, such for example as La Vacquerie and the north-eastern corner of Havrincourt Wood. Behind this again were two other defensive lines known as the Hindenburg Reserve Line and the Beaurevoir–Masnières Line. That portion of this front which lies between the Scheldt canal and the Canal du Nord offered an opportunity for a tank drive to the N. which would include the capture of the important position about Bourlon. The full force of tanks together with five divisions (12th, 20th, 6th, 51st, 62nd) and a portion of another (36th) were allotted to this front extending from Gonnelieu on the right to Havrincourt Wood on the left. Two divisions were, moreover, to be held in reserve behind this front ready to move forward, and the cavalry was to be at hand ready to exploit a success towards the N. and turn the enemy's defences from the rear. In order to make the front of attack more imposing, to deceive and hold the enemy, gas and smoke attacks, dummy attacks with dummy tanks, artillery fire, raids and subsidiary attacks were to be carried out on an extensive scale both on southern and northern flanks.

All preparations were carried out with the greatest secrecy, and during the evening prior to the battle troops and tanks were moved forward into positions of assembly, great care being taken to muffle the noise to the utmost. This was rendered particularly difficult owing to the hard and frosty weather. Each tank was provided with a compressed brushwood fascine some 8 ft. in depth, for the purpose of assisting it in crossing the main Hindenburg trench, which was of abnormal dimensions.

At 6:20 A.M. on the morning of Nov. 20 1917 the tanks and troops moved forward to the attack on a front of about 6 m. from E. of Gonnelieu to the Canal du Nord opposite Hermies. At the same hour the subsidiary and feint attacks took place. On the principal front of attack the tanks rolled on, protected by a smoke barrage from the enemy's artillery. The Hindenburg Line was rapidly overrun. The 12th Div. after severe fighting at Lateau Wood captured the Bonavis spur. The 20th Div. captured La Vacquerie and stormed Welsh ridge, while the 6th Div. entered Ribecourt. The surprise was complete, and the enemy surrendered in considerable numbers. The 29th Div. which had been in reserve moved forward and, passing through the 6th and 20th Divs., entered Masnières and captured Marcoing and Neuf Wood, securing the passages of the canal at both villages and the bridge intact at the latter. In this neighbourhood it was not possible to enlarge the footing gained on the E. bank of the canal, owing to the arrival of hostile reinforcements in the neighbourhood of Rumilly where severe fighting took place.

Meanwhile the 62nd and 51st Divs. attacked the Flesquières ridge, the latter being stubbornly opposed and seriously delayed by the defence of that place. The 62nd Div. however pressed forward and captured Graincourt, its advanced troops entering Anneux. Flesquières continued to hold out throughout the day against the 51st Div., but troops of the 6th Div. entered Noyelles before nightfall. But for the delay at Flesquières and the destruction of the bridge at Masnières the operations would have been completely successful, and would have opened up a great field for exploitation on the following day.

On the morning of the 21st the attack was resumed. But little progress was made on the Masnières–Rumilly front. Farther W. the village of Flesquières, turned from the N., fell at 8 A.M., and the 51st and 62nd Divs. with tanks and cavalry moving rapidly forward captured Cantaing and Fontaine-Notre-Dame, and reached the southern edge of Bourlon Wood. Throughout the day infantry and cavalry were heavily engaged at Noyelles. On the extreme left the 36th Div. cleared the Hindenburg Line as far N. as Moeuvres.

By the evening of the 21st the British had gained possession of the Bonavis spur, a bridgehead E. of the Canal de l'Escaut including Masnières and Noyelles, the whole of the Flesquières ridge and the ground to the N. as far as the southern edge of Bourlon Wood including Cantaing and Fontaine-Notre-Dame.

It was now nearly 48 hours after the commencement of the attack, and hostile reinforcements might be expected; at the same time it was necessary from the lie of the ground to decide whether to go on and attack the heights of Bourlon or to withdraw to the Flesquières ridge. Owing to the importance of the possession of the Bourlon heights and the visible signs of withdrawal of the enemy, having regard also to the situation in Italy, it was decided to proceed with the attack.

On the 22nd, while the British were carrying out reliefs with a view to the prosecution of the attack, the enemy recaptured Fontaine. On the 23rd the 40th Div. with tanks attacked and captured the whole of Bourlon Wood, but the attempts to secure Bourlon and Fontaine, after a severe struggle, failed.

The struggle for Bourlon resulted in several days of fierce fighting. On the morning of the 24th the Germans counter-attacked and were repulsed; in the afternoon the British attacked, captured the village and beat off a counter-attack, but the resistance on the Fontaine–Bourlon–Moeuvres front was very considerable. On the 25th and 26th the enemy again counter-attacked in force and succeeded in recapturing Bourlon and the wooded spur between that place and Fontaine. The situation in the wood was now somewhat difficult; on the 27th an organized British attack succeeded in improving the position in the wood, but the troops which at one time had entered Bourlon and Fontaine were obliged to fall back again.

During the 28th and 29th no attacks took place, the troops which had been heavily engaged were relieved, and on the whole front efforts were made to strengthen the position gained. During the ten days' fighting 10,500 prisoners and 142 guns were taken, but the main objective, the Bourlon locality, which would turn the whole of the enemy's positions S. of the Sensée canal and river Scarpe, had not been secured. This was primarily due to the initial failure at Flesquières village.

In the last days of Nov. signs were not lacking on the whole of the front between Vendhuille and Bourlon that the Germans intended to regain the positions which they had lost. On the whole of this front they had carried out artillery registration, but the importance of Bourlon to them and the massing of their troops indicated that their main attack would be delivered on the Bourlon front.

Measures were taken accordingly by the British command; this front was strengthened, while five divisions were disposed on the right flank from Cantaing to the Bauteux ravine. Farther S. the original front was held as before, the frontage being wide for the number of troops available. The Guards were in reserve about Villers Guislan, the 62nd Div. on the Bapaume–Cambrai road and the 61st Div. assembling in rear, while four cavalry divisions were available in the neighbourhood. Practically all these troops had already been heavily engaged. All troops were warned to expect an attack.

On Nov. 30 the Germans attacked about 8 A.M., delivering their main assault, as anticipated, on the Bourlon front, and a subsidiary attack on the Cantaing–Vendhuille front. The former was successfully repulsed after the most severe fighting but on the Bonavis spur and in the direction of Villers Guislan the Germans made rapid progress. On this latter front their attack was in the nature of a surprise assault, without any previous bombardment, but accompanied by a hail of gas and smoke shells and bombs. Villers Guislan, Bonavis, Gonnelieu and Gouzeaucourt rapidly fell into their hands, but their advance was stayed by the resolute action of the Guards, assisted by tanks, which resulted in the recapture of Gouzeaucourt and part of the ridge between that place and Gonnelieu, while the troops holding La Vacquerie succeeded in keeping their opponents at bay. Meanwhile on the N., from Fontaine to Moeuvres, the enemy's main assault, delivered between 9 and 10 A.M., and preceded by a heavy bombardment, was repulsed with heavy losses and at close quarters. This assault was repeated during the morning and afternoon, but all attempts of the Germans to gain any important success either on this front or about Masnières failed completely. On the following days, Dec. 1, 2 and 3, there was severe fighting in the open in the

Gonnelieu neighbourhood, with the result that the Germans progressed in the direction of Villers Plouich, capturing the hamlet of La Vacquerie and thus rendering the position of the British troops defending Masnières and Marcoing extremely precarious. Further fighting continued during the next few days, but the Germans' strength was exhausted and their losses had been severe.

It now became necessary for the British command to decide whether to embark on another offensive battle on a large scale, or to withdraw to a more compact line on the Flesquières ridge. Although this decision involved giving up important positions won with great gallantry, withdrawal was undoubtedly the correct course under the conditions. Accordingly on the night of Dec. 4–5 the evacuation of the positions N. of the Flesquières ridge was commenced, and on the morning of the 7th the withdrawal was completed successfully without interference from the enemy. Captured guns and material which could not be removed were destroyed.

The new line taken up corresponded roughly with the old Hindenburg Line from N.E. of La Vacquerie, N. of Ribecourt and Flesquières to the Canal du Nord 1½ m. N. of Havrincourt, *i.e.* about 2 to 2½ m. in front of the line held on Nov. 20 at the commencement of the operations.

These operations undoubtedly had a direct influence on the Italian campaign, by diverting reinforcements and suspending operations at a critical moment when the Allies were making their first stand on the line of the river Piave.

In the offensive it had been hoped by a powerful tank attack and surprise to break and turn the enemy's defences where he was least prepared, and thus created a favourable tactical situation which would place him at a great disadvantage. The failure to secure immediately the Bourlon locality was responsible for the inability to create such a situation, and this was due to the accident at Flesquières, where one German officer handling a field gun put a number of the attacking tanks out of action by direct hits. Success had been very nearly complete.

During the whole of these operations the French were prepared to coöperate with a special force which had heen hrought forward in readiness, should an opportunity have occurred for exploitation. These troops, with the exception of a few guns which were utilized for defensive purposes subsequent to the German counter-offensive, were not brought into action and were eventually withdrawn.

These operations in the neighbourhood of Cambrai should he regarded as an incident in the great four and a half years' battle—a surprise stroke followed by a rapid counterstroke—in which although the British did not achieve their tactical object, the balance of advantage remained to a large extent in their hands. The Germans, though successful in their counter-offensive, were apparently not so successful as they had hoped to be.

The main objects of the attack had been attained. The initiative was retained and the enemy's plans deranged. German reinforcements were prevented from being despatched to the Italian front. The enemy had also been prevented from delivering an attack on the French front, which would undoubtedly have produced disastrous results. (J. H. D.)

ARTS AND CRAFTS (*see* 2.700).—As the "Arts and Crafts" movement grew out of impulses deeper than were, perhaps, apparent in its first artistic issues, it has continued to react in other directions. In the domain of general education its enlivening influence has helped to insure the full recognition of handwork, an educational medium that was in some quarters tending to lapse into a mechanical exercise, as a most fruitful means of artistic expression. This most important development was a reflection of the art workers' direct efforts in education, which aimed at a complete reorganization of the technical and artistic training of young artisans on lines that were, in effect, a revival, so far as was compatible with modern conditions, of the ancient, well tried system of master-craftsman and apprentice. Although not actually the first to put these principles into practice the Technical Education Board of the L.C.C. (whose functions are now absorbed by the London Education Committee) was the first public body in England to establish a school solely for this purpose. The Central School of Arts and Crafts, opened by the L.C.C. in 1896, at first under the joint direction of Sir George Frampton and Prof. W. R. Lethaby, afterwards under the latter alone, began the combined teaching of designing and making, of craftsmanship in the fullest sense of the word, in workshops specially equipped for the production of finished work of the finest type. The methods originated in the Central School were soon adopted in other places; new schools and classes rapidly sprang up in London and elsewhere, and students from the colonies, from almost every European country, from the United States and Japan, carried its influence abroad. In 1900, when the Board of Education reorganized the training of teachers for State-aided schools of art, the courses for the diplomas in design and handicrafts at the Royal College of Art, South Kensington, had been taken over, in addition to his other responsibilities, by Prof. W. R. Lethaby. The students of the college, now trained in the practice of various crafts, have, as principals or teachers of provincial schools, infused a new spirit into the study of design wherever they have gone. In the field of art education the genius, knowledge and enthusiasm of Prof. W. R. Lethaby, follower of Morris, and one of the most prominent figures in the arts and crafts movement, have been factors of far-reaching influence.

Organization.—Although the activities of craftsmen were necessarily restricted, or diverted into unusual channels, during the greater part of the ten years from 1910–20, the period as a whole showed progress in many directions. Local organizations held exhibitions in most of the great cities of the United Kingdom and Ireland, and in many smaller centres. These, together with the steady growth of groups of workers associated together in the practice of some particular craft, or crafts, and the ever-increasing number of skilled individuals, greatly multiplied facilities for the exhibition, sale and purchase of attractive, serviceable goods. Much new work came to the Arts and Crafts Exhibition Society, the parent body, whose periodic shows fulfil a useful purpose in maintaining a high standard of current effort—their main object. The exhibitions of the Home Arts and Industries Association, an amateur forerunner of the arts and crafts movement, whose voluntary workers organize classes in village crafts; of the Women's Guild of Arts; and those of the more recently established National Federation of Women's Institutes, amongst others, have done useful work within their various, more restricted spheres of action.

The tenth exhibition of the Arts and Crafts Society, held in the New Grosvenor Gallery in 1912, continued in the form made familiar in previous years, gathering together into convenient focus a varied assortment of the best achievement of the day. This in some measure prepared the way for a new and important departure. In 1913 the then recently established Exhibitions Branch of the Board of Trade included arts and crafts in the British section of a foreign international exhibition for the first time. The section organized by the Board at Ghent may be said to have recognized the value of the movement as a national asset, and to have introduced officially work of the kind usually seen in London to a European public. Here an attempt was made to unite the various exhibits into a concerted scheme, and to place different groups of crafts in definite relationship to each other. A temporary building, of striking design, the work of Henry Wilson, the distinguished architect and metal worker, contained part of the exhibits. These changes showed the way to new methods of arrangement, and a more interesting form of setting, which were developed still further in future exhibitions. So great was the success of this venture that in the following year a great part of the collection, the best and most extensive that had yet been brought together, was, on the invitation of the directors of the Louvre, transferred to Paris. The special exhibition of British arts and crafts opened by the Board of Trade in the spring of 1914, in the Pavillon de Marsan of the Palais de Louvre, the home of the Musée

des Arts Décoratifs, was a second edition of the Ghent display, set out in a way that added much to its interest and value. Historic masterpieces of the great pioneers of the 19th century, fine examples from former London exhibitions, and new work that had not previously been shown combined to give a review of the growth of the British arts and crafts movement that was of unparalleled interest. The architectural setting, again due to Henry Wilson, adapted the magnificent galleries to their new purpose with complete success. The attainments of British craftsmen, the directness and novelty of their designs and the quality of their workmanship, shown to a public that had not yet seen any considerable collection of British work of this kind, gained enthusiastic appreciation. In Aug. 1914 the exhibition was hurriedly dismantled, and, as it was impossible to return the exhibits to England, the collection remained buried in the cellars of the Louvre until the end of the World War.

In the autumn of 1916 the Arts and Crafts Society held an exhibition at Burlington House by the courtesy of the Royal Academy, and this helpful interest brought the two bodies together most happily for the first time. A room devoted to a small but representative assemblage of earlier work continued an inspiring feature of the Ghent and Paris shows, including much, now in private hands, that, although well enough known in certain circles, had not been seen by a younger generation. These examples included some of the varied productions of Walter Crane (1845–1915), the first president of the Society, and of William Morris, D. G. Rossetti, Ford Madox Brown, Edward Burne-Jones, and others of the same school, and bore witness to the remarkably versatile genius of those times. Innovations in the arrangement of the exhibits, inherited from the European ventures, and daring developments of the decorative setting of the exhibition that displayed the enterprise of the designer, the new president, Henry Wilson, and the skill of the constructor, Francis W. Throup, brought an unwonted liveliness into the Academic precincts. A series of large paintings in temporary architectural surroundings completely masked the walls of several galleries. Conspicuous in this practical expression of the revived interest in mural decoration were adventures in work of unusual scale by Augustus John, William Rothenstein, Charles Sims, George Clausen and Maurice Greiffenhagen, to mention but a few of the many well-known painters who took part in the most imposing experiment of the kind yet attempted. A series of rooms were erected, decorated and completely furnished by groups of craftsmen, and appropriate collections were brought together in illustration of "University," "Ecclesiastic" and other types of work. A particularly encouraging feature was the number and quality of exhibits by young workers, for the most part students in schools of arts and crafts. Groups of students working under the direction of their masters also took part in the decoration of the galleries, a new departure in collective education that should bear good fruit in the future.

Relation to Industries.—In this exhibition a room was set apart for a small display of articles of everyday use of a kind hitherto unrepresented in the Society's shows, arranged by the Design and Industries Association, a body that had been recently formed to better the quality and fitness of goods on sale to the general public through the usual channels of supply. This Association pays but little regard to the long-standing feud between handwork on the one side, and machine and scientific production on the other, but aims at securing an increased output and sale of all kinds of products of the best possible quality. By means of its well produced publications, able lectures, and instructive exhibitions the Association has gained considerable influence all over the United Kingdom, and has succeeded in banding together in close coöperation a number of designers, craftsmen, manufacturers and distributors. It was becoming more and more apparent that continental manufacturers were gaining great advantage from the ideas of British designers—indeed in some cases more than were the British themselves. The British manufacturer and designer had come to regard each other with a certain amount of suspicion; the one had no use for the "long-haired artist," who in his turn mistrusted the standards of design of the other. Foreign observers, especially in Germany, were taking deep interest in the British arts and crafts movement, and reaping very practical results from the knowledge they had gained. So thoroughly were these investigations being carried out that at least one German university had established a professorial chair for the special study of the economics of arts and crafts. Foreign goods that embodied the designs and ideas of British craftsmen were securing an ever widening market, not only abroad, but also in England. As a case in point the history of English influence on German printing is interesting. Several German type founders cut "punches" based on the calligraphy of Edward Johnston and sold "strikes" (*i.e.* matrices) to English letter founders, who gave the type English names in blissful ignorance that the designs were of English origin. The Design and Industries Association deals with the whole question of production and distribution and endeavours to bring together all concerned in an attempt to attain high standards of work and to promote their common interests. Its small exhibit at the Royal Academy, which illustrated a new point of view in artistic design and manufacture, aroused an interest which has been maintained by other exhibitions of the same character. Another "side show" included pottery, printed fabrics and other things made at the Omega workshops. This small selection of the work of Roger F. Fry gave an illustration of his very novel designs, and was a piquant demonstration of the catholicism of the selection committee of the Society.

Encouraged by its success in introducing the products of British craftsmanship to foreign buyers, the Board of Trade determined to extend its efforts so as to include all possible markets, at home as well as abroad. In conjunction with the Board of Education it founded, in 1920, the British Institute of Industrial Art, with Sir Hubert Llewellyn Smith as chairman. One of the chief means by which this new body proposed to further its objects was the establishment in London of a current exhibition of modern British work, representative of a high standard of quality, and of the latest developments in industrial art. It also undertook the organization in the provinces and abroad, of special temporary and travelling exhibitions of the same character, either independently or in coöperation with the Board of Trade, or other bodies. In addition to these activities it has established a bureau of information on all questions relating to industrial art and to British and foreign markets. It proposed to establish a purchase fund with the object of securing for the State selected modern work of outstanding merit. All work intended for exhibition comes before a selection committee, of which one section is devoted to manufactures, *i.e.* multiple production by hand or machine, and another to the work of individual craftsmen. A number of experts in the various matters that form the business of the Institute were elected fellows, and several exhibitions were held at the galleries of the Institute in London.

This brief summary of the chief recent developments in the organization of craftsmen shows an extension of the scope of the arts and crafts movement far beyond that accepted by the original workers. It is perhaps doubtful whether the pioneers of the last century, with their instinctive mistrust of machinery and commercial production, would have welcomed all these modern innovations with enthusiasm. But however commercial the tendencies of "industrial art" may appear, they have been brought about by the inevitable force of economic responsibilities—responsibilities that are in a measure the heritage of success. The new organizations are broad and elastic; they necessarily included all sincere workers who set themselves high ideals of design and workmanship. The labours of these are, indeed, the basis of their operations, which tend, not to supplant handwork or eliminate the artist, but to widen his sphere of action by giving him his proper place in the control of machine-made things.

Calligraphy and Illumination.—The present renaissance of writing is due entirely to the perfectly equipped efforts of Edward Johnston, who, in the latter years of the last century, took up with rare persistence the study of the materials and methods of the great scribes of the past, and produced a number of MSS. written in a hand based on traditional usage, but quite suited to modern needs. As a teacher he gathered around him a band of students, of whom several specialized in writing, and as calligraphists, and, in their turn, teachers, spread his methods far and wide. From this beginning arose the remarkable revival of fine formal writing, inscriptions, and lettering that is one of the most interesting signs of the times. Since 1910, Johnston's work has been frequently exhibited in many places; he stands without rival as a really great scribe. His MSS., addresses, and inscriptions, decorated with initials and ornaments in gold and colour, are highly prized. Graily Hewitt, a distinguished pupil of Johnston's, follows closely in his footsteps with work that is widely appreciated. He is also a teacher of authority and has given attention to the training of children, for whose instruction he has written some attractive copybooks. H. Lawrence Christie is a calligraphist whose inscriptions and MSS. show fine style, and A. E. R. Gill is the most distinguished figure in the long-neglected field of lapidary inscriptions. In the illumination of MSS. and printed books no finer work has been done in recent times than that of Mrs. Sydney Cockerell. Her designs show a vivid poetic imagination; they are, quite modern in character, absolutely without trace of the archaic mannerisms that many workers in this art affect. Exquisite in drawing and colour, her decorations unite harmoniously, not only with the written or printed page, but also with the spirit of the author whose work she decorates. Mrs. Louise Lessore Powell has enriched a number of MSS. with great delicacy and charm. The accomplished illuminations of Allan F. Vigers, based on a most

watchful study of birds and flowers, have a delightful brightness of colour and design. His ornaments for the Cape Town memorial of the South African War, written by Graily Hewitt, were interesting examples of his work in another vein.

Printing.—During the earlier years of the century book production made remarkable advances. The books issued by the Doves Press, founded in 1900 by T. J. Cobden-Sanderson and Emery Walker, were rapidly taking a place as the sole possible rivals of the classic products of the Kelmscott Press, to the excellence of which the expert knowledge of Emery Walker had paid its contribution. The Ashendene Press books, printed by C. H. St. John Hornby, and those of Charles Ricketts's Vale Press, were also increasing the reputation of British printing. In the trade generally a new activity was apparent; fine examples of books, and type of good design were closely studied by publishers and others, who had formerly paid but little attention to matters of this kind. The best British work gained the highest esteem wherever good printing found favour. In Germany, books based upon British models, or even produced under the supervision of authorities such as Emery Walker and Douglas Cockerell, showed how the genius of British printers and binders was growing in foreign appreciation. No trade, however, felt more severely the stress of the years of war; no new press of outstanding merit arose to range its products with the earlier triumphs of the century. An edition of the *Odyssey* was issued by the Oxford University Press, printed in the Greek type designed by Robert Proctor (1868–1903); and a new fount, designed by Herbert P. Horne (b. 1864), was used by the Riccardi Press. The old-established Chiswick Press maintained, under Charles T. Jacobi, the reputation that earned for it a worthy place in the revival of fine book work. Technical education in book production was developed in a special department of the Central School of Arts and Crafts under the supervision of the leading members of the trade. Under the instruction of J. H. Mason, an authority on printing, and of a binder, Peter McLeish, the students produced books of quite extraordinary merit, and gained in a few years a very complete introduction to the whole field of book production, passing on, after specializing for a period as either printers or binders, into printing offices and workshops with a foundation of craftsmanship and design of most satisfactory breadth.

Bookbinding.—An ever-increasing number of well-bound books, plainly or elaborately finished, bore witness to the improved taste and high standard of craftsmanship to which bookbinding had been brought. In Paris were shown some of the rarely exhibited volumes of T. J. Cobden-Sanderson, the first of the modern binders to bring back into use so much of the tradition of sound workmanship that was giving place to untrustworthy expedients. Practical qualities resulting from good craftsmanship, combined with brilliant richness of design, made all his books specially remarkable. His pupil, Douglas Cockerell, exhibited much admirable work, with decoration of distinction. As a teacher he had, perhaps, more direct influence upon the bookbinding trade than any other worker. Sound methods fortified by much original research into the qualities of materials were, through his teaching, handed on to many skilful pupils, amongst whom may be named F. Sangorski (1875–1912) and his partner G. Sutcliffe, and Charles McLeish, the younger, who inherited much of his father's skill. Cockerell's careful study of "library" binding, suitable for everyday use, was specially serviceable to collectors of books. In the conservative restoration of ancient books his patient craftsmanship and wide experience gave a new lease of life to many priceless volumes in public and private libraries. Queen Mary lent for exhibition in Paris a beautifully bound copy of the reproduction of the *Psalter of Queen Mary Tudor* printed by C. H. St. John Hornby at the Ashendene Press. This binding, designed and executed by Katharine Adams, together with others from the same hand, showed the delicate tooling and clear, restrained designs of this gifted worker, who takes a unique place amongst modern binders. A further selection of her work, including a magnificent volume lent by King George, was shown at the Royal Academy in 1916.

Furniture.—The almost universal tendency in cabinet-making towards the reproduction of antique models implies a certain regard for traditional forms, but gravely obstructs the development of furniture really suited to present day needs. Overpowered by the craze for "old things," modern designers but seldom attempted to meet practical requirements in a straightforward, logical spirit. The absurdities of Tudor bathrooms, or Adams' kitchen ranges, would not be tolerated nowadays; but, whilst up-to-date domestic engineering is admitted into historic mansions as a matter of course, "period" furniture is still thought fitting for houses of frankly modern design. Some few makers have built up reputations with work of utility and originality. The death of Ernest W. Gimson (1864–1919) removed the most distinguished cabinet-maker of the time. His work of all kinds, and he was a master of many arts, had a pleasant English stamp, and was always his own beautiful solution of some practical problem of use or comfort. No work more soundly made, or directly designed, than his has been produced; wherever it went it raised new standards of taste. Cabinets designed by Prof. W. R. Lethaby, now too rarely seen, had the distinction that marks all his work. Sidney and Ernest Barnsley produced attractive furniture of practical design and sound make. Charles Spooner, and A. Romney Green, whose cabinet work was often exhibited, were both interesting designers and makers whose work showed individuality and charm. Ambrose Heal gave the name of Tottenham Court Road a new sound to buyers of simply designed, well made things. George Jack became known both as the designer of many rich pieces of furniture and as a most gifted wood carver. He and Frederic Stuttig have brought new life into the decaying traditions of carved and gilded picture and mirror frames; they also did admirable gesso work, decorated with gold and colours. Many chairs, of new and serviceable design, were exhibited, including good basket-work seats made by Harry H. Peach. Examples of good upholstered furniture, however, were strangely lacking. Few workers appear to have studied closely the essentially comfortable art of upholstery, in which British craftsmen excelled in by-gone times. A wealth of those small articles in which the woodworker always revels—stationery and music cabinets, work boxes, caskets and so on—appeared at all exhibitions. These, with all their many delightful kinds of decoration by means of gesso, inlay, veneers or painting, had much pleasing ingenuity. A good deal of cabinet work enriched with patterns skilfully painted in colours was produced by several workers, Alfred H. Powell amongst others. In J. D. Crace (1838–1919) was combined a designer of furniture and a decorator whose scholarly and refined work was full of sound traditional knowledge.

Ceramics.—The death of William de Morgan (1839–1917), the famous potter who made a new reputation as a novelist at an age when most men retire from active work, removed a great figure from the scene. The wonderful display of his work brought together in Paris in 1914 rivalled the glories of early Persian wares, with its fine technique, noble, vigorously drawn decoration, and splendid play of lustre and colour. Bowls and vases of fine character, by Thackeray Turner, were exhibited in Paris and at the Royal Academy, together with specimens of the interesting "Ruskin" ware of W. Howson Taylor, and some of the attractive work of W. Harrison Cowlishaw. A number of excellent vases, some modelled in the forms of amusingly serious birds, by the skilful brothers Martin, were also exhibited in Paris and other places. Alfred H. Powell and his wife, Louise Lessore Powell, decorated many pieces, and sets, of Wedgwood ware, with exquisite designs painted in their sure, clear style. Exhibits by Doulton & Co. must be mentioned, and also the charming little modelled figures of Mrs. Phoebe Stabler.

Textiles and Wallpapers.—The simplicity of house decoration of the present day is in marked contrast to the lavish use of patterns customary in the latter half of the 19th century. It would appear, perhaps, that William Morris, the greatest pattern designer of our age, was himself an adventurer in the two extremes of taste; his own use of the splendid woven and printed textiles and wallpapers that he designed with such apparent ease, set the fashion in one direction, whilst the ascetic cult of whitewash and plain linen seems also to derive from him. The extensive collection of Morris' textiles and wallpapers brought together at Paris included a number of his precious original drawings for these. Their beautiful drawing and colour and noble sense of design, made distressingly apparent the ignorant carelessness of what now passes for pattern designing in so many quarters. A number of designers of fabrics and wallpapers founded their work on well-tried principles. H. Dearle followed closely the tradition of Morris. The designs of C. F. A. Voysey showed pleasing originality, and those of Heywood Sumner the stamp of sound style. Metford Warner, first in the production of fine wallpapers, had also the distinction of being the first manufacturer to attach to his wares the names of the many distinguished designers whom his taste discovered and employed. Allan F. Vigers was a careful observer of natural forms, which he treated with well-considered formality. Sidney Mawson is a bold and vigorous draughtsman who leaned towards realism. Joseph M. Doran produced many well-planned, dignified designs. In sumptuous silks and velvets Sir Frank Warner worthily maintained the traditions of the "grand style" of the Venetians and Genoese. Luther Hooper, the historian of weaving, and a master of the intricate contrivances of the loom, was also a brilliant designer. Edmund Hunter produced a great number of distinctive stuffs, of his own design. E. W. Tristram, an excellent designer and draughtsman, and J. F. Flanagan wove interesting fabrics for hangings and upholstery purposes. The beautiful handwoven linens of Annie Garnett became well known; and Katherine Grasett wove fine stuffs of many kinds. Some tapestries were produced at the workshop started by Morris at Merton, and new adventures in this art were undertaken elsewhere. In Paris and at the Royal Academy were seen the last work in pattern designing of Walter Crane, whose peculiar genius gave such charm to so many fabrics and wallpapers. In Louis Foreman Day (1845–1910) was lost another designer whose work was well known to the last generation of decorators. His text books on various arts and crafts were the first of their kind, and ran through many editions.

Embroidery.—In the particularly feminine art of embroidery many workers experimented in new directions. In one vein the embroideries of May Morris and her fellow workers and pupils, recalling the designs of, or actually designed by, William Morris, Philip Webb (1831–1915) and others of a school that was preëminent in flowing patterns of large scale, have added splendour to many exhibitions during the decade 1910–20. Mrs. Newall, of Fisherton de la Mere, an embroiderer whose work is of another type, produced a

number of large hangings and other pieces of quite modern character. Her enthusiasm and knowledge trained a large following of pupils. Mrs. Archibald Christie's bed spreads, curtains, and household linens of various kinds, ranging from heavy appliqué work to things of gossamer-like substance, showed a break in yet another direction. They had an attractive touch of the past, springing from a new use of half-forgotten technical methods, rather than from archaic turns of design. The collection of very original samplers and other specimens, by Mrs. Christie and her pupils, illustrating a wide range of stitches, was a novel feature of the Royal Academy exhibition. Mary J. Newill, another distinguished embroiderer, carried out at the Birmingham School of Art some interesting experiments in directly stitched embroidery, that, for its effect, relies more upon interest of subject and colour scheme, than upon diversity of texture. Louisa F. Pesel followed Eastern models, in the intricate workings of which she is an expert exponent.

Metal Work.—Amongst metal workers Henry Wilson occupied a most prominent place. Equally successful in a great door of bronze, a silver cup or a minute piece of enamelled jewellery, his many-sided genius recalled the versatile masters of the greatest ages of craftsmanship. His bracelets, tiaras, brooches, and other beautiful jewellery, with their delicately modelled figures and rich ornaments, chased, or enamelled in glowing colours, had wonderful brilliance and character. His ecclesiastical work broke entirely with hackneyed fashions, but maintained the great spirit of significant magnificence. The collection of Wilson's work shown in Paris will long be remembered. R. Catterson Smith, another metal worker, silversmith and jeweller, with a wide range of other activities, was an inspiring teacher; he made famous the Birmingham School of Art, of which he was principal. Amongst other silversmiths and jewellers whose work combined sound craftsmanship and distinctive design, J. Paul Cooper and Arthur Gaskin claim special attention. W. Bainbridge Reynolds's varied work showed great individuality and skill. As a designer and maker of fine serviceable things for domestic use W. A. S. Benson became well known. Amongst the remarkable metal work shown in Paris in 1914, the crown, sceptre, ring and sword worn by H. R. H. the Prince of Wales at his investiture at Carnarvon in 1911, had a romantic interest. These, designed and modelled by Sir W. Goscombe John, were made by Messrs. Garrard & Co. The death of Henry Longden (1831-1920) removed a master metal worker of sound taste and wide knowledge, who was one of the pioneers of the arts and crafts movement.

Stained Glass and Mosaic Work.—The stained glass of Christopher W. Whall showed a perfect combination of artist and master craftsman. Beautiful drawing, mastery of colour and design, united with sure technical knowledge in work of the highest rank. His rare capacity in training others surrounded him with a group of brilliant pupils, amongst whom Karl Parsons was prominent. Louis Davis was another glass painter who was a thorough master of his craft. Prof. Selwyn Image's glass was dignified in design and fine in drawing. In mosaic the most impressive modern work decorates the vault of the chapel of St. Andrew, designed by Robert W. S. Weir, in the cathedral at Westminster. This chapel, opened in 1915, is remarkable for the skilful arrangement of the rich marbles of its wall decoration, the slender dignity of its exquisite metal screen, its inlaid choir stalls (the work of the late Ernest W. Gimson), and the glitter of its romantic mosaics. It is the most perfect expression of the particular style of decoration adopted in the cathedral that has yet been achieved. The excellence of the mosaics is due to the technical knowledge of Gaetano Meo, and the fine decorative sense of their designer, George Jack.

Other Crafts that claim attention include the art of the poster, which may be deemed a temporary form of mural decoration. This became, at the hands of F. Ernest Jackson and his collaborators, a thing of such interest that its evanescent nature is a matter of regret, rather than of satisfaction, as is too often the case. George Kruger Gray designed heraldic work of many kinds, in the finest tradition of an art in which tradition is an essential quality. Cecil Thomas's engraved and sculptured gems and seals were worthy examples of an ancient craft. The modelled plaster work of Ernest W. Gimson, Laurence Turner, Norman Jewson and others was a lively rebirth of what had become a mechanical form of ornament. Several workers in architectural leadwork rainwater pipe heads, sundials and other things, derived inspiration from Prof. W. R. Lethaby, and technical knowledge from the researches of Francis W. Troup. Prof. Thomas Okey added to his many claims to fame the distinction of being the best modern basket-maker. The beautiful table glass designed by Philip Webb for William Morris in 1860 and made by James Powell & Sons, which was exhibited in Paris in 1914, showed modern design and workmanship, equalling, if not excelling, anything of the kind produced in the past. The death of Philip Webb, than whom none was more distinguished amongst that small [illegible] of great architects that made the latter half of the 19th century and so remarkable in the annals of domestic architecture, was also a [illegible] to the many lesser crafts in which his commanding genius found expression. Everything he touched, church or mansion, table glass or embroidery, showed the completeness of his knowledge and the stamp of his individuality.

Art Workers' Guild.—From its foundation, in 1884, the Art Workers' Guild has been the inspiring and directing force of the arts and crafts movement in England. At the meetings of this close, but eminently hospitable body, the far-reaching activities of the world of art have been discussed, with the insight peculiar to practical minds, by the most notable workers of the past 30 years, and influenced in a remarkable way. Perhaps the most striking quality of craftsmen is their versatility. They turn readily from one kind of work to another with an ease and certainty bewildering to the spectator. Norman Shaw (1831-1912) and Philip Webb, typical giants of the last generation, were great in several arts, any one of which might have occupied an individual for the whole term of life, and they added to these preëminence in architecture. William Morris himself was not only master of a score of arts, but preëminent in all.

United States

The first American arts and crafts society was instituted in 1897 at Hull House, Chicago. The Boston Society of Arts and Crafts was formed a few months later. Following these, societies multiplied rapidly until there was no large city and scarcely a town or village which had not its local group. New York's society dates from 1904, and was for some years affiliated with the National Arts Club and called the National Society of Craftsmen, numbering shortly after its founding between four and five hundred members. Later, ending this affiliation, it took the name of the New York Society of Craftsmen. At Philadelphia a house was fitted up, with individual studios in connexion with the salesroom. Detroit and Milwaukee early developed active art centres, each with its own building, exhibition rooms and classes. Besides these regular arts and crafts societies there grew up many so-called "gift-shops," with or without tea-rooms.

Industries like those of England were instituted from time to time, but did not flourish as well as the cooperative groups. That of the Abnake Rug, at Pequaket, N.H., one of the early and most successful, was conducted by Mrs. Albee who originated the patterns from Indian designs, the name being that of a tribe of Indians formerly inhabiting the region. These rugs, made as were the old hooked rugs, were worked by the country women of the neighbourhood in their own homes and paid for by the square foot. As they suited well the "craftsman" style of furniture, they were in great demand, but the undertaking proved too burdensome, and was given up. Similar industries were conducted in Cranberry I., Me., and in the mountains of the south. Industrial and experimental groups were conducted in connexion with colleges, that of Alfred, N.Y., and of Sophie Newcomb College, New Orleans, being successful examples. At the latter a style of pottery was developed, produced by graduate students and sold by the college for them, in which the motifs were taken from the native flora. A similar group in embroidery created some beautiful things in stitchery and appliqué. Semi-commercial enterprises also sprung up which were varied in their plan and output. The earliest and best known is that of the Rookwood Pottery at Cincinnati, Ohio. The Grueby Pottery, although for financial reasons short-lived, was most distinctive, as was the Dedham ware. Both of these came from the neighbourhood of Boston, where too was the Paul Revere Pottery, made under the steeple of the very church from which hung the historic lantern. From here came also a heavy ware, suitable for children's use, the decoration of which was done by girls of high-school age, under careful direction, the industry having developed from classes in a girls' club. In New York the Tiffany stained glass and opalescent ware were celebrated. The Herter looms, also in New York, produced beautiful tapestries and hangings. From Doylestown, Pa., came the Mercer tiles of unusually artistic design and workmanship. The original patterns were taken from the doors of porcelain stoves brought over by the "Pennsylvania Dutch" settlers of that region. These are a few of the most prominent of the many art industries through the United States. The craftsman furniture paved the way for other styles more or less modelled upon it, the furniture of the Erskine-Danforth Co., New York, being perhaps most nearly in line with the spirit of simplicity associated with the arts and crafts idea.

Individual societies, as has been said, sprung up spontaneously, and although there was a kind of freemasonry among them each

remained independent and unattached. To bring them together and to unify the movement there was formed in Boston 1907, just 10 years after the founding of the first society, a league of handicraft societies, 20 coming together as charter members. In 1912 the National League of Handicraft Societies represented about 40 arts and crafts societies, of which many had a membership well into the hundreds. Its aim was to form a clearing house for the movement and to do statistical and educational work not within the scope of any one society. It supported a travelling exhibition of handicraft which was sent on request to places in which excellent work of this kind could not be seen, and a travelling library of technical works and other appropriate books not so well selected or easily obtainable outside of the great cities. The founding of this league, of itself, indicates the existence of strong and enterprising societies and the strength of the handicraft idea. When in 1909 the American Federation of Arts was formed at Washington, it included the handicrafts as well as the so-called fine arts, and as the handicraft department covered much of the work of the league, the latter was merged, in 1912, into the arts and crafts department of the federation. The American Federation of Arts aimed to organize a federation of all institutions, societies, city and village improvement associations, and school and other organizations in the United States, whose purpose was to promote the study and application of art, and to cultivate public taste. The educational work was along three lines: it sent out travelling exhibitions of work of a high standard; it circulated typewritten lectures pertaining to the arts and crafts; and it published a monthly magazine.

Early in its history the Boston society issued each month a booklet containing an essay upon some craft with other appropriate matter. This was taken over by the National League of Handicraft Societies and published, with a few changes, as the monthly magazine *Handicraft*. In 1909 the National Society of Craftsmen, N.Y., brought out an eight-page folder each month called the *Arts & Crafts Bulletin*. This flourished for two years and then became *The Arts & Crafts Magazine*, published independently at Washington's Crossing, N.J. Both this and *Handicraft* were bought out in 1913 by the *Industrial Arts Magazine*. Meanwhile there had been published in connexion with the craftsman furniture a distinctive magazine, *The Craftsman*, which did a great deal to develop taste along these lines. *The Philistine*, describing the industry at East Aurora, N.Y., helped to spread the Morris idea as a practical one. In 1921 the handicraft idea had no organ of its own except as represented in the *American Magazine of Art* of the Federation.

In 1914 the Art Alliance was formed with the express purpose of bringing together the artist and the manufacturer. Difficult as this appeared at the time it proved its value. The alliance numbered in 1920 1,000 members in the United States and Canada with others in England, France, Germany and in Manila. Manufacturers pay a membership fee of $50 a year, artist members $5, on the theory that the former receive the greater benefits. In Dec. 1920 the fifth annual exhibition of the alliance was held in the Bush Terminal Building, New York City, at which 3,500 designs from 34 states were shown; $2,000 was distributed in prizes by the manufacturers for designs to be used commercially. In accordance with the tendency to amalgamation, four societies—the Art Alliance, the New York Society of Craftsmen, the Pictorial Photographers of America and the Society of Illustrators—united in the spring of 1920 to secure a local Art Centre, or Home of the Arts, in New York City, in which societies, hitherto unrelated, might have common offices, exhibition rooms, meeting rooms, etc., with a dining hall and a certain number of studios. Stock was issued at $10 a share and in a short time enough subscribed to permit of the purchase of two houses at 65–67 East 56th Street. The Art Centre was formally opened Nov. 1921.

Another evidence of the interest taken in industrial art is the formation of the Industrial Arts Survey, backed by the state of New York, with an office in Cooper Union, New York City. The aim is to investigate the development of the arts in America, especially as compared with those of Europe, in order to stimulate their development. In this the public schools and the School Arts League have aided. Also in this work and especially in the general education of the public the museums all over the country have successfully coöperated. At the Metropolitan Museum of Art, New York City, there was held in Jan. 1921 a remarkable and beautiful display of industrial art, the Fifth Exhibition of Current Work by Manufacturers and Designers. (M. B. E.)

ARTSIBASHEV, MIKHAIL PETROVICH (1878–), Russian novelist, was born in South Russia Oct. 18 1878. His family was of Tartar descent, and on the mother's side he was a great-grandson of Kosciusko. He at first followed an artistic career, and attained some fame as a caricaturist, but subsequently began writing short stories, followed by novels. In 1912 he was imprisoned for several months by the Imperial Government as a revolutionary.

His collected works were published in Moscow in 10 vols., 1912–7, and contain:—*Razskazi* (Tales); *U poslednei chertiy* (At the Extreme Limit, translated into English as *The Breaking Point*, 1915); *Zakon dikarya* (The Law of a Misanthrope); *Revnost* (Jealousy); *Voina* (War, translated into English 1918 under the same title) and *Sanin* (translated into English as *Sanine*, 1915).

ARZ VON STRAUSSENBURG, ARTHUR, Baron (1857–), Austro-Hungarian general, was born at Hermannstadt, Transylvania, and served in the infantry and on the general staff. At the outbreak of the World War he was the chief of a section in the Ministry of War, but hurried to the Russian front, where he commanded first the 15th Div., and later the VI. Army Corps. He shared the success of the battle of Limanowa-Lapanow in Dec. 1914, which definitely stopped the Russian offensive, with Col.-Gen. Freiherr von Roth (b. at Trent in 1850). In the spring and summer campaign of 1915 Arz and his corps acted with Mackensen's German army, and fought with special success in the neighbourhood of Przemysl and in the further course of the campaign captured the fortress of Brest-Litovsk. Appointed to the command of the 1st Army in the summer of 1916, he had as a Transylvanian to defend that country against the Rumanians, whom he, in conjunction with Falkenhayn's German troops, drove back into Wallachia. After the retirement of Conrad von Hötzendorff, Arz was appointed by the Emperor Charles chief of the general staff of the Austro-Hungarian armies, the department of operations being conducted under his direction by the able Maj.-Gen. Alfred, Freiherr von Waldstätten (b. at Vienna in 1872).

ASCHE, OSCAR (1872–), English actor, was born at Geelong, Victoria, Australia, June 26 1872. Norwegian by descent, he studied for the stage at Christiania. After appearing at the Opéra Comique, London, in 1893, he joined F. R. Benson's company for eight years, playing numerous parts in Shakespearean and old English comedy. He next played Maldonado in Pinero's *Iris* at the Garrick theatre, London. In 1902 and again in 1904 he played in Shakespeare with Herbert Tree at His Majesty's theatre. He began management at the Adelphi at the close of that year, and, with his wife, Miss Lily Brayton, presented *The Taming of the Shrew*, *Midsummer Night's Dream* and *Measure for Measure*. In 1907 he presented Laurence Binyon's *Attila* at His Majesty's theatre and also *As You Like It* and other Shakespeare plays. Subsequently to 1911 he specialized in the presentation of spectacular Oriental dramas, the best known being *Kismet*, played at the Garrick theatre, London 1911–2, and *Chu Chin Chow*, first produced at His Majesty's Aug. 31 1916 which ran for nearly five years. In Oct. 1921 he produced *Cairo*.

ASHANTI (*see* 2.724).—By an Order in Council dated Oct. 22 1906, the boundaries between the Ashanti Protectorate and the Crown Colony of the Gold Coast, of which the former is the principal dependency, were readjusted and defined with due regard to tribal lands and natural features. For administrative purposes Ashanti has been divided into four provinces: the Central, the Southern, the Western and the Northern, each of which is under the charge of a provincial commissioner. The capitals of the provinces at which these officers have their headquarters are respectively Kumasi, which is also the capital of Ashanti; Obuasi, a considerable town situated upon the Kumasi-Sekondi railway some 50 m. due S. of Kumasi, and the principal centre of the Ashanti Goldfields Corporation; Sunyani and Kintampo. Each province is divided up into districts which are under the charge of district commissioners, who in their turn are aided by a staff of assistant district commissioners. A chief commissioner who resides at Kumasi, and who is assisted, as in former days the King of Ashanti was similarly assisted, by a council of Kumasi chiefs, is immediately responsible to the governor of the Gold Coast for the administration of Ashanti. This post was filled until early in 1920 by Mr. (afterwards Sir Francis) Fuller, who was succeeded by Mr. Charles Harper.

As in the days preceding the conquest, the principal tribes, which at that time formed the Ashanti Confederation under the hegemony of Kumasi, are under the immediate rule of their own tribal organizations which, in each case, consist of an *omanhene*, or paramount chief, and of a number of *ohene*, or subordinate chiefs, each one of whom is the overlord of a section of the tribe, with minor chiefs and headmen under him. All these posts are filled, when a vacancy is occasioned by the death or the destoolment of their occupants, by men freely chosen by the tribe, or by the section of the tribe over

which they are called upon to preside, the selection being, however, confined to candidates belonging to one or more noble families in which the office of chief is to this extent hereditary. Descent is traced exclusively through the female side; wherefore a chief is succeeded by one of his brothers, by one of the sons of one or other of his mother's sisters, or by the sons of one of his own sisters, but never by any of his own sons. This causes the position of the queen-mother in a tribe to be one of great prominence, and it not uncommonly happens that, when a doubt arises as to the rival merits of two or more candidates for a vacant office, the decision as to which shall be nominated for election by the tribe is submitted to her for determination. The *omanhene* and the various *ohene* of each tribe exercise criminal and civil jurisdiction within the tribal boundaries, the extent of such jurisdiction being limited by the orders of the chief commissioner, issued with the approval of the Governor of the Gold Coast. Courts possessing progressively wider powers are presided over by the assistant district commissioners, district commissioners and provincial commissioners; and until recently all capital cases and civil cases of importance were tried and determined in the court of the chief commissioner. Shortly before 1921, however, a post of judicial commissioner was created, which is held by a qualified barrister, whose duty it is to try all capital and all important civil cases, and to revise the judicial work of the officers of the administrative staff. Lawyers are not permitted to practise in any of the courts of Ashanti, and the chiefs have taken up a very strong resistant attitude whenever their admission has been mooted. They deprecate action which they believe will cause justice to become expensive and which is calculated to promote ruinous litigation among the tribes, especially in connexion with land disputes.

After the conquest in 1900, the internal peace of Ashanti remained undisturbed, and the decade immediately preceding the outbreak of the World War was marked by considerable progress. The administrative staff was greatly increased; a first-class motor road from Kumasi to Ejura, a distance of 61 m., was completed in June 1912; schools were established by Government at Kumasi and Sunyani to supplement the 24 schools which in 1913 were being conducted by the Basle Mission; and the cultivation of cocoa spread from the colony, where it had already made great progress, into Ashanti.

No idea of the true financial position of Ashanti is conveyed by the published statistics, as the Protectorate is not credited with the customs duties on articles designed for consumption within it, which are collected at the ports of entry on the Gold Coast, nor yet with the revenue derived from goods carried on the Sekondi-Kumasi railway. On the other hand, the main expenditure upon the Gold Coast regiment of the West Africa frontier force is shown in the accounts as a charge against Ashanti, Kumasi being the headquarters of that corps, though the regiment is no longer even nominally maintained to insure the tranquillity of the local population. In 1913 the total value of the exports from Ashanti amounted to £1,155,378, the items being gold worth £475,089, cocoa worth £400,000, kola nuts worth £126,000, rubber worth £75,209, cattle and sheep worth £45,600 and hides worth £33,480. By the end of 1913 good paths, suitable for bicyclists, had been made and were being maintained by the various tribal organizations throughout the greater part of Ashanti.

In his annual report for 1914, Mr. (afterwards Sir Francis) Fuller was able to record "the unanimous and deep loyalty expressed by all the Ashanti chiefs towards their Sovereign and Government on the outbreak of war"; and so complete was the confidence felt in these sentiments that from Aug. 1914 onward the Government of the Gold Coast was able almost totally to denude Ashanti of troops in order to dispatch expeditionary forces to take part successively in the Togoland, Cameroon and East African campaigns. Ashanti provided few recruits for these forces, the people disliking the military discipline which is so dissimilar to their own methods of warfare, and the spread of permanent cultivation (cocoa) having attached them to the soil to an extent unknown in former times. Their loyalty, however, remained unabated throughout; and the years of the war were marked by great local development.

By the end of 1918 over 380 m. of roads suitable for motor traffic were available, most of which had been constructed by the tribes themselves under European supervision, and large numbers of lorries were at work carrying the cocoa crop to rail-head. The exports in 1919 were valued at £2,433,205 (gold, £421,696; cocoa, £1,425,-185; kola nuts, £493,680; rubber, £632; cattle and sheep, £70,000; hides and skins, £7,012; snails, £10,000; miscellaneous £5,000). The value of the imports had risen to £1,773,257, the principal items being European merchandise worth £1,201,257, cattle worth £370,000, sheep and goats worth £100,000 and dawadawa and shea butter worth £92,000. The quantity of gold exported had slightly declined, but the export of cocoa had risen from 8,693 tons in 1913 to 32,000 tons in 1919, and the increased imports of live stock are due to the enhanced consumption of meat by the rural population alike in Ashanti and in the colony as a result of the wealth consequent upon the spread of cocoa cultivation. Wild African rubber had ceased to be worked. Large numbers of live stock and snails, which are a local delicacy, were reëxported to the Gold Coast.

ASHBOURNE, EDWARD GIBSON, 1st Baron (1837–1913), Irish lawyer and politician, was born in Dublin Sept. 4 1837, and was educated at Trinity College, Dublin. He was called to the Irish bar in 1860, and in 1872 became a Q.C. In 1875 he was elected for Dublin University as a Conservative, and in 1877 became attorney-general for Ireland in Disraeli's Government. In 1885 he was made Lord Chancellor of Ireland with a seat in the Cabinet, and raised to the peerage, holding the same office in the Conservative Governments of 1886–92 and 1895–1905. Lord Ashbourne took a prominent part in the early negotiations for land purchase in Ireland. He died in London May 22 1913, and was succeeded as 2nd baron by his eldest son, William Gibson (b. 1868).

ASHFIELD, ALBERT HENRY STANLEY, 1st Baron (1874–), British politician and man of business, was born at Derby Nov. 8 1874. He spent his early years in the United States, and was educated at various American technical schools and colleges. He entered a railway office and had a successful business career, becoming general manager of the Detroit United Railways and the Public Service Railways of New Jersey. In 1910 he returned to England, and took up the position of managing director of the traffic combine which included the Underground Electric Railway Co. and the London General Omnibus Co. In 1914 he was knighted. On the formation of Mr. Lloyd George's Government in 1916 Sir Albert Stanley was elected to Parliament for Ashton-under-Lyne, being included in the Cabinet as President of the Board of Trade. He was a notable instance of a minister selected as a "business man" and not for any of the usual political considerations. He retained his office until May 1919, when he resigned and was raised to the peerage.

ASHLEY, SIR WILLIAM JAMES (1860–), English economist (*see* 2.733*), served during the World War on a number of Government committees, especially with regard to food prices and the cost of living. He was a member of the Consumers' Council appointed in 1918 to assist the Ministry of Food. In 1913 he had been president of the Economic History section of the International Historical Congress, and in 1914 he was one of the authors of the report on Industrial Unrest published by the Unionist Social Reform Committee. In 1912 he published *The Rise in Prices* and *Gold and Prices*, and in 1914 *The Economic Organisation of England.* He was knighted in 1917.

ASHWELL, LENA (1872–), English actress (*see* 2.734), at the outbreak of the World War organized a Women's Emergency Corps for rendering services of all kinds to the Allied forces and to refugees, as well as assistance to women at home thrown out of work by the dislocation of industry. She also formed a company of actors and musicians and went with them to France, where they provided excellent and much-appreciated entertainment to the troops when resting. She was made O.B.E. on the institution of the Order of the British Empire Aug. 24 1917.

ASIAGO, BATTLE OF, 1916.—The Asiago plateau was the scene of various battles on the Italian front during the World War (*see* Italian Campaigns); but what is called preëminently

** These figures indicate the volume and page number of the previous article.*

remained independent and unattached. To bring them together and to unify the movement there was formed in Boston 1907, just 10 years after the founding of the first society, a league of handicraft societies, 20 coming together as charter members. In 1912 the National League of Handicraft Societies represented about 40 arts and crafts societies, of which many had a membership well into the hundreds. Its aim was to form a clearing house for the movement and to do statistical and educational work not within the scope of any one society. It supported a travelling exhibition of handicraft which was sent on request to places in which excellent work of this kind could not be seen, and a travelling library of technical works and other appropriate books not so well selected or easily obtainable outside of the great cities. The founding of this league, of itself, indicates the existence of strong and enterprising societies and the strength of the handicraft idea. When in 1909 the American Federation of Arts was formed at Washington, it included the handicrafts as well as the so-called fine arts, and as the handicraft department covered much of the work of the league, the latter was merged, in 1912, into the arts and crafts department of the federation. The American Federation of Arts aimed to organize a federation of all institutions, societies, city and village improvement associations, and school and other organizations in the United States, whose purpose was to promote the study and application of art, and to cultivate public taste. The educational work was along three lines: it sent out travelling exhibitions of work of a high standard; it circulated typewritten lectures pertaining to the arts and crafts; and it published a monthly magazine.

Early in its history the Boston society issued each month a booklet containing an essay upon some craft with other appropriate matter. This was taken over by the National League of Handicraft Societies and published, with a few changes, as the monthly magazine *Handicraft.* In 1909 the National Society of Craftsmen, N.Y., brought out an eight-page folder each month called the *Arts & Crafts Bulletin.* This flourished for two years and then became *The Arts & Crafts Magazine*, published independently at Washington's Crossing, N.J. Both this and *Handicraft* were bought out in 1913 by the *Industrial Arts Magazine.* Meanwhile there had been published in connexion with the craftsman furniture a distinctive magazine, *The Craftsman*, which did a great deal to develop taste along these lines. *The Philistine*, describing the industry at East Aurora, N.Y., helped to spread the Morris idea as a practical one. In 1921 the handicraft idea had no organ of its own except as represented in the *American Magazine of Art* of the Federation.

In 1914 the Art Alliance was formed with the express purpose of bringing together the artist and the manufacturer. Difficult as this appeared at the time it proved its value. The alliance numbered in 1920 1,000 members in the United States and Canada with others in England, France, Germany and in Manila. Manufacturers pay a membership fee of \$50 a year, artist members \$5, on the theory that the former receive the greater benefits. In Dec. 1920 the fifth annual exhibition of the alliance was held in the Bush Terminal Building, New York City, at which 3,500 designs from 34 states were shown; \$2,000 was distributed in prizes by the manufacturers for designs to be used commercially. In accordance with the tendency to amalgamation, four societies—the Art Alliance, the New York Society of Craftsmen, the Pictorial Photographers of America and the Society of Illustrators—united in the spring of 1920 to secure a local Art Centre, or Home of the Arts, in New York City, in which societies, hitherto unrelated, might have common offices, exhibition rooms, meeting rooms, etc., with a dining hall and a certain number of studios. Stock was issued at \$10 a share and in a short time enough subscribed to permit of the purchase of two houses at 65–67 East 50th Street. The Art Centre was formally opened Nov. 1921.

Another evidence of the interest taken in industrial art is the formation of the Industrial Arts Survey, backed by the state of New York, with an office in Cooper Union, New York City. The aim is to investigate the development of the arts in America, especially as compared with those of Europe, in order to stimulate their development. In this the public schools and the School Arts League have aided. Also in this work and especially in the general education of the public the museums all over the country have successfully coöperated. At the Metropolitan Museum of Art, New York City, there was held in Jan. 1921 a remarkable and beautiful display of industrial art, the Fifth Exhibition of Current Work by Manufacturers and Designers. (M. B. E.)

ARTSIBASHEV, MIKHAIL PETROVICH (1878–), Russian novelist, was born in South Russia Oct. 18 1878. His family was of Tartar descent, and on the mother's side he was a great-grandson of Kosciusko. He at first followed an artistic career, and attained some fame as a caricaturist, but subsequently began writing short stories, followed by novels. In 1912 he was imprisoned for several months by the Imperial Government as a revolutionary.

His collected works were published in Moscow in 10 vols., 1912–7, and contain:—*Razskazi* (Tales); *U posledni chertiy* (At the Extreme Limit, translated into English as *The Breaking Point*, 1915); *Zakon dikarya* (The Law of a Misanthrope); *Revnost* (Jealousy); *Voina* (War, translated into English 1918 under the same title) and *Sanin* (translated into English as *Sanine*, 1915).

ARZ VON STRAUSSENBURG, ARTHUR, Baron (1857–), Austro-Hungarian general, was born at Hermannstadt, Transylvania, and served in the infantry and on the general staff. At the outbreak of the World War he was the chief of a section in the Ministry of War, but hurried to the Russian front, where he commanded first the 15th Div., and later the VI. Army Corps. He shared the success of the battle of Limanowa-Lapanow in Dec. 1914, which definitely stopped the Russian offensive, with Col.-Gen. Freiherr von Roth (b. at Trent in 1850). In the spring and summer campaign of 1915 Arz and his corps acted with Mackensen's German army, and fought with special success in the neighbourhood of Przemysl and in the further course of the campaign captured the fortress of Brest-Litovsk. Appointed to the command of the 1st Army in the summer of 1916, he had as a Transylvanian to defend that country against the Rumanians, whom he, in conjunction with Falkenhayn's German troops, drove back into Wallachia. After the retirement of Conrad von Hötzendorff, Arz was appointed by the Emperor Charles chief of the general staff of the Austro-Hungarian armies, the department of operations being conducted under his direction by the able Maj.-Gen. Alfred, Freiherr von Waldstätten (b. at Vienna in 1872).

ASCHE, OSCAR (1872–), English actor, was born at Geelong, Victoria, Australia, June 26 1872. Norwegian by descent, he studied for the stage at Christiania. After appearing at the Opéra Comique, London, in 1893, he joined F. R. Benson's company for eight years, playing numerous parts in Shakespearean and old English comedy. He next played Maldonado in Pinero's *Iris* at the Garrick theatre, London. In 1902 and again in 1904 he played in Shakespeare with Herbert Tree at His Majesty's theatre. In Oct. 1921 he produced *Cairo.*

ASHANTI (*see* 2.724).—By an Order in Council dated Oct. 22 1906, the boundaries between the Ashanti Protectorate and the Crown Colony of the Gold Coast, of which the former is the principal dependency, were readjusted and defined with due regard to tribal lands and natural features. For administrative purposes Ashanti has been divided into four provinces: the Central, the Southern, the Western and the Northern, each of which is under the charge of a provincial commissioner. The capitals of the provinces at which these officers have their headquarters are respectively Kumasi, which is also the capital of Ashanti; Obuasi, a considerable town situated upon the Kumasi-Sekondi railway some 50 m. due S. of Kumasi, and the principal centre of the Ashanti Goldfields Corporation; Sunyani and Kintampo. Each province is divided up into districts which are under the charge of district commissioners, who in their turn are aided by a staff of assistant district commissioners. A chief commissioner who resides at Kumasi, and who is assisted, as in former days the King of Ashanti was similarly assisted, by a council of Kumasi chiefs, is immediately responsible to the governor of the Gold Coast for the administration of Ashanti. This post was filled until early in 1920 by Mr. (afterwards Sir Francis) Fuller, who was succeeded by Mr. Charles Harper.

As in the days preceding the conquest, the principal tribes, which at that time formed the Ashanti Confederation under the hegemony of Kumasi, are under the immediate rule of their own tribal organizations which, in each case, consist of an *omanhene*, or paramount chief, and of a number of *ohene*, or subordinate chiefs, each one of whom is the overlord of a section of the tribe, with minor chiefs and headmen under him. All these posts are filled, when a vacancy is occasioned by the death or the destoolment of their occupants, by men freely chosen by the tribe, or by the section of the tribe over

system between the Val Lagarina and the Val Sugana, accompanied by a map showing the various lines, stating that the conditions were "re-assuring," and that the third line of defence upon which Cadorna had laid special emphasis could be considered as being in a satisfactory state of efficiency. Three days later Brusati suggested the reënforcement of two sectors of the line, that between the Vallarsa and the Val Terragnolo, and the Tonezza sector, between the Val Terragnolo and the Astico. He asked for permission to split the 9th Div., which had been given him as a reserve, and send a brigade to each of the sectors mentioned. He also asked for another division to be held in reserve about Vicenza. Cadorna was unwilling to break up the 9th Div., and ordered that it should be held in reserve at Schio, within easy reach of the Vallarsa sector, while to reënforce the Tonezza sector he dispatched an additional brigade from the general reserve. He also detailed the 27th Div., in reserve on the Tagliamento, to be ready as a further reënforcement and formed a further artillery reserve of 10 heavy batteries.

At the end of April Cadorna went to visit the lines in person. He found that while the front lines had been elaborately fortified, in various sectors the reserve lines which he had indicated as the "battle positions" were almost untouched, and parts of the front line were unsuitable for prolonged resistance. Between the Val Lagarina and the Vallarsa and along the Val Terragnolo the Italian lines formed a dangerously exposed salient, running down from the high slopes and completely dominated by the Austrian guns on Monte Biaena, Monte Ghello, Monte Finonchio and the Folgaria plateau. In the Val Sugana the same fault was observable. The forward lines on Monte Armentera and Monte Salubio were poorly adapted for defence, but had been strongly fortified, while the line east of the Maso torrent, which Cadorna had indicated as the main line of defence, had undergone little preparation. Cadorna ordered the positions to be modified. The bulk of the heavy guns were withdrawn to the second line and the work of preparation was hastened on; but the enemy attack seemed imminent, and it was impossible to set about a complete reorganization under the immediate threat.

On the wings it was possible to improve the situation. In the centre the problem was different, for here the Italians were of necessity badly placed. The salient of Soglio l'Aspio (4,375 ft.), between the frontier and the Upper Astico, was practically in the air, and could only be considered as an outpost. But the main line between the Posina and the Astico, which ran by Monte Maggio (5,730 ft.), Monte Toraro (6,175 ft.), Campomolon (6,030 ft.) and Spitz Tonezza (5,512 ft.), was not satisfactory for defensive purposes. It was close under the Austrian guns and it had no depth. Behind the line the ground falls away south-eastward in a steep glacis that drops abruptly in the end to the Posina on the south and the Astico on the east. It was owing to the essential weakness of this line and its extension northward to the west of the Val d'Assa that Cadorna had ordered the preparation of a third line of defence that ran from Cima Portule (7,570 ft.) east of the Val d'Assa and round the southern rim of the Asiago basin by Punta Corbin across the Astico to the mountains south of the Posina. This line was shown as existing upon the map sent to Cadorna on April 21 by the I. Army command. In reality little had been done beyond the tracings on the map. The project had remained a project.

On May 8 Brusati was replaced by Gen. Pecori-Giraldi, the commander of the VII. Corps (III. Army). A few days previously Cadorna had modified the system of commands in the threatened sector. Up to the time of his arrival on the I. Army front the whole line between Lake Garda and the mountains east of the Val Sugana had been included in the V. Corps command (Gen. Zoppi). The Val Lagarina and Val Sugana sectors were now placed under independent commands, and the long line held by the V. Corps was reduced to include only the hill country between the Vallarsa and the eastern edge of the Asiago plateau. On the eve of the Austrian attack the alignment of the I. Army was as follows:—West of Lake Garda the line was held by the III. Corps (two divisions) under Gen. Camerana. The Val Lagarina sector, from the lake to Zugna Torta, was held by the 37th Div. under Gen. Ricci Armani (two brigades, three battalions of Alpini, with several weak battalions of territorial Militia). The Sicilia Bde. was arriving in the Adige valley to act as a reserve. The left-hand division of the V. Corps (the 35th) was in line between the Vallarsa and the Astico, the Roma Bde. right down upon the Val Terragnolo, backed by a territorial Militia regiment in Col Santo and two Alpini battalions holding the Borcola Pass. The Ancona Bde., freshly come into line, lay from Monte Maggio to Campomolon, while the Cagliari Bde. was echeloned forward in the Soglio d'Aspio salient, and a group of Customs Guards battalions held the edge of the Val d'Astico. Two brigades of the 34th Div. and a group of Alpini held the Val d'Astico and a line that roughly followed the frontier as far as Cima Manderiolo (6,665 ft.). A third infantry brigade and two brigades of territorial Militia lay in immediate reserve. The right wing of the army, occupying the Val Sugana sector (extending to the Val Cismon), consisted of the XVIII. Corps under Gen. Etna, three infantry brigades, four battalions of Bersaglieri and six battalions of Alpini. The 9th Div. lay at Schio, ready to reënforce the Vallarsa–Val d'Astico sector, while the 10th Div. was at Bassano, and a group of Alpini was at Marostica. The 44th Div., freshly returned from Albania, was concentrating at Desenzano, and the 27th still lay on the Tagliamento, where the X. and XIV. Corps were also in readiness to leave in case of need. In all Pecori-Giraldi had at his immediate disposal 130 regular battalions, even battalions of Customs Guards and 45 battalions of territorial Militia, the latter at very low strength and of small fighting value. The 44th Div., which was not ready to move at the beginning of the battle, brought the number of regular battalions up to 142. The artillery strength consisted of 851 guns, of which 348 were of heavy or medium calibre and 259 were light guns of position.

The Austrians had a great superiority in artillery, upon which they relied for breaking their way through the Italian lines. Between the Val Lagarina and the Val Sugana were concentrated some 2,000 guns, of which nearly half were of heavy or medium calibre, including 40 305-mm. howitzers, four 380's and two or three German 420's. The attacking force was arrayed in two armies, one behind the other, Dankl's XI. Army in front with nine divisions, von Koevess's III. Army in support, with five divisions. The troops in the Val Lagarina and the Val Sugana were not included in this force, which was to make its offensive between the two valleys, where only supporting attacks were to be carried out. Krauss, as chief-of-staff of the Archduke Eugene, was opposed to the disposition of the two armies and to the limitation of the attack to the hill country. He urged that the front of attack should from the outset be divided between Dankl and von Koevess, and pressed for the adoption of his plan for the concentration of attacking masses in the valleys, especially in the Val Sugana. But the original plan, prepared in all its details by Conrad and his staff, was not modified; it would seem that the Archduke Eugene and his chief-of-staff had little freedom of action. The tactical direction of the attack was entrusted to Dankl, who had at his disposal some 180 battalions.

The offensive opened on May 14 with a very heavy bombardment along the whole line from the Val Lagarina to the Val Sugana; but the concentration of fire was most intense between the Vallarsa and the Upper Astico, and against this sector, the following day, the main infantry attack was launched. The plan was to attack first with the right wing of the XI. Army, commanded by the Archduke Charles, supported not only by its own artillery but by flanking fire from the massed guns on the Lavarone plateau. When the right wing had made sufficient ground the left wing was to come into action against the Italian line in the Seven Communes, north of the Upper Astico. On the extreme right of the attack, between the Val Lagarina and the Vallarsa, the Italians withdrew from their ill-chosen front lines, fighting steadily, and making the enemy pay for the ground gained. In the Val Terragnolo the Roma Bde. was run over by the enemy attack. Many prisoners were taken, and the second line, which was withdrawn in accordance with the general instructions given by Cadorna, came back in some disorder.

Against the forward line between Monte Maronia and Soglio d'Aspio the Austrian attack made no headway at first, the Cagliari Bde. and the Alpini holding firmly to their positions, but in the end the first line was occupied, the Italians retiring to the main line of defence, which ran from Monte Maggio by Campomolon to Spitz Tonezza. The Italian right was so far not heavily attacked, and demonstrative attacks by the Austrians in the Val Sugana were readily repulsed. Cadorna transferred his staff from Udine to Thiene on May 16, and next day he found a critical situation on his left. The Roma Bde., or rather what was left of it, was coming back in the Vallarsa, and Col Santo had been evacuated by the territorials, while the command of the sector had lost touch with the Alpine battalions. In the centre, too, the situation was bad. The Campomolon line was being strongly attacked, and showed signs of yielding, though reënforcements from the 9th Div. had been promptly dispatched. The line had been insufficiently prepared, and was being methodically knocked to bits by the very heavy fire of the Austrian big guns. But the chief danger lay on the left, where there was little to stop the Austrian advance between the Vallarsa and the Val Terragnolo. Here, too, practically nothing had been done to prepare the reserve positions, and owing to a mistaken order the retiring troops had not occupied Monte Pasubio, the key position now that Col Santo had gone. The Volturno Bde., of the 10th Div., which was on its way to reënforce another threatened sector, was diverted to the more critical point. A battalion was hurried up in motor lorries, and marched up to Pasubio by the Passo di Xamo. They arrived after a night march, in the nick of time. Two hours later the first Austrian patrols appeared and were quickly repulsed. The rest of the Volturno Bde. followed, and held the position till they were relieved and reënforced by the 44th Division. By May 19 the Austrians were attacking hard all along the line to which the Italians had retired, from Coni Zugna and the Passo di Buole to Pasubio, and the Campomolon line had gone. On May 18 the Austrian attacks, supported by very violent artillery fire, broke the front of the Ancona Bde., and the rest of the 35th Div., threatened on the flank, withdrew during the night. The retreat was covered by the Vicenza battalion of Alpini, who fought a gallant rear-guard action, and a strong counter-attack by the group of Alpini from Marostica checked the Austrian pursuit. The 35th Div., with its reënforcements from the 9th, came back to the line Monte Aralta (south of the Posina)–Monte Cimone–Barcarola, but the Italian centre was now broken. There were gaps both to the right and left of the 35th, though the Alpini were holding north of the Posina and the 27th Div. was coming up rapidly to the valley.

It was a critical moment for the defending army. The Austrian right was increasing the pressure against the positions west of the Vallarsa, and was collecting forces for the first of the long series of attacks against Pasubio, which was only lightly held. The 44th Div. was on its way to the front, but had not yet arrived, and a large number of the guns in this sector had been destroyed prematurely, in the belief that retreat was imminent. There was breathing space for a moment in the centre, but the Austrian left now came into action, Krautwald von Annan's III. Corps being launched against the Italian 34th Division. Ample Italian reserves were now on the move, the XIV. Corps being *en route* to fill the gap between the 35th and 34th Divs. and reënforce the latter, but it was a race. Krauss blames the Austrian XX. Corps (Archduke Charles) for waiting till the guns could be brought up to support a new attack instead of driving through at once to Arsiero with all available troops. Perhaps a column, perhaps a strong force, might have pushed straight on to Arsiero and beyond; and if so, it might have gone hard with the Italians. The risk was not taken, and the short respite gave time to close the doors in the face of the invader.

The course of the battle, with the necessity of bringing up reserve divisions, led to a reorganization of the attacking forces, von Koevess taking command of the left wing and Dankl of the right. In the Vallarsa and Pasubio sector the attack developed strongly. The advance along the ridge from Zugna Torta, which had been throughout stubbornly contested by the Italians, had been definitely checked by a regiment of the Taro Bde. at Malga Zugna, and the Austrians endeavoured to break through by coming up from the Vallarsa against Passo di Buole. At the same time Pasubio was assailed with the utmost determination. Farther north the Archduke Charles was waiting for his guns and for reserves, and between him and the III. Corps Kirchbach's I. Corps was coming into action. The III. Corps was now hammering against the Italian 34th Div., whose position was precarious, and although Etna's Val Sugana troops had held their own against various tentative attacks, they were withdrawn to the second line of defence.

Although the wings were holding, the situation in the centre was very grave, and Cadorna considered that if the Austrians were able to concentrate on the weak spot and keep up the impetus of their attack they might succeed in breaking through to the plain. On May 20 he went to Udine, and after consultation with the Duke of Aosta and Frugoni gave orders for the concentration of a reserve army in the Venetian plain. The movement of these troops, which were placed under the command of Frugoni, began on the night of May 21, by road: the railways were occupied with the transport of I. Army reserves (the X. Corps and various other units), and were not available till May 26. The first four corps of this reserve army (the V.), which were made up of units drawn from the II. and III. Armies, were ready on June 2.

Meanwhile the Austrians were continuing their advance in the centre, but the situation on the Italian left was improving. By May 22 the 44th Div., commanded by Gen. Bertotti, was in solid possession of both sides of the Vallarsa road and of Pasubio, and in touch with Ricci Armani on its left. The latter was holding firmly on Coni Zugna and the Passo di Buole, and neither here nor on Pasubio could the repeated attacks of the Austrian right make any impression. On May 24 a desperate effort was made to storm the Passo di Buole and Pasubio, but the Sicilia and Taro Bdes., who held the Zugna ridge, and the right wing of the 44th Div. on Pasubio, repulsed the onset with very heavy losses. The columns attacking Passo di Buole suffered heavily from the flanking fire of the 44th Div. guns in the Vallarsa. The left wing of the division was not attacked in force and Bertotti was able to assist Ricci Armani with his guns. Next day the attack was renewed, heavy columns coming up the slopes against the Passo di Buole, only to be thrown back, broken and decimated, one brigade being practically destroyed. The last attack in force was on May 30, when repeated efforts were made to storm the Pass, in vain. Although further attacks were made after this date the fighting never again reached the same intensity. The Austrian losses had been too heavy for them to continue their attacks in mass, and their attempts to advance in open formation were easily checked.

The importance of the defence at the Passo di Buole can hardly be over-estimated. If the Zugna ridge had fallen, the effect upon the Pasubio position, already a salient, would have been more than serious, and upon the holding of the Pasubio lines depended the maintenance of the positions held by the right wing of the V. Corps. On May 22, following upon the retreat from the Campomolon line, the troops holding the lines in the Seven Communes had been detached from the V. Corps, and the command in this sector had been given to Gen. Lequio, who had come from Carnia. On May 24 the rest of the V. Corps had for the most part retired beyond the Posina or down the Astico to the plain, and had been replaced by the 27th Division. If Pasubio went, the line south of the Posina was turned, and the Austrians had a new route to the plain by the Valli dei Signori, as well as the opening they were now making for, by the Lower Astico. Pasubio was the key of the situation, and the Austrians hammered unceasingly against Bertotti's right wing. The guns never ceased, and a long succession of attacks broke in vain upon the Italian lines. The Austrian infantry advanced along the great ridge from Col

Santa; they came up from Anghebani and Chiesa in the Vallarsa and from the Val Terragnolo by the Borcola Pass. Bertotti had four brigades under his command, including the remains of the Roma, and the 6th Group of Alpini, and he changed his troops continuously. The conditions were very hard, and frostbite was responsible for many casualties, for the snow still lay deep on the high ridges, but the spirit of the troops was proof against all trials, and it was against the iron lines of Pasubio that the Austrian offensive came to failure.

North-east of Pasubio, along all the rest of the mountain front to above the Val Sugana, the Austrians gained notable successes. The gap between the 35th and 34th Divs. had been filled by the arrival of the 30th Div. (XIV. Corps), and the 28th was on its way, the three Divs. (34th, 30th and 28th) now forming the XIV. Corps under Lequio. But von Koevess's attack had broken through the Italian line in the Seven Communes. For two days the Italian 34th Div. had fought off the attacks of the Graz (III.) Army Corps. On May 21 the order was given to retire to the line Monte Verena–Cima di Campolongo, and the stay on this line was short. Contact was lost with the left wing of the XVIII. Corps in the Val Sugana, and the Austrians turned the right wing of the division by a bold and skilful advance by way of the Porta Manazzo. A retreat was ordered to the Portule line, east of the Val d'Assa, which was supposed to be the principal line of resistance. The 34th was unable to stand on this line. Owing to an error in the transmission of an order the Alpine troops who were holding the positions of Cima Undici and Cima Dodici retired before the Austrians attacked, and uncovered the flank of the division, while on the same day (May 25) the attacking forces succeeded in occupying the important position of Corno di Campo Verde (6,815 ft.). Next day the attack was continued from north and west, and the Italians were swept off the whole line between the Val d'Assa and the Val Galmarara. A number of prisoners and guns were lost, and prospects looked black for the Italians, though the 28th Div. was now coming into action. On May 26 the situation was such that Cadorna thought it wise to make further preparations for a step which he had already considered and planned—a retreat from the Isonzo and Cadoro. He ordered all heavy artillery not absolutely necessary for defensive purposes, and all stores beyond the minimum required for immediate supplies, to be withdrawn from the Isonzo front and brought south of Treviso, behind the Silo. With the possibility of a general retreat in view, it seemed necessary to withdraw the heaviest impedimenta in good time. Although Cadorna believed that he could hold back the Austrian attack, he had no intention of omitting any precautions.

The Italian position looked unfavourable and worse was yet to come, but Cadorna's confidence was justified. The impetus of the Austrian attack was dwindling. The effort had been great, and losses had been very heavy. The attacking divisions were beginning to lose their offensive value, and the reserves were insufficient. By May 27 Conrad had been compelled to ask Falkenhayn to send to Italy a division of the Austrian XII. Corps, which belonged to Prince Leopold's Army Group. By the end of the month Cadorna was holding his own, although both Dankl and von Koevess were still making progress.

On May 27 Dankl's left wing was down in the Astico valley and close upon Arsiero, and on the following day his centre crossed the Posina in force and attacked the Italian 27th Div. on the southern slopes of the valley. Stiff fighting took place beneath Soglio di Campiglia and Pria Forà, and the Italians withdrew to the mountain line which had been hastily prepared from Forni Alti by Monte Spin to Pria Forà. Retiring on the night of May 29, the troops that were to fall back upon Pria Forà lost their way in the dark and kept too far south, halting on Monte Ciove, the ridge that joins Pria Forà to Monte Novegno and Monte Brazome. At dawn the mistake was realized, but the quick-following enemy were already in possession of Pria Forà, which is almost impregnable from the south. A desperate attack failed to retrieve the error, and Pria Forà remained in possession of the Austrians.

The line now held by the Italians (27th and 9th Divs.) was the last bulwark defending the plains in this sector, and both here and across the Astico the Austrians made a great effort to break through. The bulk of the 30th Div. was slowly pushed back across the Val Canaglia, in spite of a prolonged and gallant resistance by the Grenadier Bde. on Monte Cengio. Although the Grenadiers finally lost the summit of Cengio, they held on to the lower slopes above Schiri, and Dankl was unable to make headway in the valley, while the right of the division was swung back to the western slopes of Monte Pau. For a long fortnight Dankl hammered at the line south of the Posina and east of the Val Canaglia, but could not gain a yard. On June 1 the 27th Div. front was reduced, the remade 35th Div. under Gen. Petitti di Roreto coming into line in the Novegno sector, and the 9th (Gen. Gonzaga) taking both sides of the Astico valley. Dankl's attack was specially directed against two points: Monte Pasubio, where troops of the VIII. and XV. Corps were thrown again and again to the attack, and the Novegno sector, where the Archduke Charles concentrated his main effort against Petitti's troops. The attack was bound to follow this direction. It has been suggested that the Archduke should have pushed straight for the plain, down the Lower Astico valley. If ground had been gained here it would have been useless. The weak point of the Austrian position was that their successes were gained on a constantly narrowing front. The wings of the Italian line had held firm, and it was above all necessary to gain room south of Arsiero. On June 2, 3, 4 and 5 massed infantry attacks were delivered south of the Posina, but no impression was made on the Italian lines.

Meanwhile von Koevess had been pushing back the Italians in the Seven Communes. On May 28 Asiago was evacuated, and farther north the 34th Div. retreated from east of the Galmarara across the parallel valleys of Nos and Campomulo. Farther north again the Austrians gained ground on the Marcesina plateau and so came within 4 m. of Primolane in the Val Sugana, a point well behind the Italian lines in the valley. But communications were nearly impossible here, and von Koevess had to make his effort more to the south, narrowing still further the front of attack. An endeavour to gain ground in the Val Sugana had failed on May 26, and no other attempt was made in this sector, for which, in fact, there were no more troops available.

By June 2 Cadorna's V. Army was assembled in the Vicentine plain, and on June 4 Brusiloff broke through at Lutsk. The first news of the Russian attack did not perturb Austrian headquarters, though Gen. von Cramon was taken aback. Conrad thought that his line in the east was firmly held. In a few days the situation was changed altogether. But even before the news of the disaster had reached Bozen it was clear that the offensive against Italy had failed. Von Koevess was to gain a little more ground. After four days' heavy fighting east of the Campomulo valley and towards the head of the Val Frenzela, on the evening of June 8 the Italian right on Monte Castelgomberto was forced to retire from the summit of the mountain, but no ground was lost towards the Val Frenzela. The Austrians were only 3 m. from Valstagna, low down in the Brenta valley, but they had shot their bolt.

In spite of the news from the Russian front the attack was continued, south of Asiago and south of the Posina, for 10 more days. Here were the shortest routes to the plain, and here the Austrians had been able to bring up their guns in sufficient numbers. The Archduke Charles continued his attacks against Petitti's division, and Kirchbach's I. Corps made a great effort against the Italian positions south-west of Asiago. With the arrival of reënforcements the Italian line was once more rearranged, Gonzaga's 9th Div. passing to the X. Corps command (Gen. Grandi), the second division of the Corps (the 20th) lying in reserve, while the XXIV. Corps (Gen. Secco) came in between the X. and the XIV., its front-line division (the 32nd) taking over the gallant Grenadier Bde., which had suffered very severely in the Cengio and Val Canaglia fighting, and the 33rd being held in second line till June 7, when it replaced the 32nd.

The command of the 30th Div. received two fresh brigades, Forli and Piemonte, on June 7, after a furious attack which gave the Austrians a footing on Monte Lemerle, and for 10 days the division fought off repeated infantry attacks. On June 15 the Austrian command issued an army order saying that Monte Lemerle would fall in two days, and that only three mountains blocked the way to Milan. For four days the Austrians attacked, making a last effort on June 18, when 20 battalions were sent in against the Lemerle–Magnaboschi line in an attempt to drive a wedge between the Italian 30th and 33rd Divisions. The attack failed completely, thanks to the heroic defence of the Forli Bde., and the admirable work of the Italian field guns. To the east of the Val Canaglia the result was the same, the Liguria Bde. of the 33rd Div. holding their ground against repeated infantry attacks, backed by greatly superior artillery fire. Weakness in artillery was Cadorna's main preoccupation for many days. In the early stages of the offensive the I. Army had lost over 400 guns, including over 120 heavy and medium calibre. The first reënforcements had to be sent to strengthen the left wing. The next urgent need was north of Asiago, where the 34th Div. was reënforced by guns sent up by Enego, and in the Lower Astico, to stop the Archduke Charles. The troops between Asiago and the Val Canaglia had very few guns, and even when sufficient artillery reënforcements were available Cadorna preferred first to strengthen his wings for the counter-attack that he was already preparing.

The Archduke Charles made his last infantry attack on June 14, at the close of three days' heavy fighting for Monte Ciove, in which the Cagliari Bde. withstood repeated attempts to break through at this vital point. The rest of the division was equally staunch, and the troops were helped by the example of their commander. Petitti had established his divisional command far forward on Monte Novegno, where it came under the heaviest shell-fire. All around the ground was pocked with shell-holes; several times telephonic communication was interrupted, so that orders had to be given by megaphone or bugle; on June 12 the majority of the divisional staff was put out of action by a direct hit. The command was obviously too far forward, but it was the knowledge of their general's presence, amid the same dangers as themselves, that kept the men firm in their places in spite of the long strain and terrible losses. The Cagliari Bde. lost two-thirds of its strength, and other units suffered nearly as heavily.

The last Austrian blow was struck on June 18, south of Monte Lemerle, in vain, when already the first move of the Italian counter-attack had taken place. Cadorna had declined to draw upon his new V. Army prematurely, as he wished to keep a "mass of manœuvre" in hand against the possibility of a break-through by the Austrians; but by June 2 he felt himself master of the situation. He had 12 divisions in the plain under Frugoni, and the attack was already slackening. The XXIV. Corps was detached from the V. Army and sent to the south of the Asiago plateau, as already described, and orders were given to the XX. Corps to concentrate north of the Val Frenzela and prepare to attack the Austrian left. The attack was not to be made until the position in the centre was assured, and it was to be accompanied by an advance from Pasubio upon Col Santo. On June 13 Cadorna took counsel with his generals, who were nearly unanimous in expressing a grave view of the situation. Bertotti was confident that he had the measure of his adversary in the Pasubio sector; the others felt themselves still hard pressed by the Archduke Charles and von Koevess's right wing. Cadorna had confidence in his own estimate of the situation, and confirmed the order for an attack by the XX. Corps, which came into action between the XIV. and the XVIII. The Alpine troops on the right of the Corps pushed forward quickly and occupied various important heights on the northern rim of the Asiago plateau. But the Austrians were now getting ready to go—out of the salient and back to a strong line which they had already selected.

Attacking on May 25, all along the line, the Italians found the invaders in retreat. In some places rear-guards were left to cover the withdrawal; in others the Italians, advancing cautiously, in some cases too cautiously, found no resistance until they had made considerable progress over the difficult ground. The counter-offensive, which was to be directed against the two sides of the Austrian salient, was never fully developed, for it was anticipated by the Austrians, who withdrew skilfully and in good order. The line chosen by Krauss ran from south of Rovereto in front of Col Santo to the Borcola Pass; thence along the rim of the Arsiero plateau, north of the Posina and east of the Upper Astico; thence north-eastward across the Val d'Assa to Monte Mosciagh, and thence northward to the old frontier. This gave a very strong defensive line, with ample depth east of the Upper Val d'Assa, which therefore remained entirely in Austrian hands, a useful line of communication in any case, and an invaluable opening in the event of further offensive action.

Cadorna was especially anxious to reach the Portule line, and he reënforced the troops in the Seven Communes (now under the command of Gen. Mambrotti, who had replaced Lequio) by four divisions of the V. Army, now available as a reserve on the understanding that they were not to be employed unless the situation should develop favourably. But the Austrians had a great advantage in position, and used it well. The Italian attacks, handicapped by the limitation imposed, made little headway, though they prevented the dispatch of Austrian units already under orders for the eastern front. Farther south, repeated attempts were made to retake Monte Cimone, which the Archduke Charles had wished to abandon, but which Krauss insisted should be held. Although Alpine troops gained a footing north of the summit they were subsequently blown off by a mine, and Monte Cimone, which rises sheer-sided, like a vast battleship, between the Astico and the Rio Freddo, completely dominating the Arsiero basin, remained in Austrian hands.

Cadorna relinquished the idea of a big counter-offensive as soon as he found a resistance which could only be overcome by long preparation and the use of artillery in mass. The fighting which took place after the first week in July was all directed to masking his intention to attack with all speed upon the Isonzo.

The Austrian attempt to break through ended in definite failure, and even its secondary object, that of preventing the Italian offensive on the Isonzo, was not attained. But the attack was well planned, and conducted with skill and determination. The Austrian artillery fire was very destructive; the transport was admirably organized, and worked very well in spite of the great difficulties of the *terrain;* the infantry, most of them picked troops, fought with high courage and determination. Failure was due to the fact that the attack met with a resistance that went beyond Conrad's calculations. In the first days of the attack some Italian units, badly placed and badly handled, showed only a feeble opposition. In the weeks that followed, the men who held at Passo di Buole and on Pasubio, south of the Posina and east of the Val Canaglia and in the Seven Communes, outnumbered at first and always outgunned, completely broke up the attack that had begun so well. The casualty list shows the nature of the fighting. The Austrian losses were estimated at over 100,000 men; the Italian figures, up to the end of the counter-movement, are: 35,000 killed and 75,000 wounded, with 45,000 prisoners, many of whom should be counted among the wounded.

The success of the Italian resistance was primarily due to the power of the Italian soldier, when properly handled, to take hard punishment. It has already been said that in the initial phase of the battle the Italian leadership was at fault, and on this point much controversy has taken place, one party blaming Cadorna and another Brusati. In view of the facts and figures it seems impossible to avoid the conclusion that the chief responsibility lay with Brusati. On his own showing he had forces that he considered sufficient, and perhaps they might have been if they had been more skilfully disposed. Brusati had failed to realize the necessity of defence in depth, or the essentials of a good defensive line, but a graver error still was

his neglect in regard to the preparation of second-line positions. It was serious enough that the positions indicated by Cadorna in the early days of the war had not been prepared. Much more serious was Brusati's report that these lines were in a satisfactory state of efficiency, when in fact they were largely untouched. Cadorna relied upon Brusati's reports, and when, at the end of April, he inspected the positions himself, the enemy attack was daily expected, and it was too late to effect more than slight modifications. In reply to the common criticism that Cadorna ought to have inspected the lines earlier, the answer is that he was fully occupied from Oct. to Dec. 1915 with his Isonzo offensive, and that from Dec. to April the greater part of the line between the Val Lagarina and the Val Sugana was under deep snow. After the initial disasters, which can scarcely be laid at his door, Cadorna showed the qualities of a great leader. He was quick to grasp the situation, and effective in the measures he took to cope with it. And he realized, when the outlook seemed blackest and all his generals were against him, that the impetus of the enemy attack was failing and that he could control the situation.

It has been suggested that Cadorna should have pursued his counter-offensive and left the Isonzo alone. There will always be adherents of the fallacy that Italy should have attacked through the Trentino, though they are in the main confined to those who do not know the country, or those who have no experience of modern war. With these, presumably, no argument would serve. To those who maintain that Cadorna should have sacrificed everything in order to improve his defensive position in the Trentino sector, it may be answered that the line on which he stopped (or rather the modification of it necessitated by the retreat after Caporetto), properly prepared, backed by other lines in sufficient depth, and adequately served by new roads, was maintained until the end of the war. In refusing to waste men in attempting more than was necessary Cadorna took the right decision, and won a notable success.

(W. K. McC.)

ASIA MINOR (*see* 2.757).—With the Turkish revolution in 1908 and the Armenian massacres of the following year began a series of radical changes in the political division of Asia Minor; nor was it yet possible in the summer of 1921 to foresee the end. In the Italo-Turkish and Balkan wars of 1911–3 the Ottoman Empire lost islands on the coast of Asia Minor. The World War of 1914–21 saw the end of the empire itself, and the substitution of a Turkish state confined almost wholly to Asia Minor. The occupation of considerable territory by Greece in the region of Smyrna became effective, and at the same time the Turkish Nationalist Government with its capital in Anatolia offered successful armed resistance to the full execution of the Treaty of Sèvres. These events were accompanied by further Armenian massacres on the greatest scale. Asia Minor as a geographical entity was therefore in 1921 in no sense any longer a political unit.

ASKWITH, GEORGE RANKEN ASKWITH, 1st Baron (1861–), English lawyer and civil servant, was born at Morley, Yorks, Feb. 17 1861, and was educated at Marlborough and Brasenose College, Oxford. He was called to the bar in 1886 (K.C. 1908), and in 1899 was one of the counsel in the Venezuelan arbitration case. In 1907 he entered the railways section of the Board of Trade as assistant secretary, and in 1909 was appointed comptroller-general of the Commercial, Labour and Statistical Departments of the Board of Trade. He acted as arbitrator in many industrial disputes, and in 1911 was created K.C.B. in recognition of his valuable work in that capacity. In 1911 he became chairman of the recently constituted Industrial Council, in 1912 he made a special report for the Government on the Canadian labour laws, and in 1915 was appointed chairman of the Government Arbitration Committee under the Munitions of War Acts, holding this post till 1917. On the Committee of Production he did important work for the Government. In 1919 he retired from his position as chief industrial commissioner, and was raised to the peerage. His wife, whom he married in 1908, was a daughter of Archibald Peel, nephew of the statesman Sir Robert Peel, and the widow of Maj. Henry Graham (d. 1907). During the World War she was an active and energetic member of the Central Committee on Women's Employment, and was created C.B.E. in 1918.

ASQUITH, HERBERT HENRY (1852–), English statesman (*see* 2.769), had been confirmed in power as Prime Minister by the general election of Jan. 1910, but the political situation resulting from it was still one of unexampled difficulty (*see* English History). On several occasions during the ensuing parliamentary session, he put off importunate questioners, with regard to the policy of the Ministry, by saying that they had better "wait and see." The phrase was remembered, and was often used by critics in subsequent years, especially during the World War, as a compendious description of what they considered to be the procrastinating attitude of the Prime Minister and his Government. But there was no procrastination in Mr. Asquith's attitude in the autumn, as soon as the conference arranged between the opposing political leaders on the constitutional crisis had definitely failed. He and his Cabinet at once took decisive measures to get it settled in their own sense. On Nov. 15—the day Parliament reassembled for its autumn session —they advised the Crown to dissolve, but only on the understanding that "in the event of the policy of the Government being approved by an adequate majority in the new House of Commons His Majesty will be ready to exercise his constitutional powers, which may involve the prerogative of creating peers, if needed, to secure that effect shall be given to the decision of the country." The King reluctantly consented, and the dissolution was announced on Nov. 18; but the terms of the understanding which had been arrived at between the Crown and its advisers were not revealed till the crisis in the following summer. The second general election of 1910 was held in Dec.; and the verdict of the preceding Jan. was almost precisely confirmed.

Having, with the aid of Labour and the Nationalists, who were both thoroughly with him on the constitutional issue, a clear majority of about 120, the Prime Minister went straight ahead with the Parliament bill, which had two main objects: to take from the Lords all power of either rejecting or amending a Money bill, and to provide that a bill passed in three successive sessions by the Commons should become law without the Lords' assent. He carried the second reading in March with the closure, defeated the stubborn resistance of the Unionists in committee by aid of the "kangaroo" closure, and obtained the third reading on May 15 by an unbroken majority of 121. He did not conceal in the debate that the first use to which the new powers conferred by the bill on the Commons would be put was to pass the Irish Home Rule bill, followed by the rest of the controversial Liberal programme. When the Lords, after allowing the second reading to pass, introduced by an enormous majority an amendment (amongst others) providing for the submission to a popular vote of certain fundamental measures, he forthwith announced, in a letter to Mr. Balfour on the day (July 20) on which the amended bill was read a third time in the Lords, that the Government would ask the House of Commons to disagree with the amendments, adding:—

> In the circumstances, should the necessity arise, the Government will advise the King to exercise his prerogative to secure the passing into law of the bill in substantially the same form in which it left the House of Commons, and His Majesty has been pleased to signify that he will consider it his duty to accept and act on that advice.

This, the first public announcement of the King's consent to the creation of sufficient peers to pass the bill, produced an explosion among the Opposition; and the Unionist hotheads, among whom Lord Hugh Cecil and Mr. F. E. Smith (afterwards Lord Birkenhead) were conspicuous, shouted "Traitor" at Mr. Asquith in the House of Commons, and refused to let him deliver the speech in which he was to explain his policy. But he had effected his object of dividing the Unionist party; and eventually a sufficient number of peers followed their leaders in bowing to *force majeure* and allowing the bill to pass rather than risk the degradation of their House by an unlimited creation (*see* English History). Mr. Asquith welcomed the vote of censure which the Opposition promoted in the House of Commons; gave

an account of the understanding entered into with the King before the last dissolution; pointed out that the Parliament bill had been twice approved by the electorate in principle and once in its substantial details, that there was no alternative Government possible and no responsible minister at its head would advise another general election with any hope of a different result. The vote of censure was repelled by the usual Government majority; and, though Mr. Asquith's course had profoundly exasperated his opponents, the direct and unflinching manner in which he had carried his policy through raised his own parliamentary reputation and strengthened his Government.

Having cleared the way by the Parliament Act, which he described as "a landmark in political development," the Prime Minister pressed forward, by frequent use of the closure, in the three following sessions—of 1912, 1913, and 1914—the two bills on which Liberal partisans had specially set their heart, the Irish Home Rule bill, and the Welsh Disestablishment bill. Of the Home Rule bill he took the main charge himself, advocating it as being strictly in accordance with the spirit and tendency of imperial development. In July 1912 he went across to Dublin, and at a great Nationalist meeting in the Theatre Royal he described the intention of the Government to be to unite the English and Irish democracies. While speaking as a rule respectfully of Ulster, and offering to strengthen the safeguards for her welfare contained in the bill, he resolutely refused, till the autumn of 1913, to consider the possibility of her exclusion even for a time. But after the signing of the Ulster covenant, the enrolment and drilling of thousands of volunteers, and the establishment by Sir Edward Carson of a "provisional Government"—with none of which operations did he think it wise to interfere—he realized that, unless Ulster were placated, the new Home Rule constitution could not be set up without something like civil war. Accordingly, at Ladybank, in Oct. 1913, he said that he desired a settlement by consent, and invited a frank interchange of views; but he stipulated that there must be a subordinate Irish Parliament and an executive responsible to it in Dublin, and that no insuperable bar must be erected to Irish unity. In pursuance of this policy, he announced early in the following March, when moving for the third time the second reading of the Home Rule bill, that the Government would propose that any county in Ulster might vote itself out of the bill for a period of six years. This did not at all satisfy the Unionists, who demanded that Ulster should be omitted till Parliament otherwise ordered. At this moment occurred the incident at the Curragh, where military officers, when questioned on their views, offered their resignations rather than undertake military operations against Ulster. The War Office prevailed on them to withdraw their resignations by an assurance that there was no intention of crushing political opposition to Home Rule; a kind of bargain which the Liberal party and the Liberal press vehemently condemned and the Government itself repudiated. General Seely, the War Minister, immediately resigned, and Mr. Asquith met this situation by himself assuming the seals of the Secretary of State. He laid it down that it was not right to ask an officer what he would do in a remote and hypothetical contingency, still less could it be right for an officer to ask a Government to give him auy assurance. Such a claim, once admitted, would put the Government and Parliament at the mercy of the military. He would administer the War Office, he told his constituents, in the spirit of Chatham, who said, "The army will hear nothing of politics from me, and in return I expect to hear nothing of politics from the army." These events raised passions on both sides, but the Prime Minister refused to be moved from his offer. The amending bill was introduced in the Lords, but was transformed by Unionist amendments into one for the permanent exclusion of Ulster—a change which the Government refused to accept. Mr. Asquith then, in a final effort for settlement by consent, risked his popularity with Radicals and Labour men by advising the King to invite the leaders of the English and Irish parties to a small conference at Buckingham Palace. When this conference, too, after a four days' session, failed on July 24, he was relieved of his difficulty as to the next step by the outbreak of the World War.

In no other domestic measures of his Government during this period had Mr. Asquith taken so prominent and personal a part as in the Parliament Act and the Home Rule bill. But he was, of course, mainly responsible for the drastic use of the closure, in various forms, without which, indeed, it might have been impossible to get the most contentious of the Government bills through at all. He was active in efforts, first to avert, and then to compose the great coal strike of the early spring of 1912. From the third week in Feb. till the middle of March he was in constant conference with both owners and miners; and when conciliation failed he finally introduced and passed a Coal-mines (minimum wage) bill, which brought about a settlement at Easter. With the transport strike in the summer of 1912 he declined to interfere. His various franchise bills came to naught owing to the difficulties introduced by the claim of a large body of women to the suffrage. Though he was prepared to leave that thorny question to be decided freely by the House, he was himself, unlike the majority of his colleagues, opposed to giving women the vote, and was, accordingly, in the last few years before the war, frequently subjected to rudeness and insult by the militant section of suffragists. While in the domestic legislation which he promoted, especially after he was compelled by his own party's electoral losses in 1910 to rely largely on Nationalist and Labour votes, Mr. Asquith leaned to the Radical side, in foreign and imperial policy and in matters of defence he acted up to the Liberal Imperialist principles of which he had been the standard-bearer while in opposition. He took a keen interest in his duties as chairman of the Committee of Imperial Defence; he strongly supported Lord Haldane in his efforts to make the army more efficient as a striking force; he steadily backed first Mr. McKenna, and afterwards Mr. Churchill, in their extensive programmes, which increased the navy estimates from some £32,000,000 in 1908 to nearly £52,000,000 in 1914; he was the first Prime Minister to preside in a colonial, now become an imperial, conference; and while, owing to his Free-Trade principles, he rejected colonial or imperial preference, he pushed forward organized schemes for imperial defence. The experience of the World War, however, seemed to show that he made a mistake in accepting the Declaration of London. In foreign affairs he gave consistent and strenuous support to Sir Edward Grey, who had continued to develop the national policy previously laid down hy Mr. Balfour and Lord Lansdowne. This was fully recognized by the Opposition, who supported him on these questions against the sporadic attacks of Radicals, Nationalists, and Labour men. Whenever Mr. Asquith had to speak to the world as the nation's mouthpiece, in Parliament or at Guildhall, he produced a weighty impression by his clearness and candour in statement, and his dignified and sonorous phraseology.

When the world crisis came in the end of July 1914, he had to translate speech into action, with a hesitating Cabinet, and a still more hesitating party, behind him. He, like Sir Edward Grey, had been lulled into comparative optimism by the speciously reasonable attitude of Germany in the Balkan negotiations; and he was confronted by a strong section in the Cabinet, including Mr. Lloyd George, who at first refused to see cause, in the threat to France, for British armed intervention. On the other hand, he had the tender of support from the Unionists in continuation of their foreign policy since 1905. In the end, the violation of Luxemburg and Belgium by Germany solved all his difficulties, and enabled him to preserve his Cabinet intact save for the perhaps inevitable resignations of Lord Morley and Mr. Burns; but even before this happened it was becoming clear that he and Sir Edward Grey would take their stand by the side of France. His public language was eminently worthy of the occasion. On July 30 he told the House of Commons that the Amending bill must be postponed. The issues of peace and war, he said, were hanging in the balance; it was of vital importance that Great Britain, who had no direct interests at stake, should present a united front, and speak and act with the authority of an undivided nation. He left to the Foreign Secretary the duty of explaining the diplomatic position on Monday Aug. 3; but

he himself moved, on Aug. 5, the day after war had begun, the first vote of credit for £100,000,000, maintaining that "the war has been forced upon us." The fight was, first, to fulfil a solemn international obligation; secondly, to vindicate the principle that small nationalities were not to be crushed, in defiance of international good faith, by the arbitrary will of a strong and overmastering power. No nation, he said, ever entered into a great struggle with a clearer conscience and a stronger conviction that it was fighting for principles vital to the civilized world.

In response to a public demand, peremptorily voiced in the press, he now brought Lord Kitchener, who was on the point of starting back, after a brief visit home, to resume his duties as British agent in Egypt, into the Cabinet as Minister of War, surrendering to him the seals which he had held himself for over four months, and he gave him a wide discretion in conducting the war by land. The conduct of the war remained ultimately with the Cabinet, but its day-to-day direction was practically carried on by Mr. Asquith, Lord Kitchener, and Mr. Churchill, with the assistance of their technical advisers. As Prime Minister, too, Mr. Asquith must be accorded his full share in the important measures taken by the Cabinet at this time, such as the financial moratorium, the prompt despatch of the expeditionary force, the enrolment of Kitchener's army, the glad acceptance of colonial help, the decision to bring over native troops from India, and the Defence of the Realm Act. He, however, strained his relations with the Unionists by determining to pass the Home Rule and Welsh Disestablishment bills under the Parliament Act, only providing that neither should come into effect till after the war, and that special provision should be made for Ulster, which should in no circumstances be coerced. He undertook a series of speeches in the autumn, notable alike for patriotic vigour and for lofty eloquence, in order to educate the nation as regards the objects and necessity of the war, and to stimulate recruiting. At the Guildhall on Sept. 4 he said that this was not merely a material but a spiritual conflict, and recalled how England had in the Napoleonic Wars responded to Pitt's dying appeal to her to save Europe by her example. At Edinburgh, on Sept. 18, he said that the German creed of material force was a purblind philosophy, and that, while the British task might take months or years, the economic, monetary, and military and naval position was encouraging. At Dublin, on Sept. 25, he appealed to Ireland to take her due share in a war which was being fought in the interests of small nations. At Cardiff, on Oct. 2, he revealed the fact that, in 1912, the Cabinet had formally notified the German Government that Great Britain would "neither make nor join in any unprovoked attack on Germany," but that Germany had demanded in response a British pledge of absolute neutrality if she were engaged in war—a pledge which, of course, Britain could not possibly give. He finished up this series of orations by a resolute speech at Guildhall on Lord Mayor's day; when he told the city that it would be a long-drawn-out struggle, but that England would not sheathe the sword until Belgium had recovered all and more than all that she had sacrificed, until France was adequately secured against the menace of aggression, until the rights of the smaller nationalities were placed on an unassailable foundation, until the military dominion of Prussia was fully and finally destroyed. On Nov. 25 he formed a war council, consisting of the Chancellor of the Exchequer, the Foreign Secretary, the Indian Secretary and Lord Haldane, in addition to Lord Kitchener, Mr. Churchill, and himself; but the main responsibility still rested on the last three, and the naval and military experts attended in a somewhat undefined position.

As the fervour of the early months of the war died away, many troublesome questions embarrassed Mr. Asquith and his Government. Besides the anxious problem of the Dardanelles expedition, he had to consider whether the system of compulsory service, hateful to the traditions of the Liberal party, had not become inevitable; how to eradicate spying, and to what extent to intern aliens; how to deal with the problem of the liquor trade and traffic, which seriously interfered with necessary production; how to prevent the occurrence during war of industrial disputes, which frequently broke out in the first half of 1915. Drink and strikes had a close bearing on the problem which became specially urgent in April, the absolute necessity of an enormous increase in munitions of war. *The Times* revealed the perilous shortage at the front; Mr. Lloyd George dilated upon it in the House; but Mr. Asquith, in a speech at Newcastle-on-Tyne on April 30, which was mainly devoted to emphasizing the importance of *matériel* in this war and to encouraging miners, shipbuilders, engineers, iron workers, and dockers to further efforts, raised a storm of criticism by denying that the operations in the field had been crippled because of a want of ammunition.

The uneasiness in the country immediately increased, and there was a pronounced demand for broadening the basis of Government. On May 12 Mr. Asquith repudiated the idea that any such step was in contemplation; but a week later, the quarrel which had developed between Mr. Churchill and Lord Fisher at the Admiralty convinced him that there must be a change, and he invited the Unionists, the Labour party, and the leaders of the two Irish parties to join him in office, by forming a Coalition Ministry. From all whom he invited, but Mr. Redmond, he received acceptances, and he was able to find places in his new Cabinet for them without excluding any important previous colleague of his own, except Lord Haldane, whose German affinities had offended public opinion. He gained the services of many powerful men among the Unionists—Mr. Bonar Law, Lord Lansdowne, Mr. Balfour, Lord Curzon, Mr. Chamberlain, Mr. Long, Mr. F. E. Smith, Lord Robert Cecil, Lord Selborne; of Mr. Henderson and Mr. Brace from the Labour party; and of Sir Edward Carson, the Ulster leader. But he kept the premiership in his own hands, and retained Sir Edward Grey at the Foreign Office, and Lord Kitchener at the War Office. He explained his decision in the House of Commons in these words:—

> What I came to think was needed, was such a broadening of the basis of the Government as would take away from it even the semblance of a one-sided or party character, and would demonstrate beyond the possibility of doubt, not only to our own people but to the whole world, that after nearly a year of war, with all its fluctuations and vicissitudes, the British people were more resolute than ever, with one heart and one purpose, to obliterate all distinctions and unite every personal and political as well as every moral and material force in the prosecution of their cause.

He emphasized the facts (1) that in the Coalition no surrender was implied of convictions on either side; (2) that there was no change in national policy, which was "to pursue this war at any cost to a victorious issue." His Coalition Government made a good start. He constituted a new Ministry of Munitions, presided over by Mr. Lloyd George, who had by this time impressed the public as being the most resolute and determined of his colleagues; he and his Cabinet issued a great war loan; they introduced a measure for national registration; they imposed an enormously increased taxation; and there was established in the Cabinet a system of pooling salaries, so that every minister should receive the same amount. In June Mr. Asquith paid a four days' visit to the British front in France; and in July he attended a conference at Calais in which British statesmen and generals met French statesmen and generals in order to coördinate Allied action—the first of many conferences of the kind. On the adjournment of Parliament on July 28 he said that the war had become a struggle of endurance.

The formation of the Coalition did not stem the agitation for compulsory service; and in the autumn Mr. Asquith's Government appointed Lord Derby director of recruiting, in the hope that his energy would produce such satisfactory results as to obviate the necessity of resorting to compulsion. But Mr. Asquith stated that, if Lord Derby failed to bring in sufficient single men, he would come to the House without any hesitation and recommend some form of legal obligation. Lord Derby had a considerable but not an adequate success; and Mr. Asquith was driven to introduce compulsion in 1916, at first in a somewhat modified form, but later as universally applicable to males between the ages of 18 and 41. These measures caused the resignation of Sir John Simon, the Home Secretary. This

was the third loss of a colleague which the Prime Minister had suffered since the Coalition. Sir Edward Carson, the Attorney-General, had resigned in the autumn owing to the muddles of ministerial policy in the Balkans, and Mr. Churchill because of his exclusion from the immediate direction of the war. All three became occasionally keen critics of their former colleagues, whose delays in this vital matter of universal service weakened and discredited them in the country.

Mr. Asquith took a further step early in 1916 in the direction of close coöperation between the Allies by attending, along with Sir E. Grey, Mr. Lloyd George, Lord Kitchener and Gen. Sir William Robertson, an Allied conference in Paris, representative not only of England and France, but of Russia, Italy, Japan, Belgium, Serbia, and Portugal. Thence he went on to Rome, where he visited the Pope, and made a speech in the Capitol declaring the solidarity of Italy, France, and England at that critical moment of the world's history; afterwards proceeding to the Italian headquarters, where he was received by King Victor Emanuel and Gen. Cadorna. Later, in June, he and his Government arranged an economic conference, also in Paris, which provided for measures of economic union between the Allies, for conservation of the national resources of Allied countries, and for economic protection against enemy trade "penetration" and "dumping" after the war. His special attention was claimed at the end of April by rebellion in Ireland, the most serious incident of which was the capture of a great part of Dublin for a week by rebels (see IRELAND). After the suppression of the rising by the troops and the prompt execution of the leaders, he appointed a commission of inquiry, and he himself visited Ireland and returned with a conviction that a united effort must be made to reconstitute Irish government. He appointed Mr. Lloyd George to negotiate and formulate suggestions. In the result he proposed a provisional settlement, for the war and 12 months after, on the basis of bringing the Home Rule Act with certain amendments into immediate operation, with the exclusion of six Ulster counties. To this Sir Edward Carson agreed, but Mr. Redmond objected to the amendments, and nothing was done. The negotiations lost Mr. Asquith the services of Lord Selborne as the rebellion had deprived him of those of Mr. Birrell, the Chief Secretary for Ireland.

The basis of his ministry was rudely shaken in the summer of 1916 by the loss of Lord Kitchener at sea. Lord Kitchener's place at the War Office was taken by Mr. Lloyd George, whose reputation for "getting things done" had been enormously enhanced by the energy with which he had organized the Ministry of Munitions. The attack on the Somme seemed to promise an end to the trench war, but after many weeks of most determined fighting the German line was not broken through; and in the latter part of the year Rumania was crushed. These events increased public dissatisfaction, which had been stimulated by half-hearted dealings with the blockade of Germany, with the food problem, and with the creation of an adequate aerial force; and public criticism was focused on Mr. Asquith, whose incautious phrase of six years before—"wait and see"—was frequently flung in his face. In the House of Commons two strong committees, one of Liberals and one of Conservatives, had been formed for the purpose of the resolute prosecution of the war and the keeping of ministers up to the mark. Mr. Asquith's speeches were always resolute enough; he promptly denounced any overtures of pacifists for a premature peace; but he was thought to be lacking in initiative, and to carry into the counsels of war somewhat the attitude of an impartial Cabinet chairman weighing pros and cons and counting heads for a decision.

The War Council initiated under his Liberal Government was continued with very little modification, save in personnel, under the Coalition; and the final authority remained with the Cabinet. It was felt that a small body, sitting daily, with power to act at once without reference, was essential for the proper conduct of the war. Mr. Lloyd George, the most active member of the War Council, by a letter on Dec. 1, demanded the establishment of such a body, with himself as one of its members, but without Mr. Asquith. He subsequently amended his proposal, giving Mr. Asquith a consultative membership and a power of veto. But it was clear that the effect must be to transfer the main conduct of the war from Mr. Asquith to Mr. Lloyd George. Mr. Asquith, who had consented to reconstruct his Government, refused Mr. Lloyd George's ultimatum; and on Dec. 5 Mr. Lloyd George resigned. Without him Mr. Asquith clearly could not carry on, and he himself resigned the same evening, being succeeded, after some complications, by Mr. Lloyd George. So ended a premiership which had lasted nearly nine years, and left an ineffaceable mark on English history. He carried into retirement his principal Liberal colleagues, including Lord Grey of Fallodon; and many tributes of regard and respect were paid him by the Unionists who had been his colleagues.

After his resignation Mr. Asquith took his seat on the front Opposition bench; but he disclaimed being in any sense a leader of Opposition, and affirmed that his one desire was to give the Government the benefit of whatever experience he had gained. He maintained this attitude throughout 1917, making resolute and helpful speeches in different parts of the country on behalf of the national war aims. In Parliament he rendered material assistance to the Ministerial Franchise bill; and he announced that the services of women during the war had converted him to female suffrage. In 1918 he became rather more critical, and in particular called parliamentary attention to a letter in which Gen. Sir Frederick Maurice, formerly Director of Military Operations, challenged the veracity of ministerial statements. He moved to refer the general's charges to a select committee of the House, but was beaten on a division by 293 votes to 106. This action, taken during the period of the alarming German advance, marked a definite cleavage with the Government, which was widened after the Armistice by the conditions under which the general election was held in December. Mr. Asquith and those of his colleagues who had not joined Mr. Lloyd George, together with a considerable section of Liberal members, declined to pledge their support to the Coalition Government, and desired to be returned as independent Liberals. As the electorate was resolved that those who had won the war should make the peace and begin the reconstruction of the country, he and the whole of his principal colleagues lost their seats, and only 28 of his followers in all were returned. He did not come back to Parliament till Feb. 1920, when he was elected at a by-election for Paisley. This time he appeared as the leader of the independent Liberal Opposition which had been temporarily led in his absence by Sir Donald Maclean; but his followers, though they had gained some seats since the general election, were still smaller in number in Parliament than the representatives of Labour. Possibly for that reason he was more active in the country than in Parliament, devoting himself to efforts for reviving the Liberal party. He maintained that the time was come to put an end to the Coalition and resume party Government. He attacked ministers for their departures from Free Trade, for their wasteful administration, and for their policy in Ireland. He strongly condemned reprisals in that island, and declared for Dominion Home Rule. For a time he seemed to be recovering his hold on the country; but in the last half of 1920 and in 1921 there was a setback. It was no help to his political position that Mrs. Asquith published in the autumn of 1920 a volume of very frank and indiscreet *Reminiscences*.

In 1918 Mr. Asquith himself published a volume of *Occasional Addresses*, delivered between the years 1893–1916, thus reminding the world that he was a worthy successor of a long line of scholarly and intellectual Prime Ministers, capable of treating with distinction and acceptance matters of the mind wholly unconnected with politics. The book contained, amongst others, Rectorial Addresses to the universities of Glasgow and Aberdeen, a Presidential Address to the Classical Association, and a dissertation on "biography" read before the Edinburgh Philosophical Institution. The universities of the country duly recognized the claims made upon them by his scholarship. Besides being elected to the rectorships, first of Glasgow and then of Aberdeen, he received honorary degrees from Oxford, Cambridge, Edinburgh, Glasgow, St. Andrews, Durham, Bristol and Leeds.

Mr. Asquith had four sons and a daughter by his first marriage, and a son and a daughter by his second marriage. His eldest son, RAYMOND ASQUITH (1878–1916), had a brilliant career at Oxford, where he was a scholar of Balliol, gained a first class both in classical moderations and in *lit. hum.*, won the Ireland, Craven, and Derby scholarships, was president of the Union, and was finally elected in 1902 to a fellowship at All Souls. He went to the bar, and acquired a considerable practice, but when the World War broke out he at once sought a commission and was killed in action in France as a lieutenant in the Grenadier Guards. He left a widow and three children. The third son, ARTHUR MELLAND ASQUITH (1883–), distinguished himself greatly in the war, becoming brigadier-general and D.S.O. In 1918 he was appointed controller of the Trench Warfare Department of the Ministry of Munitions, and in 1919 controller, Appointments Department, and member of council at the Ministry of Labour. The fourth son, CYRIL ASQUITH (1890–), followed his brother Raymond in his Oxford career. He was a scholar of Balliol, gained a first class both in classical moderations and in *lit. hum.*, won the Hertford, Ireland, Craven, and Eldon scholarships, and was elected fellow of Magdalen. The war came just at the close of his undergraduate life, and he served in the army before being called to the bar in 1920. Mr. Asquith's daughter by his first wife, VIOLET, married his private secretary, Sir Maurice Bonham-Carter; his daughter by his second wife, ELIZABETH, married Prince Antoine Bibesco, for 16 years a member of the Rumanian Legation in London, and in 1921 appointed Rumanian minister to the United States. (G. E. B.)

ASTOR, WILLIAM WALDORF ASTOR, 1ST VISCOUNT (1848–1919) [*see* 2.794], died at Brighton Oct. 18 1919. He was in 1916 raised to the peerage, and in 1917 was created a viscount.

His son, WILLIAM WALDORF ASTOR, 2ND VISCOUNT ASTOR, born in New York May 19 1879, was educated at Eton and New College, Oxford. In 1911 he successfully contested the Sutton division of Plymouth as a Unionist, but vacated his seat in 1919 on succeeding to his father's peerage. He was chairman of the Government Committee on tuberculosis and of the State Medical Research Committee. During the World War he was inspector of quartermaster-general services, and in 1918 became parliamentary secretary to the Prime Minister. In Jan. 1919 he was appointed parliamentary secretary to the Local Government Board, and retained the same position on the formation of the Ministry of Health in Aug. 1919. His wife, NANCY WITCHER ASTOR, born in Virginia May 19 1879, was the daughter of Chiswell Dabney Langhorne, of an old Virginian family. She married in 1897 Robert Gould Shaw, of Boston, from whom she obtained a divorce in 1903, and in 1906 married William Waldorf Astor, Jr. When her husband succeeded to the viscountcy, Lady Astor, who had taken much interest in the local affairs of her husband's former constituency in Plymouth, was adopted there as Coalition Unionist candidate for the vacant seat in Parliament. She was elected by a substantial majority Nov. 28 1919, thus becoming the first woman to sit in the House of Commons.

ASTRONOMY (*see* 2.800).—This article is intended to cover the principal advances made during 1910–21 in all the departments of astronomy (including astrophysics) with the exception of the more technical results of celestial spectroscopy. Those investigations have been selected for discussion which appear to have had most conspicuous influence on the general current of ideas.

I. OBSERVATIONAL ASTRONOMY

The Sun (*see* 26.85).—By means of the spectroheliograph it is possible to obtain photographs of the sun in light of a single wave-length; we thus obtain a picture of the distribution of the matter which emits this wave-length, or a negative of the matter which absorbs it. In practice either calcium or hydrogen light is used, since these elements furnish spectral lines sufficiently isolated to give good results. The emission of a particular line depends on favourable conditions of temperature and density, and these will vary with the level in the sun's atmosphere. Thus the function of the spectroheliograph is not so much to separate the distributions of particular elements as to isolate different levels in the sun's atmosphere, and provide separate photographs of what is occurring at each level.

The recent pictures obtained with this instrument are of great beauty, and reveal remarkable structure, which is entirely lost in the ordinary photographs which confuse all levels in a single blurred impression. The highest level is given by photographs taken in the red line of hydrogen $H\alpha$: these show feather-like clouds, whirling vortices, and long narrow black markings which are now known to belong to the red prominences seen projected on the disc. The vortices are of special interest because of their connexion with sunspots; in most cases a sunspot occupies the trough of each whirlpool or whirlwind. If the whirling matter is electrically charged it should act like a solenoid and produce a magnetic field of force; and this consideration led G. E. Hale (1) to test whether a magnetic field could be detected in sunspots. When light is emitted or absorbed in a magnetic field each spectral line is broken up into two or more components—the well-known Zeeman effect; in particular, for light travelling along the lines of force, the spectral line is replaced by two components circularly polarized in opposite directions. Applying the test for circular polarization clear evidence of the magnetic field in solar vortices was obtained. In general the field strength indicated in a sunspot is of the order 2,000 or 3,000 gausses. It is probably owing to the Zeeman effect that a large proportion of the lines observed in sunspots are observed to be slightly broadened.

An attempt to find a law governing the magnetic polarity of sunspots has not been very successful. On the earth, cyclones have a right-handed or left-handed rotation according to the hemisphere, but there is no such regularity on the sun. There is some evidence that the predominant magnetic polarity in each hemisphere became reversed after the sunspot minimum of 1912. It is surprising to find that there is not even a uniform connexion between the polarity of the spot and the direction of rotation of the whirlwind above it. One very general law is, however, recognized. It was pointed out by Carrington that sunspots very frequently occur in pairs, the line joining them being approximately parallel to the sun's equator; now in these pairs the two spots are found to have opposite polarity. Even when the spot group is more complex a similar bipolarity is generally observed; Hale estimates that in 90% of the spot groups the disturbed area exhibits this bipolar structure.

The detailed explanation of these phenomena is difficult. If the magnetic field is due to the whirling of electrically charged gases, strong electric fields should be present; but the attempt to detect electric fields by the Stark effect on the spectral lines has failed. It seems to be a general belief that the origin of the whole disturbance is a vortex filament below the surface, whose two ends come to the sun's surface near the front and rear of the spot group and give rise to the opposite polarities there.

The method of detection of magnetic fields by the Zeeman effect, has been extended by Hale (2) to a determination of the general magnetic field of the sun (*i.e.* apart from the exceptionally disturbed regions indicated by sunspots) analogous to the terrestrial magnetic field. It is found that the magnetic axis of the sun deviates from the rotation axis, though not so widely as happens on the earth; the inclination of the two axes is 6°. The synodic period of rotation of the magnetic axis is 31·44 days. If we could assume that the source of the sun's magnetic field is a permanent magnetization of its interior, this would give the real rotation period of the sun—a quantity hitherto unknown. Hitherto our study of the sun's rotation has been based entirely on the surface markings, and these revolve at different rates according to their latitude; the period 31·5 days corresponds to that of surface markings in latitude 55°. It may, however, be doubted whether the source of the sun's permanent field lies very deep below the surface; it is found that it diminishes very rapidly as we ascend in level, decreasing from 50 to 10 gausses in about 400 km. The field appears to differ in other respects from that due to a uniformly magnetized sphere, being relatively too strong near the equator; but this is not quite certain.

The value of the constant of solar radiation which is now generally accepted is that determined by C. G. Abbot, viz. that outside the earth's atmosphere the amount of solar energy crossing each sq. cm. of surface is 1·93 gram-calories per minute. This is the same as we should receive if the sun were a black body at a temperature of 5,850° C. (absolute), which may accordingly be taken as the effective temperature of the photosphere. (The definition of *effective temperature* by different writers is unfortunately not uniform; and some would make the term refer to the quality instead of the quantity of the radiation.) The total radiation of the sun is $3{\cdot}8 . 10^{33}$ ergs per second. The sun's radiant energy differs considerably in composition from black body radiation; and much work has been done on the distribution in wave length of the energy, and the difference in intensity and composition of light received from the centre and the edge of the sun's disc. By comparing observations of the solar radiation made simultaneously at Mount Wilson (California) and Bassour (Algeria) in 1911 and 1912, Abbot (3) believed he had obtained evidence of an irregular variability of the sun ranging over 10% in the course of a few months; since the same variations appeared simultaneously at the two widely separated stations, terrestrial causes

seemed to be excluded. But this supposed variability of the sun is disproved by Guthnieck and Prager's (4) photoelectric measurements of the brightness of the planet Saturn. The planet, being illuminated by sunlight, would reflect any changes in intensity of the sun's radiation; the delicate measures possible with photoelectric cells showed that the light is very steady, variations of the amount determined by Abbot being quite excluded.

Solar System (*see* 25.357).—A ninth satellite of Jupiter was discovered by S. B. Nicbolson at the Lick Observatory in 1914. Like the eigbth satellite it revolves round tbe planet in tbe opposite direction to the other seven. The periods of satellites VIII. and IX. are about 739 and 745 days respectively, and the two bodies are revolving in almost equal interlocked orbits in planes inclined at about 10°. Satellites VI. and VII. form a somewhat similar interlocked pair, their periods being 251 and 260 days respectively; but their motions are in the "direct" sense.

Much interest has been taken in the "Trojan Group" of minor planets. These illustrate a special case of the problem of three bodies discussed by Lagrange, viz. that in which tbe three bodies are situated at the vertices of an equilateral triangle. The Trojan planets have almost the same mean distance and revolution period as Jupiter, and the equilateral condition is roughly fulfilled. The problem of the small librations of such a planet about the triangular point of equilibrium has been discussed by E. W. Brown (5); the condition of stability is that the mass of Jupiter must be less than ·0385 times that of the sun —a condition which is easily satisfied—and the period of the libration is about 140 years. Actually the Trojan planets are at some considerable distance from the triangular points, and the problem of determining the finite librations (as opposed to infinitely small librations) has provided much exercise for mathematicians. Six members of the group are now known, Nos. 588 Achilles, 617 Patroclus, 624 Hector, 659 Nestor, 884 Priam, and 911 (unnamed); of these Patroclus and Priam are near the triangular point 60° behind Jupiter, and the others 60° ahead of Jupiter.

A very curious minor planet was discovered by W. Baade on Oct. 31 1920, temporarily designated 1920 HZ. Its orbit is extremely elliptical (eccentricity 0·65); and its perihelion lies near the orbit of Mars, whilst its aphelion reaches to near the orbit of Saturn. It is generally thought that a body with this eccentricity must necessarily be, or become, a comet, the extreme alternations of heat provoking the disruption characteristic of comets; but HZ shows no signs of a cometary envelope, and is provisionally classed as a planet.

The period of rotation of Uranus round its axis has been determined by V. M. Slipher from measures of the line of sight velocity of the advancing and receding limbs. The result is $10^h 50^m$ and the direction of rotation agrees with that of revolution of the satellites. Leon Campbell subsequently found that the light of the planet is variable with the same period, presumably owing to unequal brightness of different parts of the surface. The rotation period of Venus still remains a mystery; and there are advocates of the long period of 224 days as well as various estimates of short period (one to three days).

Latitude Variation (*see* 16.267).—The study of the small periodic motion of the eartb's axis of rotation (relatively to the eartb) whicb gives rise to "variation of latitude" has been continued at the six international stations (reduced in number during the later stages of the World War). The effect is made up of (*a*) The free precession of a spheroid rotating about an axis which does not coincide with its axis of figure; the period of this precession determined from the observations is 432½ days; (*b*) an annual term, which is a forced oscillation due to meteorological and seasonal causes. Owing to interference of these two terms, there is an effect analogous to "beats" in sound waves, the amplitude of tbe motion alternately rising to a maximum of about $0''\cdot3$ (30 ft.) and dying out in about six years' period. The annual term appears to be nearly circular (6) and of amplitude $0''\cdot085$; the possible causes contributory to this, such as seasonal circulation of the atmosphere and ocean, snowfall, and vegetation have been investigated by H. Jeffreys (7), who finds a fair agreement between predicted and observed values. A mysterious Kimura or *Z* term, which appears in these international results, would, if interpreted literally, indicate an annual approach to the pole and recession by all stations on the same latitude simultaneously—or a shifting of the earth's centre of gravity to and fro along its axis. It is, however, now believed tbat the term arises from a small systematic error in the observations; independent observations made at Greenwich and Pulkovo (not belonging to the international chain) show either a reduced or zero Kimura term.

The Stars (*see* 25.784).—Progress in our knowledge of the stellar universe must depend largely on tbe patient accumulation of accurate statistics as to the parallaxes, motions, spectra, magnitudes, etc., of large numbers of stars; it may therefore be well to review the great advance in these data in recent years.

The first pbotographic determinations of stellar parallaxes reaching a modern standard of accuracy were made by H. N. Russell and A. R. Hinks at Cambridge, and F. Schlesinger at Yerkes, in 1903–7; earlier results are now superseded except for a few of the best heliometer measures made cbiefly by Gill. Extensive programmes have since been carried out with large telescopes at the Allegheny, Greenwich, Leander McCormick, Mount Wilson and Sproul observatories, and by 1921 parallaxes of about 1,600 stars had been measured witb probable errors generally not greater than $0''\cdot01$. The use of a rotating sector to reduce the brightness of tbe star under observation to that of the comparison stars has made a considerable improvement in the accuracy. Unfortunately it does not follow that we know the distances of 1,600 stars, for many of these parallaxes turn out to be inappreciable. The results emphasize the fact that very few of the stars are sufficiently near for the method to give any close measure of the distance; and a large proportion of the measures are of little use individually though they may throw light on questions of statistical distribution when taken in conjunction with other evidence. We cannot resist the impression that investigation of stellar parallaxes by the trigonometrical method is reaching its limit with present instruments; and perhaps for that reason special interest is attached to a new method of determining the distances of stars described below under "Spectroscopic Parallaxes."

Lewis Boss's *Preliminary General Catalogue of 6,188 Stars* published in 1910 has been an invaluable aid to research with regard to proper motions. It comprises all the brighter stars, and the proper motions constitute a great improvement as regards both accidental and systematic error on anything previously available. Of other catalogues the most notable is the Greenwich 1910 catalogue containing the proper motions of 12,368 stars in the zone Decl.+24° to 32°; the accuracy, of course, does not equal that of Boss's catalogue, but it carries our knowledge of the motions of stars in this region as far as the ninth magnitude. We bave still very little systematic knowledge of the motions of still fainter stars, which can be measured photographically; attention has chiefly been directed to the detection of exceptionally large motions by the "blink" microscope or by other methods.

The first really extensive lists of radial velocities were published by the Lick Observatory in 1911. At present (1921) about 2,070 have been determined; these bave been collected in a catalogue by J. Voûte. Progress would have been more rapid but for the large proportion of spectroscopic binaries, which makes it necessary to repeat the measures several times at suitable intervals in order to discriminate between orbital motion and the true secular motion which is looked for. Orbits of 172 spectroscopic binaries are known; and in addition there are about 450 spectroscopic binaries witb orbits as yet undetermined. It appears therefore that approximately one-quarter of the stars examined have proved to be spectroscopic binaries. Allowing for systems of wider separation (not detected by varying radial velocity) the actual proportion of binaries must be still higher.

The apparent magnitudes of stars range from $-1^m\cdot5$ for Sirius, to 20^m and upwards for stars obtained by long exposures with the

largest instruments. The corresponding light ratio is more than 100,000,000 to 1; and it is an important and not very easy problem to subdivide this range accurately. For this purpose a set of 96 standard stars has been chosen near the North Pole, called the Harvard Polar Sequence; their magnitudes stretch at short intervals from the first to the twenty-first, and when once these have been accurately fixed on the absolute scale, it is comparatively easy to determine the magnitudes of any other stars by differential comparisons. There is some systematic difference between the standard magnitudes of the sequence adopted at Harvard and Mount Wilson respectively for part of the range, which is still being inquired into; but good progress has been made in establishing an accurate and absolute basis for magnitude determinations. Separate standards are needed for visual and photographic magnitudes; their relation has been fixed by international convention so that visual and photographic magnitudes agree for stars of type A0 between $5^{m}\cdot5$ and $6^{m}\cdot5$. Photographic magnitudes have been determined at numerous observatories, one of the most valuable pioneer investigations being K. Schwarzschild's *Göttingen Aktinometrie* of the brighter stars. Most of our data of visual magnitudes are due to Harvard (where the late E. C. Pickering alone made a million and a half photometric measures) and to Potsdam observatories. It is now becoming usual to determine "photo-visual" as equivalent to visual magnitudes, *i.e.* to use a photographic plate of colour-sensitivity corresponding to that of the eye.

Since the photographic plate is most sensitive to blue light and the eye to yellow light, the difference, photographic *minus* visual magnitude, gives a quantitative measure of the colour of the star. This is called the "colour-index." As might be expected, it is very approximately a function of the spectral type, so that the spectral type may generally be inferred from the colour-index and *vice versa.* This affords a very useful method of classifying stars too faint to permit of spectroscopic examination. The colour-index ranges from about $-0^{m}\cdot5$ for the bluest (type B) stars to $+1^{m}\cdot9$ for the reddest stars (type M). The Draper notation has almost displaced Secchi's and other early nomenclatures of spectral types. The principal stages from the hottest to the coolest are denoted by the letters B, A, F, G, K, M; and intermediate stages are estimated in tenths, *e.g.* "G5" means halfway from G0 to K0. Types B and A correspond to Secchi's type I.; F, G, K to type II.; and M to type III. Typical stars are B, Rigel; A, Sirius; F, Procyon; G, the Sun; K, Arcturus; M, Antares. In addition, the somewhat rare Wolf-Rayet stars form type O preceding and hotter than type B; and type N (Secchi's type IV.) appears to form an alternative branch succeeding K and parallel with M, the bifurcation perhaps depending on whether the star has an oxidizing or reducing atmosphere. More recently a type R, probably intermediate between K and N, has been added. In types M and N the temperature is low enough for the spectra of chemical compounds to appear prominently; type M is characterized especially by titanium oxide, and type N by compounds of carbon. A catalogue of the spectral types of 230,000 stars classified by Miss A. J. Cannon is in course of publication by the Harvard Observatory; about half of it has already appeared.

Giant and Dwarf Stars.—It will be realized that this great gain in quantity and quality of the material available for discussion has permitted of considerable advance in our knowledge of the structure of the stellar universe, since 1910. The most far-reaching of the recent discoveries is the detection of the two classes of "giant" and "dwarf" stars.

To understand this distinction we must go back to Homer Lane's theory of the evolution of gaseous masses (*see* 25.788). Starting with a very diffuse globe of gas held together by its own gravitational attraction, the conditions of equilibrium require that its temperature must rise when it contracts through radiation of heat. This rise of temperature continues so long as the material is rare enough to follow the laws of a gas; but as the density approaches that of a liquid the changed conditions limit the rise, and ultimately the temperature begins to fall again; the fall continues until the star finally becomes extinct. It follows that any particular temperature is passed through twice, once ascending in a comparatively early stage of evolution, and once descending in a later stage. Now the Draper and other standard classifications of stellar spectra are practically temperature classifications of stars; that is to say, temperature is the primary condition which determines the appearance of the lines and bands distinguishing the spectral types. So in any type of spectrum we have two groups of stars which agree in temperature but are wide apart in all other respects; more particularly they differ in diffuseness and stage of evolution. For example, the present effective temperature of the sun is 6,000°C.; it has a density greater than water and is accordingly in the dense descending stage; but at an earlier epoch it must have passed through the same temperature ascending. It was then a diffuse globe of about 10 times its present diameter and 100 times its present surface; the temperature of the surface being the same, it then gave 100 times as much light as now. These two stages are called the *dwarf* and *giant* stages respectively, and the most conspicuous outward characteristic is the great difference of luminosity, due to the larger surface area in the giant stage.

Instead of having a single sequence of evolution B, A, F, G, K, M we see that a star must start as a giant of type M, ascend the series towards type B, and then descend as a dwarf to type M again. It depends on the mass how far up the series it gets, and probably a star must be three or four times as massive as the sun in order to reach the high temperature of type B. Smaller stars will turn at A, F, or even lower. As Russell has put it, a star of small mass is a poor self-heating affair. The division of giants and dwarfs is most conspicuous for the lower temperatures, G, K, M, since the corresponding stages are then furthest apart in the evolutionary sequence; for types A and F the two groups begin to merge into one another, and the division is less easy to recognize.

These conclusions were put forward independently and simultaneously by H. N. Russell (8) and E. Hertzsprung. The observational evidence drawn from many sources is now overwhelmingly favourable. For stars of known parallax the absolute luminosity can be calculated directly; and when these are grouped according to spectral type the bifurcation of the luminosities is evident. The luminosities of the giant stars depend very little on the spectral type (since the rising temperature compensates for the decreasing surface area), and their absolute magnitudes cluster very closely about the value $+1^{m}\cdot0$.[1] For the dwarfs the decreasing temperature and decreasing surface cause a rapid fall of brightness through the successive types, and the absolute magnitude fades to about $+10^{m}\cdot0$ for type M. By the new spectroscopic method of determining stellar distances, Adams and Joy (9) have been able to give striking evidence of the two groups; of 58 stars of type M examined they found that 48 were giants with magnitudes between $-1^{m}\cdot0$ and $+3^{m}\cdot4$, and 10 were dwarfs between $+9^{m}\cdot8$ and $+10^{m}\cdot7$; there was thus a clear gap of six magnitudes separating the groups. Ascending to types K and G the groups draw closer together and begin to commingle, but even in type F the frequency curve shows the two distinct maxima. Further evidence is obtained from the study of eclipsing variable stars (10), since the average densities of these stars may be determined from the period and the light curve. For types B and A the densities are fairly uniform, averaging about one-tenth the density of water; but for lower temperatures they clearly bifurcate, the one branch corresponding to dense stars like the sun and the other to rarefied stars with densities often below that of our atmosphere. W. Crucis, R. Z. Ophiuchi and S. X. Cassiopeiae are examples of stars with densities less than 0·001, yet giving spectra classed as similar to that of the sun (density 1·38).

Finally all doubt as to the existence of these giant stars is set at rest by Pease and Anderson's direct measurement of the angular diameter of Betelgeuse made with a 20-ft. interferometer at Mount Wilson in December 1920. The angular diameter was found to be $0''\cdot045$. Unfortunately the parallax is too small to be measured with much certainty; but it may be taken as proved that it is less than $0''\cdot05$. This makes the linear diameter of Betelgeuse not less than 140 million km. or 100 times the sun's diameter. This is an example of a type M giant at the very beginning of the evolutionary sequence.

Spectroscopic Parallaxes.—Although giant and dwarf stars of the same temperature have, broadly speaking, the same spectrum, a detailed examination of particular lines reveals distinctive differences. It was early shown by E. Hertzsprung that those spectra marked by Miss Maury as having the "*c*-characteristic" belonged exclusively to giant stars. More precise criteria were found by W. S. Adams and A. Kohlschütter in 1914; and the method has been developed by Adams into a means not only of distinguishing the two classes but of determining quantitatively the absolute luminosities of stars. For example, the "enhanced lines" of strontium 4077 and 4215 are relatively strong in stars of high luminosity and weak in those of low luminosity; whereas the "furnace lines" of strontium 4607 and calcium 4455 behave in the reverse manner. Thus measures of the relative intensities of these lines give an indication of the luminosity of the star. In a general way we can understand the reason; enhanced lines come from ionized atoms, so that they appear when the conditions are favourable to ionization. Other conditions being equal, low density increases the ionization so that the enhanced lines are likely to be strengthened in stars of low density, *i.e.* the giants—as turns out to be the case. Considerable progress in the theory of ionization in stellar atmospheres has been made by M. N. Saha (11), the results being in good agreement with the observed conditions of emission of the corresponding spectral lines. But Adams's spectroscopic method of determining absolute luminosities (and hence parallaxes) is at present entirely empirical; that is to say, the curve connecting absolute magnitude with the differential intensity of the selected lines is first deduced from and tested by stars of known trigonometrical parallax; it is then applied to deduce the luminosities of other stars. Parallaxes determined by this method for 1,650 stars have already been announced (9).

Red Dwarf Stars.—Two very feebly luminous stars have been discovered which are of special interest owing to their closeness to us. In 1916 E. E. Barnard detected a star of visual magnitude $9^{m}\cdot7$ in

[1] The absolute magnitude is the magnitude at a distance of 10 parsecs. The parsec, or distance corresponding to a parallax of 1″, is $19\cdot2\times10^{12}$ miles. The absolute magnitude of the sun is very nearly $5^{m}\cdot0$; thus the zero of absolute magnitude is a star 100 times as bright as the sun.

R.A.17^h53^m, Dec. $4°27'$ N., having an annual proper motion of $10''.3$, the largest yet known. Its parallax is $0''.52$, which makes it the second nearest star (α Centauri being the nearest). A faint companion to α Centauri (sharing the same large proper motion) was discovered in the same year by R. T. A. Innes; its visual magnitude is $11^m.0$, and it has been verified that the parallax is practically the same as that of α Centauri. It appears that this companion is distant 10,000 astronomical units from the principal components, and its period of revolution round them must be a million years. It is now on the near side of its orbit so that it is actually the nearest star known; for that reason it has been named Proxima Centauri. Barnard's and Innes's stars, being both faint and close to us, must be of very low intrinsic luminosity; with them may be grouped two other companions to stars of large parallax, forming the four intrinsically faintest stars yet known:—

Barnard star	absolute visual magnitude	$13^M.3$
Proxima Centauri	absolute visual magnitude	15 ·4
Groombridge 34, *comes*	absolute visual magnitude	13
Pi. 2^h123, *comes*	absolute visual magnitude	12 ·3

As might be expected all four are red stars in the last stage before extinction, so that photographically their magnitudes are even fainter. Proxima gives less than 1/10,000 of the light of the sun. A distant companion to Capella discovered by Furuhjelm must also be very faint; but it is probably brighter than those above mentioned.

At the other end of the scale it is uncertain what is the maximum luminosity reached by the stars, because of the smallness of the parallaxes of those which are likely to be the brightest. Canopus, Rigel, and some others may approach or even surpass $-5^m.0$ (10,000 times the sun's luminosity), but it is not possible to obtain satisfactory evidence of anything brighter. The known range of absolute stellar magnitude is thus from $-5^m.0$ to $+15^m.0$, or a hundred-million-fold ratio of luminosity, with the sun just at the middle. This range is much the same as the known range of apparent brightness (in spite of the distance factor affecting the latter); so that apparent brightness is practically no guide to the distance. Stars of low luminosity are far more common in space than those of high luminosity. Thus we find the four red dwarfs above mentioned within a very small distance from the sun, and doubtless they are equally plentiful throughout the stellar system; but we have to extend our net to very great distances to catch Canopus and Rigel representing the most brilliant stars, and they ought to be regarded as very exceptional freaks of nature. Perhaps it is unfortunate that these exceptional stars catch our attention by their brilliancy, and figure to a disproportionate extent in our catalogues.

Masses of Stars.—In striking contrast to the enormous range of intrinsic brightness, is the comparative uniformity of the masses of stars. Some knowledge of their masses may be gained from a study of the orbits of visual binaries of known parallax, and also from spectroscopic binaries (in which case the parallax is not needed). In general the range of mass is surprisingly small, the result being usually between one-half and twice the sun's mass. Exceptions probably appear more numerous than they really are, because of our tendency to pick out the very luminous stars, which are believed to have masses above the average. Stars of type B are found to be on the average three or four times as massive as the others, confirming the view already mentioned that only a star of large mass can attain the highest temperatures. Both components of V. Puppis (type B1) have masses not less than 17 × sun[1]; these are the greatest yet measured, though we suspect that masses up to, say, 50 × sun may occasionally occur. The smallest mass known is that of the faint component of the double star Krueger 60 which is between 1/6 and 1/8 × sun. Attention to these extreme cases scarcely does justice to the uniformity of the great majority of the stars; from a theoretical relation between luminosity and mass for giant stars it is probable that 90% will have masses between ½ and 2 × sun.

Advantage is taken of this uniformity to determine the so-called "hypothetical parallaxes," or dynamical parallaxes, of double stars. If a is the semi-axis of the orbit in astronomical units, P the period in years, and m_1+m_2 the mass of the system in terms of the sun, we have

$$m_1+m_2=a^3/P^2$$

Thus a can be found if m_1+m_2 is known or guessed. We may assume with fair probability that $m_1+m_2=2$, the possible deviations being comparatively unimportant because the cube-root is taken in determining a. But the value of a in angular measure is found from the apparent orbit in the sky; comparing the angular measure with the linear measure given by the above calculation, we at once find the distance or parallax of the star. It is possible to modify the procedure so that it can be used when only a small arc of the orbit has been observed. Dynamical parallaxes of 556 double stars have been published by J. Jackson and H. H. Furner (12); from these the absolute magnitudes and linear velocities (transverse to the line of sight) were calculated. The magnitudes showed clearly the bifurcation into giants and dwarfs. The linear velocities were combined to give a determination of the sun's motion through the stellar system, the result being a velocity of 19·1 km. per sec. towards the Apex R.A.273°, Dec.+34°. This agrees remarkably well with the values generally accepted; and in particular the accordance of the speed with the value 19·5 km. per sec., obtained from the discussion of spectroscopic radial velocities, shows that the assumed mass 2·0 × sun must be almost exactly the average mass of a double star system.

Fixed Calcium Lines.—In certain spectroscopic binaries, the curious phenomenon of "fixed calcium lines" is observed. Whereas the other lines of the spectrum shift to and fro as the star approaches and recedes in its orbit, the narrow K line of calcium remains stationary. It is clear that there must be, somewhere between us and the star's surface, an absorbing cloud of calcium vapour, which does not follow the star in its orbit. The phenomenon was first pointed out by Hartmann in 1904 for the star δ Orionis; more recently it has been observed in other cases, and more than 20 such stars are now known. All belong to the very hottest spectral class Oe-B2; but this is not so significant as is often supposed, because at lower temperatures the K line appears in the spectrum of the star itself and would confuse the observation of the fixed calcium cloud. There are two possibilities, (*a*) that the cloud surrounds the whole binary system, the components revolving within it without appreciably disturbing it, (*b*) that the cloud has no connexion with the star, but consists of calcium vapour perhaps distributed widely in interstellar space. The hypothesis (*a*) was apparently contradicted by the fact that measures of the velocity of the fixed cloud did not agree with that of the centre of mass of the binary system; but the differences are not large, and may perhaps be ascribed to errors of observation or other causes of spectral shift. Hypothesis (*b*) seems the simplest; it suggests that vapours in very minute quantities may be diffused through space or float in extended clouds; the rarity of detection is due to the fact that the corresponding "fixed" spectral lines would in most cases be blended with similar absorption lines occurring in the atmospheres of the stars. Miss Heger at the Lick Observatory has recently discovered that the sodium lines D_1 and D_2 in δ Orionis are also "fixed."

Cepheid Variables.—Many new facts have emerged with regard to the class of short-period variable stars typified by δ Cephei. The three leading classes of variable stars are (*a*) long-period variables, (*b*) eclipsing variables, (*c*) Cepheids. In the first-named, the variation is undoubtedly due to a physical process in the star itself, which alternately blazes up and subsides; in the second, we have to do with a double star and the change of brightness is due merely to eclipses of one component by the other; the conditions which cause the variation of the third class—the Cepheids—are much more puzzling. The first question is: Is the Cepheid a binary star? The spectroscope *apparently* answers in the affirmative, for it shows a radial velocity increasing and decreasing in the period of the light fluctuation; it has generally been taken for granted that this must represent orbital motion. But the change of light cannot be attributed to eclipses; not only is the light curve of a different character, but minimum brightness always occurs when the star is receding most rapidly—at a time when the other component could not be between it and us. There must be an actual variation in the rate of radiation by the star, and this has been confirmed by H. Shapley (13), who showed that the spectral type (and presumably the surface temperature) changes during the period. For example, δ Cephei changes from type F0 at maximum to G2 at minimum; this periodic heating and cooling is the main cause of the change of brightness. One suggested explanation is that the orbital motion occurs in a resisting medium, so that the front side of the star is brighter than the rear side on account of the impact of the medium; this would explain why minimum brightness always occurs when the star is retreating. But opinion is now tending towards a pulsatory theory proposed by H. Shapley (14) which rejects the binary hypothesis altogether. The fact is that there is literally no room for the supposed second component required by the binary hypothesis. The Cepheids are giant stars filling a large volume, and the "orbit" is always small compared with the dimensions of the star itself. When we calculate the size of the orbit of the supposed companion (which we can do, knowing the period and approximate mass of the system) we find that it would graze or even lie inside the principal star—a *reductio ad absurdum* of the binary hypothesis. Further, a relation has been found between period and density in these stars which points to the period being determined by intrinsic conditions; such a relation is quite unintelligible if the period is provoked by an external cause, viz. the revolution of a companion. Accordingly Shapley suggests that the variable is *a single star which dilates and contracts with a regular pulsation;* and the observed motion of approach and recession refers, not to the star as a whole, but to the upheaval and subsidence of the part of the surface presented towards us.

The radius of δ Cephei may be taken as about 15,000,000 km.; the semi-amplitude of the oscillation, according to the observed radial velocities, is 1,370,000 km., or about 9% of the radius. For 15 other fully observed Cepheids the semi-amplitude of the pulsation ranges from 4 to 14% of the radius; this seems an amount of compression and expansion suitable to produce the rather large changes of temperature required. Within narrow limits the period is inversely proportional to the square root of the star's mean density, a relation which seems significant in view of the fact that the pulsations of a gravitating sphere follow this law. Moreover the constant of proportionality is of the order of magnitude predicted by theory·

[1] That is, 17 times the sun's mass.

we can calculate that a globe of gas having the mass and density of δ Cephei will vibrate in a period between 4 and 10 days (varying between these limits according to the adiabatic constant of the material of which it is composed); the observed period is 5·37 days. The most serious objection urged against the pulsation theory of Cepheids is that it requires a broadening of the spectral lines at minimum and maximum, because all parts of the disc would not be moving with the same speed in the line of sight; this has not yet been observed. It is to be hoped that this crucial but rather difficult effect will be thoroughly sought for in the near future. It may be remarked that some variation of light will arise directly from the dilatation and contraction of the surface; but this is not the leading variation since the actual maxima and minima occur when the star is passing through its mean volume. The indirect effect of the compression, changing the rate of flow of radiation, is much more important; and although the detailed mathematical discussion of the problem has not proved tractable, there is a general accordance of theory and observation.

The name "Cepheid" was at first restricted to stars with periods usually between three and eight days; but longer and shorter periods have been found, and it is now recognized that the "cluster variables" with periods less than a day are of the same nature. These occur abundantly in several of the globular clusters. In examining a globular cluster we have the great advantage that all the stars under review are at practically the same distance from us, so that *apparent* differences of brightness are *real* differences of brightness, and are not confused by effects of distance. Now it is found that in a globular cluster Cepheids of the same period have all the same brightness; so that a Cepheid of definite period is a standard object, whose absolute brightness will presumably be the same under all circumstances. This remarkable uniformity was first noticed by Miss Leavitt for the variables in the Lesser Magellanic Cloud; the results have since been extended by Shapley who has calculated the curve connecting luminosity with period. It appears that the Cepheids are among the brightest and probably the most massive stars, ranging in absolute magnitude from $-1^{M}\cdot5$ for periods of three days to $-4^{M}\cdot0$ for 18 days, and so on. Most are of spectral type F–G, becoming redder as the period lengthens; those with periods under a day are of type A. The range of the variation in magnitude is generally between $0^{m}\cdot5$ and $0^{m}\cdot9$, but doubtless many with smaller variations escape notice. The Pole Star is a Cepheid with a light range of only $0^{m}\cdot1$ and a period of 3·97 days.

Novae.—Two "new stars" of unusual brilliance have appeared in recent years. Nova Aquilae III. was discovered independently by a great many observers on June 8 1918, when it was already a first-magnitude star. Its earlier history has been supplied from an examination of photographic records of the sky. From 1888 onwards it remained steady at $10^{m}\cdot5$ and a photograph taken by Max Wolf three days before discovery showed that it was still normal. Incidentally we may note that it cannot have been a red star (types K or M) or it would have appeared in visual catalogues. On June 7 it had reached 6^{m} according to a Harvard photograph. The next day (when it was discovered) it had brightened to $0^{m}\cdot8$; and on June 9 it was only slightly inferior to Sirius. Then followed the usual slow decline with occasional fluctuations; and it had faded to $5^{m}\cdot5$ by the end of October. W. F. Denning discovered a Nova in Cygnus on August 20 1920, which reached the second magnitude. Its earlier history is unknown, but it must have been fainter than 15^{m} in 1908.

Broadly speaking each Nova reproduces the same sequence of phenomena with remarkable faithfulness (15). At the brightest the spectrum is that of a star of type A5. A few days later broad emission lines appear by the side of corresponding absorption lines which are strongly displaced to the violet. The absorption lines become doubled and tripled, as though there were several layers of uprushing gas travelling at different speeds in the line of sight. About a fortnight after maximum bright nebula lines appear; the continuous spectrum weakens and the star's light now comes mainly from emission lines. After some months the spectrum approximates to that of a planetary nebula. The great speed of upward rush of the absorbing gases is very remarkable, velocities of the order 2,000 km. per sec. being observed; there is no reason to doubt that these velocities are genuine, for the star expands and in the later stages shows a visible disc in large telescopes. The observed rate of spreading seems to agree with the speeds indicated by the spectroscope. Many theories have been suggested to account for the outbreak. A collision of two stars seems unlikely on account of its statistical improbability; and, moreover, the regular sequence of changes could scarcely be started by a haphazard impact. An eruption from within, whether occurring spontaneously at a certain stage of evolution or precipitated by the entry of the star into a nebula, may be more likely; but this theory also presents difficulties. J. H. Moore has recently obtained evidence that the extended nebulous disc, which is ultimately formed, shows differential motions of rotation in different parts. In any case it seems likely from the very rapid sequence of changes that the main outbreak is only skin-deep. Novae always occur within the limits of the Milky Way (or in spiral nebulae); but this may perhaps be due to the greater depth of the stellar universe in this direction. So far as can be judged the Nova before the outbreak is a dwarf star; and at least in the case of Nova Aquilae it cannot have been a very red star. (The long-period variables, whose violent outbreaks are rather suggestive of the explosion of a Nova, are giant red stars.) We may meditate on the fact that the stars subject to these catastrophes are probably in about the same stage of evolution as that through which the sun is now passing.

Stellar Velocities.—In 1910 J. C. Kapteyn and W. W. Campbell announced independently that (after allowing for the solar motion) the average speeds of the stars increase continuously as we pass through the spectral series from type B to type M. Kapteyn deduced the result from the proper motions, and Campbell from the spectroscopic radial velocities. At that time the older view, that the progression from B to M was the order of evolution, held the field; and it seemed as though the motion of a star must increase as it grows older. But the giant and dwarf theory shows that it is not a question of stage of evolution.

Take for example Campbell's figures: the average radial speeds are—type B, 6·5; A, 10·9; F, 14·4; G, 15·0; K, 16·8; M, 17·1 km. per second. In this investigation the K and M stars were almost all giants, so that so far as this analysis goes the youngest stars have the highest speeds; but Eddington found that the dwarf K and M stars at the other extreme in the sequence of evolution have still higher speeds. Of the 19 nearest stars, the nine brightest have a mean transverse speed of 29 km. per sec. (corresponding to a mean radial speed of 18·5 km. per sec.) whereas the 10 faintest, with luminosities less than $\frac{1}{10}\times$ sun, have a mean transverse speed of 68 km. per sec. (=radial speed 43 km. per sec.). W. S. Adams confirmed this by determination of the radial velocities; of 16 stars whose luminosity is less than $\frac{1}{10}\times$ sun, the mean radial velocity is 36 km. per sec. or more than twice that of the giant stars of the same type. Similar results were found in a more extensive statistical investigation by Eddington and Hartley. Finally Kapteyn and Adams (16) announced a general progressive dependence of velocity on absolute brightness, the faintest stars having the greatest average speed.

We see then that there is a correlation of speed both with spectral type and with luminosity. It seems likely that the primary association is between speed and mass, the dependence on luminosity and spectral type being due to the correlation of these with mass; as already mentioned, only the most massive stars can reach the hottest spectral types. If this view is correct we must regard the quick-moving dwarf stars of types K and M as having particularly low masses—either because the smallest stars run their course of evolution more quickly, or because mass has been lost along with the energy radiated during their past history. The last suggestion may seem extravagant, but it must be pointed out that all energy has mass; so that a radiating star is continually losing mass; the only question is whether the life of the star is long enough for this loss of mass to amount to anything appreciable; and as to the length of life the most widely divergent views are current. With regard to the explanation of this association of speed and mass, J. Halm (17) has advocated the tempting hypothesis that it is an example of the equipartition of energy—brought about by the laws of statistical dynamics exactly as in a gas where molecules of different masses are mixed. But starting with an arbitrary mixture of stellar velocities, it would take about 10^{14} years to approach this equipartition by mutual perturbations of the stars; and most astronomers shrink from attributing such an age to the stellar universe. A simpler suggestion is that the small stars were formed in the outer parts of the stellar system, where star-forming material was more rarefied; and they have acquired greater velocities by the longer fall towards the central region where we now observe them.

The Star Streams.—Many researches have confirmed Kapteyn's discovery that the stars (or at least those near enough for investigation) move preferentially in two favoured directions. Since the article STAR (*see* 25.784) was written, the spectroscopic radial velocities have become available for testing the theory and they confirm it decisively. Relatively to the sun the favoured directions are inclined at about 120° (the apices being at R.A.96° Dec.+8°, and R.A.290°, Dec.−54°); but referred to the mean of the stars they are necessarily two opposite directions along a straight line. The extremities of this axis of preferential motion are called the *vertices*. The following appear to be the most accurate determinations of the vertex by the two independent methods (18):—

From proper motions (Boss's catalogue) R.A.94°·2, Dec.+11°·9.
From radial velocities (Lick catalogues) R.A.94°·6, Dec.+12°·5.

It is significant that the line of preferential motion lies exactly in the galactic plane. The phenomenon may be due to two great systems of stars passing through one another; or it may represent some dynamical condition of a single system. The latter view has often been favoured, mainly owing to the very elegant mathematical specification of the corresponding velocity distribution given by K. Schwarzschild's ellipsoidal theory (19).

H. H. Turner (20) suggests that if the stars were originally formed as an extended system with little or no initial motion, the system would settle down to a steady state in which the motions were preponderatingly radial; so that, assuming that the sun is placed excentrically, the stars in its neighbourhood would be moving preferentially in the line towards and away from the centre. An analogy is afforded by the comets in the solar system, which, observed from an outer planet, would appear to move preferentially towards and away from the sun. This explanation seems satisfactory on the whole. It may be objected that, according to statistics of distribution of the stars, the dynamical centre of the stellar system appears to be, not in the direction of the vertex, but 90° away; and the view favoured by Strömberg and by Jeans is that the star-streaming is due to predominant transverse (circular) motion rather than radial motion. It is difficult to see how such a state of motion could originate. H. Shapley has, however, shown that the "local system" (considered in studies of stellar distribution) is but a small part of a greater galactic system; we are on the outskirts of the latter, and its centre is in the direction R.A.262°, Dec. −30°, agreeing reasonably well with the line of preferential motion.

The more detailed study of the systematic motions of the stars leads to great complexity. After the first approximation outlined above, we have to recognize a third drift, pointed out by J. Halm, which seems to be nearly at rest relative to the mean of the other two. The striking feature is that the type B stars appear to belong to this third drift, and a statistical discussion of their motions shows no indication of the preferential motion, which is always conspicuously manifested (though in somewhat different degrees) by the stars of other types. All this complexity is probably a sign that the stellar system is not in any approximate equilibrium, but is progressing towards a steadier configuration.

Moving Clusters.—Many years ago R. A. Proctor pointed out a group of stars in the neighbourhood of the Hyades with practically equal proper motions; the researches of L. Boss (21) have thrown new light on the nature of this association. He recognized as belonging to the group 39 stars spread over an area 15° square; the motions appear to converge towards a certain point in the sky—a perspective effect which would naturally occur if the actual motions in three dimensions are parallel; the direction of the convergent point gives the direction of the common motion of the group relative to the sun.

Knowing the spectroscopic radial velocity of one or more members, we can by an easy geometrical construction find the whole linear velocity and also locate each star separately in space. We thus obtain exceptionally full and exact information as to the distances and luminosities of this group of stars. The cluster is roughly spherical with a diameter of 10 parsecs; there must be many non-associated stars—accidental interlopers in so large a region—and perhaps the most significant conclusion is that the casual attractions of these stars have not been able during the lifetime of the cluster to disturb appreciably the parallelism of the motions and so scatter the cluster. Another remarkable "moving cluster" is formed of five stars of the Plough together with stars widely separated in the sky, including Sirius, α Coronae and β Eridani. Similar associations are specially frequent among stars of the B type of spectrum, one of the most distinct being a chain of stars crossing the constellation Perseus.

Number and Distribution of Stars.—Important statistics of the number of stars down to various limits of magnitude have been obtained by Chapman and Melotte and by P. J. van Rhijn. We give some results of the latter investigation which is the more recent (22).

The total number of stars down to photographic magnitude $16^m{\cdot}0$ is 33,000,000; by a somewhat risky extrapolation it is estimated that the total number of stars in the system is between three and four thousand millions, and to reach half this number it would be necessary to go as far as magnitude $25^m{\cdot}5$. (Exactly what is meant by the "system" in the foregoing sentence is somewhat difficult to define; there may, of course, be exterior galaxies or extensions which are not reckoned in these counts.) An important point is the well-known flattened distribution of the stars; up to magnitude 16^m, the stars are distributed in the galactic plane 5½ times as thickly as at the galactic poles. This is an increase compared with the concentration of the brighter stars; up to magnitude 5^m, the corresponding ratio is 2½. We can easily understand this greater concentration of the faint stars, since on the average they carry us to greater distances, at which the oblate shape of the stellar system has more pronounced effect.

Taking a lower limit of luminosity 1/200 × sun, it is estimated that there are 30 stars within a sphere of five parsecs radius round the sun; about 20 of these have actually been identified. If this star density persisted, a sphere of 1,500 parsecs radius would contain 800 million stars, besides an unknown but probably rather large number of extinct stars and of stars giving less than 1/200th of the sun's light. This gives some idea of the possible extent of the star cloud to which we belong; there can be little doubt that the density must fall off very considerably at distances not greater than 1,500 parsecs, more especially in the directions of the galactic poles.

The following table based on an investigation by Kapteyn, van Rhijn and Weersma (23) shows the average parallax of stars of different magnitudes:—

Mag.	Mean Parallax.	Mag.	Mean Parallax.
$1^m{\cdot}0$	·060″	$7^m{\cdot}0$	·0090″
$2^m{\cdot}0$	·044″	$8^m{\cdot}0$	·0065″
$3^m{\cdot}0$	·032″	$9^m{\cdot}0$	·0047″
$4^m{\cdot}0$	·023″	$10^m{\cdot}0$	·0034″
$5^m{\cdot}0$	·017″	$11^m{\cdot}0$	·0025″
$6^m{\cdot}0$	·012″	$12^m{\cdot}0$	·0018″

It is an even chance that a particular star has a parallax between 0·23 and 1·13 times the average parallax for its magnitude.

Globular Clusters.—About 70 globular clusters are known, distinguishable from the loose irregular star clusters by their symmetrical and condensed appearance. These have been the subject of a remarkable series of researches by H. Shapley (24).

It has already been mentioned that some of them contain many Cepheid variables, whose absolute luminosities are known from their periods. Thus in Messier 3 (Canes Venatici) the mean magnitude of 110 Cepheid variables is $15^m{\cdot}50$, the individual stars deviating as a rule no more than $0^m{\cdot}1$ from this mean. In the cluster ω Centauri 76 variables concentrate with similar closeness about a mean magnitude $13^m{\cdot}57$. It is clear that the difference $1^m{\cdot}93$ must correspond to the greater distance of Messier 3; and we easily deduce that the ratio of the distances is 2·43, this ratio being very accurately determined. We are not quite so certain of the absolute distances of the two clusters; but the evidence seems to indicate that the absolute magnitude of these variables (with periods less than a day) is $-0^M{\cdot}2$, which gives the following distances—ω Centauri, 5,800 parsecs; Messier 3, 14,000 parsecs. When it is recalled that the usual trigonometrical method can scarcely be applied to determining distances greater than 20 parsecs, the extraordinary power of this method of plumbing space will be realized. The method was first used by E. Hertzsprung to determine the distance of the Lesser Magellanic Cloud.

By this method, and by supplementary devices, Shapley has been able to plot the distribution of the globular clusters in space and to form an idea of the extent of the system which they outline. Even in this vaster system the galactic plane is still a plane of symmetry and of flattening though the clusters extend to great distances above and below, the average distance from the plane being eight kiloparsecs. In plan the system is elongated with its axis in galactic longitude 325°—nearly the direction of star streaming; the greatest diameter is at least 60 kiloparsecs, and the sun is near one end of it so that practically all the globular clusters are found in one hemisphere of the sky. The most remote cluster known is distant 67 kiloparsecs or 200,000 light years. We have to recognize that the "stellar system," dealt with in the researches described previously, is but a small star cloud in this greater galactic system. Roughly speaking those researches may be considered to relate to a domain of about 800 parsecs radius; the sun seems to be fairly centrally placed in the local star cloud (about 90 parsecs from the centre, according to Charlier), but this is on the outskirts of a greater system whose centre is 20,000 parsecs away.

In the foregoing deductions Shapley neglects any possible loss of apparent brightness owing to absorption of light in space. Anything of the nature of a fog or scattering medium would cause greater loss of light in the blue than in the red, and would consequently betray itself by a general reddening of the light of the more distant stars. Such a reddening has been sought for by King, Kapteyn, H. S. Jones, and others, and provisional estimates of the extinction have been made. Shapley considers that the extinction must be altogether negligible, resting his case on the observation that the colour-indices of stars in clusters range from $-0^m{\cdot}5$ to $+1^m{\cdot}9$ just as those of the nearer stars do. It seems therefore impossible that their light can have been reddened by a scattering medium. The general absorption in space must be so low that a ray of light proceeding through interstellar space can travel for 3,000 years without meeting obstacles sufficient to deflect 1 % of its intensity. Nevertheless there are large tracts of obscuring material in particular regions, which hide more or less completely the stars behind. These are found especially in the Milky Way, and consist of dark or faintly-luminous nebulae often of great extent; perhaps there is no hard and fast division between them and the

irregular gaseous nebulae like the Orion nebula. A large obscuring tract in Taurus is estimated by A. Pannekoek to be at 140 parsecs distance; this may be compared with Kapteyn's value 190 parsecs for the Orion nebula. A catalogue of 182 dark markings in the sky has been given by E. E. Barnard (25).

Nebulae.—Whereas the irregular gaseous nebulae are comparatively near, and within the local star cloud, the spiral nebulae are now considered to be exceedingly remote—perhaps more remote than the globular clusters. According to one view, they are "island universes" coequal with the great galactic system. Others would consider them rather as outlying dependencies. Unfortunately we have no trustworthy knowledge of their distances; estimates have been made from the apparent magnitudes of the novae which have appeared in them, but these seem to be very speculative. The spirals have been found to possess extraordinarily great velocities in the line of sight and in general the motion is directed away from the sun. This seems to argue a lack of dynamical association with the galactic system. The mean speed of 15 spirals measured by Slipher, is about 400 km. per sec. Independent determinations by Slipher, Wright, and Pease agree well on a velocity of 300 km. per sec. for the Andromeda nebula; for some nebulae speeds exceeding 1,000 km. per sec. have been found. The Theory of Relativity suggests an interesting explanation of these high speeds, and more particularly the preponderance of receding velocities. De Sitter's form of the theory of curved space-time actually predicts an effect of this kind for very remote objects (26).

The planetary nebulae are presumably much less distant. They have a well-marked galactic concentration; but the solar motion referred to them is apparently not the same as that referred to the stars. They do not show preferential motion along any axis. The average radial velocity is 30 km. per sec.—about the same as that of the fastest class of stars (the red dwarfs). When the planetary nebulae are photographed with an objective prism of large dispersion, it is found that the various monochromatic images are of different forms and sizes; so that important information is obtained as to the distribution of the emitting gases through the nebula. Perhaps the most fundamental problem presented by these objects is whether all parts of the disc are independently self-luminous, or whether the light-emission is stimulated by radiation coming from a central star or nucleus.

II. Theoretical Astronomy

Gravitation.—The epoch-making theory of gravitation, put forward by Einstein in 1915, is described in the article Relativity. We refer to it here because the new law of gravitation, required by his theory, removes the most outstanding divergence between theory and observation in the solar system—viz. the progression of the perihelion of Mercury. There is still some discrepancy between theory and observation for the motion of the node of Venus; but this is a much smaller residual, and may perhaps even be attributable to accidental errors. Einstein's predicted deflection of light by the sun's gravitational field was verified by the British eclipse expeditions in 1919. His third crucial test—a general displacement of spectral lines to the red in the sun as compared with terrestrial sources—was still in 1921 a subject of controversy.

E. W. Brown's lunar theory, developed according to the methods of G. W. Hill, was completed by the publication in 1920 of full *Tables of the Moon's Motion.* It seems safe to say that no term of appreciable significance has been omitted; nevertheless the moon deviates unmistakably from its theoretical place in an irregular manner. An investigation by H. Glauert (27) seems to show that the irregularities are at least partly due to variations in the rate of our standard timekeeper, viz. the earth's rotation; for the longitudes of the sun, Mercury and Venus exhibit similar irregularities, and the curves closely resemble one another. Besides these irregular changes, there is a general secular acceleration of the moon, which, being cumulative, leads to large changes in the circumstances of ancient eclipses. The historical evidence of all kinds has been rediscussed by J. K. Fotheringham (28) who arrives finally at the values 10″·5 for the moon's secular acceleration[1] and 1″·0 for the sun's secular acceleration. These quantities are presumably attributable to tidal friction which causes a direct acceleration of the moon's orbital motion, as well as a spurious acceleration through the increase in the length of the standard of time.

It is now believed that the bodily tides in the earth have little effect and that the most effective retardation is due to tides in land-locked and shallow seas. According to G. I. Taylor the Irish Sea alone contributes $\frac{1}{50}$ of the total dissipation of energy.

Evolution of Rotating Masses.—The figures of equilibrium and the final disruption of rotating fluid masses have been studied in great detail by J. H. Jeans. In agreement with Liapounoff he has found that the so-called "pear-shaped" figure of equilibrium, which succeeds the Jacobi ellipsoidal form, is unstable. For a full account of his conclusions as to the evolution of double stars, spiral nebulae and clusters reference must be made to his book *Problems of Cosmogony and Stellar Dynamics.* With regard to the solar system, he finds himself unable to account for the formation of the planets by rotation alone; and he attributes them to a tidal disruption of the sun having occurred at some distant epoch in the past. If this view is correct the system of the planets is a "freak of nature," owing its existence to a chance encounter of some larger star (which approached within less than the sun's diameter from its surface). Few, if any, other systems of this kind can have been formed; and the common view that the stars in general are attended each by a system of planets may be entirely mistaken.

Mathematical investigations of the possible steady states of a system of stars moving under gravitational forces have been made by Charlier, Jeans and Eddington (29). It appears that the actual conditions are such that each star describes an orbit under the averaged attraction of the whole mass, the casual perturbations of a star by its immediate neighbours being negligible. For a spherical distribution, a steady system can be found in which there is preferential motion in a radial direction, illustrating H. H. Turner's explanation of star-streaming. An oblate system can also be in a steady state with radial star-streaming, provided that it is not alone but forms part of a larger system in which the mass as a whole is distributed spherically. It appears fairly certain, however, that an isolated oblate system moving under its own attraction cannot be in a steady state. For this and other reasons we believe that our own oblate stellar system is by no means in dynamical equilibrium, but is collapsing towards some more permanent form.

H. von Zeipel and H. C. Plummer (30) have found that the distribution of stars in globular clusters conforms to a definite law, which is in fact the adiabatic law of density of a gravitating sphere of gas for which γ has the critical value 1·2. Although this appears to have important dynamical significance, no very satisfactory explanation can be given.

Radiative Equilibrium of the Stars.—The discovery that many of the stars—the giant stars—are diffuse globes of very low density, gives a stimulus to investigations of their internal conditions of equilibrium; for the material, being practically a perfect gas, will obey comparatively simple laws. In the earlier researches of Lane and Ritter it was supposed that the equilibrium was adiabatic—that is to say, the material was continually stirred by convection currents, hot gases ascending to replace the continually cooling material at the surface. But it is now clear that the heat passes to the surface not by material transfer but by radiation; and the condition of equilibrium is that each element will settle down to the temperature at which it radiates an amount of heat equal to that which it absorbs from the radiant heat flowing through it. This was first pointed out as probable by R. A. Sampson, and the theory of radiative equilibrium was developed by K. Schwarzschild for the external layers of the sun. Eddington (31) has based on this principle a theory of the equilibrium throughout the interior of a star.

At first the principal unknown constant was the molecular weight of the material of the star. It was, however, pointed out by Newall and Jeans that the atoms were probably strongly ionized at the high temperatures prevailing; and this led to a simple solution of the difficulty. The number of electrons surrounding the nucleus of any atom is approximately half the atomic weight; hence if all the electrons break loose, the average molecular weight will in all cases be approximately 2, since each unattached electron counts as a separate molecule. Ionization is probably not complete and both theory and observation seem to be best satisfied by a value between 3 and 4; but any large uncertainty as to the molecular weight is thus removed. The calculation shows that the rate of radiation of energy of a gaseous (giant) star is given by:—

$$L = \frac{4\pi c G}{k} M \ (1-\beta)$$

where M is the mass, G the constant of gravitation, *c* the velocity of light, *k* the mass-coefficient of absorption of radiation by the material, and β a constant depending on the mass and obtained by solving the quartic equation

$$1-\beta = 0{\cdot}0026 \ M^2 m^4 \beta^4$$

where M is the mass in terms of the sun, and *m* the molecular weight in terms of the hydrogen atom. The density does not enter into

[1] The moon goes ahead by the amount 10″·5T², where T is the time in centuries. This is the conventional definition of "secular acceleration" in this connexion.

the formula for the rate of radiation; and hence (provided k remains constant) a star will radiate the same amount of energy as it passes through all stages of evolution until it becomes too dense to behave as a perfect gas. This agrees with the observed fact that the average magnitudes of the giant stars are approximately the same for all spectral types. The formula shows also that the total radiation (and, subject to calculable corrections, the absolute luminosity) is a function of the mass, and it becomes possible to calculate the mass from the luminosity—and *vice versa*. Thus the great majority of the giant stars of types F and G are comprised within absolute magnitudes $2^M{\cdot}0$ to $-0^M{\cdot}5$; these correspond to masses 0·07 to 1·6 times that of the sun—an illustration of the great uniformity of stellar masses. The constant k must be obtained from our general knowledge of the radiation of giant stars of known mass; it is approximately 20 C.G.S. units, that is to say, radiation after passing a column of stellar material of 1/20 gram per sq. cm. would be reduced to one-third (strictly $1/e$) of its original intensity. This is a very high opacity, but it is of the same order as that found in laboratory experiments on X rays, to which the high temperature radiation within the stars is closely akin. It is remarkable that k appears to vary very little from one star to another in spite of their considerable differences of temperature.

Taking account of the deviations from the laws of a perfect gas, the theory can be extended (though with less certainty) to dwarf stars. The most interesting point is to determine the maximum temperature attained by stars of different mass. Measuring the mass in terms of the sun, a mass ¼ should just attain effective temperature 3,000° (type M), below which it would scarcely appear luminous; a mass ½ attains 6,000° (type G); mass 1 attains 9,000° (type A5—F); and mass 2·5 attains 14,000° (type B5). These results will no doubt be revised when better information is available for checking the constants of the theory; but they appear to be reasonably probable.

Radiation Pressure.—It is found that the pressure of radiation plays a very important part in the dynamical equilibrium of the giant stars. As already mentioned the stellar material is highly opaque to the radiation; thus the outflowing radiation exerts a large pressure on the absorbing material, tending to support part of its weight. The fraction of the weight carried by the radiation pressure is the quantity $(1-\beta)$ in the formula already given. For example (taking molecular weight 3·0) we find:—

For star of mass ½ × sun radiation pressure supports 0·044 of weight
" " " " 5 × " " " " 0·457 " "

This gives a clue to the remarkable phenomenon that the masses of the stars are so nearly uniform. Why should the matter of the universe have aggregated into lumps, whose size is almost always between ½ and 5 × sun? We see that this is just the range for which radiation pressure rises from insignificance to importance, and presumably that fact has determined the size of stellar masses. On general grounds it is likely that when radiation pressure counterbalances a considerable part of gravitation, the body would be very liable to disruption; accordingly the chances of survival of stars more than five times as massive as the sun, would be small. The material has thus tended to divide and subdivide until the separate masses fell just below the danger limit, fixed by this criterion of radiation pressure; and afterwards there was no cause for further division.

Age of the Stars.—In discussions of the evolution and dynamics of the stars or of systems of stars, the problem arises: What is the time-scale of the process? If astronomers were asked to estimate the length of life of a star from its first luminescence to its final extinction, the answers would probably fall into three groups: (*a*) The short time-scale, urged by Kelvin, giving a life of about 20 million years; (*b*) a long time-scale, say 10^{10} years; (*c*) an *ultra*-long time-scale of 10^{16} years and upwards urged by those who believe the stellar universe to have approximately reached statistical equilibrium. Belief in the short time-scale rests on Helmholtz's theory that the star's heat comes from the gravitational energy converted as it contracts; in recent years, the cumulative evidence against this "contraction theory" of a star's energy has become very considerable, and it now seems clear that the star must have some much larger store to draw on.

The Cepheid variables may perhaps afford us a measure of the rate at which the evolution proceeds. Like other giant stars, δ Cephei would need to condense very rapidly if the energy which it radiates came solely from contraction: the increase of density must in fact amount to 1% in 40 years. As already explained the period of the light variation is intrinsic, and should therefore change as the density changes. Calculation shows that the period ought to decrease 40 seconds annually. Now δ Cephei has been under careful observation since 1785 and the decrease of period is only just detectable. The value given by E. Hertzsprung is a decrease of 0·08 second per annum. Thus at the present stage evolution is proceeding at a rate no more than $\frac{1}{500}$ of that required by the contraction hypothesis: and some source of energy is being drawn on to prolong the star's life 500-fold. Assuming that this store of energy is contained in the star (and not picked up continually from space), it seems clear that it must consist of the sub-atomic energy, releasable when the elements are transmuted or possibly when positive and negative electrons annihilate one another. Since all kinds of energy possess mass, an upper limit to the store can be given; the sun's output of heat could be maintained for $15{\cdot}10^{12}$ years if all the energy contained in it were liberated.

III. Instruments

The Hooker telescope, a reflector of 100 in. aperture, installed at Mount Wilson Observatory, is now (1921) the most powerful telescope in the world. It was brought into regular use in 1919. The mirror is a glass disc of thickness 12·8 in. at the edge and 11·6 in. at the centre, weighing over four tons. It is ground to a focal length of 12·88 metres, but can be used with convex mirrors as a Cassegrain with equivalent focal lengths of 48 and 76 metres. The weight on the polar axis is mainly buoyed by cylinders floating in mercury. A 72-in. reflector has been erected at Victoria, B.C. Both these large telescopes are giving excellent performance.

A comparatively small telescope of interesting design was constructed by the late B. Cookson at Cambridge; it is a photographic zenith telescope carried on an annulus which floats in mercury. Rotation about the true vertical is thus secured by flotation instead of by reading spirit levels. After Cookson's death the instrument was removed to Greenwich, where it has been used with great success for determining latitude variation and the constant of aberration. From seven years' observations the value 20″·44 I ″·013 was obtained for the constant of aberration; this is probably the best direct determination of the constant, though scarcely so accurate as the value 20″·47 obtained indirectly from the solar parallax. A somewhat similar instrument in which rotation about the vertical is obtained by suspension instead of by flotation has been recently installed at Durham Observatory.

An appliance very much used in recent years is a coarse grating consisting of parallel and equidistant metal strips placed in front of the object glass. This grating, with say five "lines" to the inch, seems like a travesty of the diffraction gratings used by physicists; but the action is essentially the same. On either side of the undiffracted image of the star subsidiary images appear, which are in reality spectra of the first, second and higher orders. The distance between the two first order images is proportional to the average wave-length of the light; and hence the grating can be used for determining star colour on a quantitative scale. It also provides a convenient means of obtaining images whose intensities are in a definitely known ratio (calculated from the widths of the strips and spaces), which is of great value in determining an absolute scale of photographic magnitudes. These objective gratings appear to have been first used by K. Schwarzschild acting on a suggestion from A. A. Michelson. Another optical device, suggested by A. A. Michelson so long ago as 1890, has recently been used with great success at Mount Wilson. An interferometer consists essentially of two light-collectors of moderate aperture separated by a base-line of considerable length (as in a range-finder). The beams of light are then brought together, so that for a point source they produce the usual interference fringes. As the base-line extends or contracts the fringes narrow or widen in proportion. For a double star a length and orientation of the base-line can be found in which the bright fringes of one component fall on the dark intervals of the other component, so that the visibility of the fringes is a minimum. In this way the position angle and separation of the components can be measured with great accuracy, and the method is applicable to double stars too close to be resolved in a telescope; in fact the resolving power of the interferometer is greater than that of a telescope of aperture equal to the base-line. At Mount

Wilson excellent observations were obtained by this means of Capella (hitherto known only as a spectroscopic binary), the separation of the components being 0″·04. A still more interesting application was the measurement for the first time of the angular diameter of a star; this has been accomplished for Betelgeuse (which probably has the greatest angular diameter of any star); a base-line of 10 ft. was required for the disappearance of the fringes. The diameter of Arcturus has also been measured, the fringes disappearing when the base-line was 19 feet.

The photo-electric cell has been the means of great advance in stellar photometry. Films of the alkali metals emit electrons in numbers proportional to the intensity of the light falling on them. The light of a star is allowed to enter a cell coated with such a film and the rate of discharge of electrons is measured with an electrometer. In all other methods of photometry the effect observed is nearly proportional to the magnitude, and the photo-electric method is the only one which shows the luminosity directly and not distorted on a logarithmic scale.

A "Stereocomparator" is often used for detecting large proper motions between two plates taken at different epochs. The plates are arranged so as to be viewed one with each eye and combined stereoscopically; stars which have moved appreciably between the two epochs will betray themselves by appearing to stand out in front of or behind the general plane. In the modification called the "Blink-Microscope" the two plates are viewed in rapid alternation; and a motion or change of brightness of a star is detected by a tell-tale flicker.

ATHLETICS: *see* SPORTS AND GAMES.

ATHOS, MOUNT (*see* 2.851*).—In the summer of 1913 the monastic communities of Mount Athos were convulsed by the controversy arising out of the heresy of the Name of God. A Russian monk named Ilarion, in the western Caucasus, had published a book, under the title of *In the Mountains of the Caucasus*, in which he argued that the name of God, being part of God, is divine, and therefore to be worshipped. The book was printed at the Pecherski monastery at Kiev, esteemed the special press of the Holy Synod, and its popularity is shown by the fact that it passed into three editions. Its teaching as to the name of God, which claimed to be based on the authority of such eminent saints as St. Gregory Palemon and St. Dmitri of Rostov, was welcomed with enthusiasm by the monks of the monasteries of St. Andrew and St. Pentelemon, its chief exponent being Antony Bulatovich, an ex-officer of the Hussars of the Guard, who had become a monk at St. Andrew's.

The crisis began when Archbishop Antony of Volinsk denounced the doctrine as heretical in *The Russian Monk*. The monks appealed against this to the Holy Synod; but the synod declared against them and ordered the abbots to repress the heresy. The monks thereupon expelled the abbots by force, and their action was approved by the monastery of Vatopedi, the Greek parent house of St. Andrew's. On the appeal of the abbots the dispute was now referred by the Holy Synod to the court of the Patriarch of Constantinople, and the intervention of the Russian Government was invited. The condemnation of the "heretics" by the Patriarch led to their repudiation by the community of Vatopedi, and at the instance of the Russian ambassador at Constantinople the refractory monasteries were subjected to a rigorous blockade.

This failed to subdue the monks, whom the Archbishop of Volinsk described as "a hand of soft-brained idiots led by a vainglorious hussar." It was feared that the heresy, if suffered to make headway, would spread like wildfire among the ignorant Russian peasantry, and Archbishop Nikon was sent to Athos to threaten the recalcitrant brethren with severe temporal and eternal penalties should they remain obstinate. But his reception was worse than cold, and the Russian Government determined to take strong measures. On June 24, 200 Russian soldiers landed on Mount Athos, and a month later 600 of the monks were deported to Russia, where they were distributed as prisoners in various monasteries. The Holy Synod decided that the peculiar tenets of Bulatovich and his followers were to be known and condemned as "the heresy of the Name of God."

AUCTION BRIDGE: *see* BRIDGE, AUCTION.

AUFFENBERG-KOMAROW, MORITZ, FREIHERR VON (1852–), Austrian general of infantry, was born in Troppau. As a young staff officer he served in the army which occupied Bosnia in 1878. He later commanded the XV. Army Corps at Serajevo, and in the autumn of 1911 became Minister of War. The ambitious general had many enemies. His active spirit led him to take a vigorous part in the internal politics of the monarchy, his knowledge of the Hungarian and more especially of the Southern Slav question being intimate. He had attracted the attention of the heir to the throne, the Archduke Francis Ferdinand, who had, in spite of much opposition, secured his appointment as Minister of War; but powerful influences forced him to retire after only a year and a quarter's tenure of the office. He won his title in the World War, as the commander of the IV. Army against the Russians, by the brilliant victory of Komarow at the end of Aug. 1914. After the victory Auffenberg succeeded in the difficult operation of completely changing the front of his entire army, with which he moved southwards in time to take part in the second battle of Lemberg; but the superior strength of the enemy made it impossible for him to avert defeat. The general was then called on to resign his command. In April 1915 he was arrested on an accusation of having as War Minister delivered to an unauthorized person a copy of military instructions with a view to speculation on the Exchange, but the court acquitted him.

Auffenberg wrote two books: *Aus Oesterreich-Ungarns Teilnahme am Weltkrieg* and *Aus Oesterreichs Höhe und Niedergang.*

AUSTIN, ALFRED (1835–1913), English poet (*see* 2.938), died June 2 1913 at Swinford Old Manor, near Ashford, Kent. His autobiography appeared in 1911. He was succeeded in the laureateship by Robert Bridges.

AUSTRALIA (*see* 2.941).—Including as it does the adjacent island of Tasmania, but exclusive of its Papuan Territory (about 91,000 sq.m.), the area of the Australian Commonwealth was in 1921 computed at 2,974,581 sq.m., 1,149,320 of which, about five-thirteenths of the total, are within the tropical zone. Between 1901, when the Commonwealth was proclaimed, and 1921, there had been three changes affecting the political boundaries of Australia. In 1906 Papua (the British portion of the island of New Guinea) was taken over from the British Government and constituted a Territory of the Commonwealth. In 1909 the Commonwealth took over an area in the S. of New South Wales which was constituted a Federal Territory and on which was to be built the Federal capital. In 1910 the Northern Territory was taken over from S. Australia and constituted a Federal Territory. The effect of the World War in giving to the Australian Commonwealth, as mandatory under the League of Nations, control of what was German New Guinea and of other ex-German posses-

These figures indicate the volume and page number of the previous article.

sions in the Pacific area (roughly about 90,000 sq.m.) does not, strictly speaking, make any change in the area of the Australian Commonwealth since these "mandated" territories are not annexed.

Papua.—The suitableness of Papua for various forms of tropical agriculture is undoubted, but there is a "labour difficulty" in the way of progress. The Papuan, like most South Sea Islanders, has an aversion to steady work. In Fiji, a British colony in the S. Pacific, a position similar to that existing in Papua has been met by the importing of industrious coolies from India to develop the sugar plantations. The Australian Government, however, is determined to keep Papua for the Papuans. It was proposed in 1908 that the Papuan should be forced to do a certain amount of work, either for himself, for private planters, or for the Government, the argument being advanced that since nature was so bountiful as to keep him in reasonable comfort without work, he would never be driven to labour by necessity, and must, therefore, be brought under some other form of compulsion. The Australian Government vetoed the proposal. In 1918, however, a Native Taxes Ordinance was passed authorizing a tax not exceeding £1 per head on all natives except those in Government employ, or unfit for work, or having four or more living children. The proceeds of the tax will be applied to the benefit of the natives; its effect is designed to stimulate industry on their part. In 1919 about 13,000 natives were engaged in some form of contract labour. The Native Labour Ordinances safeguard strictly the interests of the native workers.

There are about 58,513 ac. under cultivation, mostly planted with coco-nut trees. Rubber, cotton, sisal, and coffee are also grown and mining and pearl-shelling are considerable industries. The system of land tenure is by leasehold; freeholds are not granted; the conditions of leasing are not onerous (*see* NEW GUINEA).

The Federal Territory and Federal Capital Site.—The constitution having provided that the capital of the Commonwealth should be within the state of New South Wales, at least 100 m. from Sydney, the New South Wales Government in 1909 surrendered to the Commonwealth Government some 900 sq.m. of territory around Yass-Canberra, and also an area of 2 sq.m. on the shores of Jervis Bay for the construction of a Federal port; and with these areas went the right to construct a railway from this port to the Federal Territory.

In 1910 the Federal Government took possession of the Territory. It established there in 1911 a military college and later a naval college at Jervis Bay. In 1913 the work of constructing the Federal city was formally begun. A railway connecting the site with the main line was opened in 1914. The World War seriously interfered with further progress and work on the Federal city was still in abeyance in 1921. About £1,000,000 had been spent.

The Northern Territory.—With an area of 523,620 sq.m. (more than one-sixth of the continent), having some very fertile land, and with a better river system than most other parts of Australia, the Northern Territory is almost empty and undeveloped. The total pop. (other than aborigines) was 4,706 in 1919. The backwardness of the Territory as compared with the rest of Australia is due chiefly to political causes. When the Australian colonies first set up separate households it was convenient to none of them to include the Territory, and it was left in the hands of the Imperial Government. In 1863 South Australia took over the responsibility for the Territory, intending to connect it with Adelaide by a north-to-south transcontinental railway. With such a railway it would have been brought within the ambit of South Australian development. Without that railway it was actually more remote from communication with South Australia than with any other of the states. The railway was begun. It reached Pine Creek from Port Darwin at the N. end, and Oodnadatta from Adelaide at the S. end; then hope of its completion was abandoned. When the Commonwealth came into existence it sought a transfer of the Northern Territory from South Australia. But it was not until Jan. 1 1911 that the final stage of the negotiations was reached and the Territory assumed by the Commonwealth. The terms of transfer were that all the past deficits incurred by South Australia in the administration of the Territory should be taken over by the Commonwealth, and that the trans-continental railway should be completed from Port Darwin in the N. to Port Augusta (near Adelaide) in the S. The Commonwealth purchased the existing state railway from Port Augusta to Oodnadatta. It has not yet been found possible to go on with this railway project, but, the east-to-west trans-continental railway being completed, the north-to-south in 1921 was being seriously discussed.

In 1912 the Commonwealth Government appointed an administrator for the Northern Territory and took preliminary steps for its development and colonization. As to the possibilities of a white population flourishing in this tropical part of the continent the evidence is reassuring. There is very little malaria, and other specific tropical diseases are absent. The land is generally considered to be suitable for cattle-grazing (there are great herds of wild buffalo) and tropical farming on the coast; for sheep-farming and dairy-farming on the tablelands. There is said to be mineral wealth, but mining results in the past have usually been disappointing. In its policy of development the Australian Government does not propose to allow any further complete alienation of Crown lands. All titles will be leasehold, but the leases will be in perpetuity, with reappraisement of rent every 14 years in the case of town lands, every 21 years in the case of agricultural and pastoral lands. Up to the present the Northern Territory has not proved a profitable acquisition for the Commonwealth. The year's accounts 1918-9 showed a deficit of £357,760 on an expenditure of £497,301. The administration has been disturbed by troubles similar in character to those which the Mother Country had with the Australian colonists in the early days of Australian settlement.

THE COMMONWEALTH

The Federal Act of July 1900 (*see* 2.966) united in an indissoluble Australian Commonwealth six self-governing colonies, organized as British settlements between 1770 and 1859, which retain their individuality and, for certain purposes, their independence. The federating states, New South Wales (*see* 19.537 *et seq.*), Victoria (*see* 28.37 *et seq.*), Queensland (*see* 22.732 *et seq.*), South Australia (*see* 25.492 *et seq.*), Western Australia (*see* 28.539 *et seq.*) and Tasmania (*see* 26.438 *et seq.*), were left with certain self-governing powers and preserved their own political institutions. Separate notes are added later as to certain details in the internal affairs of the individual states, but in the following account Australia will be considered substantially as a whole, in its aspect of a single national unit.

Population.—Public opinion in Australia has at different times condemned as unsatisfactory the rate of growth of the population both by natural increase and by immigration. The feeling that the natural increase of the population was not sufficient led in New South Wales to the appointment of the Birth Rate Royal Commission (1903). An outgrowth of that commission was a Federal Royal Commission on Secret Drugs and Cures which reported in 1907 and devoted much attention to the matter of artificial limitation of families. It was established fairly clearly by the first of these commissions that there was no natural cause predisposing to sterility in Australia, but that the desire for comfort conduced to a somewhat general artificial limitation of families. As a consequence of this commission some public opinion against the tendency to "race suicide" was aroused; and certain administrative measures were adopted by the Customs and Police departments which sought to lessen the facilities for artificial limitation of families. It is a coincidence, if not a case of cause and effect, that from 1903 "the natural increase" of population in the Commonwealth steadily improved until 1914 when, as a consequence of the World War, there was a very marked decline. Possibly a healthier public opinion following on the report of the Birth Rate Commission was in part responsible. Other possible contributory causes were a great increase in material prosperity following upon federation, and an influx of immigrants from lands where artificial limitation of families was not so much practised. The natural increase per 1,000 of mean population in 1906–10 was 15·93, which was higher than that of any European country, except The Netherlands and Bulgaria, and compared with 11·58 for England and Wales. But in 1915–9 it had fallen to 14·09. Australia has a low birth-rate and a very low death-rate. Taking a pre-war year the Australian death-rate of 10·4 compared with 14·5 for England and Wales, 30·0 for Russia and 19·3 for France.

In regard to immigration Australian public opinion has undergone a marked change, due in the main to a fuller appreciation of the danger of leaving the lonely outpost of the Empire in the South Pacific so bare of population. There was for many years a desire on the part of the exceedingly prosperous working people of Australia to keep out immigrants as much as possible, lest a rush of population should cause a reduction in the wage rate or a lowering of the conditions of life. That desire survives in some quarters, and is still a force to be reckoned with in a country where the Labour voters have the controlling power in politics. But it is being recognized, by Labour leaders as well as others, that a great access of population is necessary to the safety of the country and need not affect the general prosperity of a continent which has a little over 5,000,000, and has room, at a low estimate, for 100,000,000 people. In the beginning of Australian colonization state-aided immigration brought a great influx of people to Australia who otherwise would never have been able to afford the expenses of the long journey from Europe. Since 1906 the policy of state-aided immigration has been reëstablished in Australia, and was afterwards, though interrupted by the war, revived under Commonwealth direction.

On April 3 1911 the decennial census was taken in Australia, and the population ascertained to be 4,455,005, showing a rate of increase for the Federal decennium of 18·05% as against a rate of increase of 18·88 for the previous decennium. But whilst the annual rate of increase from 1901–6 was only 1·39% the annual rate of increase 1906–11 was 2·03. The year 1911 showed a total increase of 143,624, to which natural increase contributed 74,324 and Immigration 69,300, exceeding in one year by over 50% the total immigration gains of the previous ten years. Australia had thus "turned the corner" in regard to immigration, but the World War came as a

disturbing factor. During 1911–5 the Commonwealth gained 99,393 by immigration; during 1916–9, 24,016.

A preliminary census count of the census of 1921 gave the population of the Commonwealth as 5,419,702, an increase of 969,721 since 1911. In the individual states the figures were: New South Wales 2,096,393, increase 449,659; Victoria 1,530,114, increase 214,563; Queensland 755,573, increase 149,760; South Australia 494,867, increase 86,309; Western Australia 329,228, increase 47,114; Tasmania 213,527, increase 22,316.

The population included 2,751,781 males and 2,667,921 females. In Victoria there was an excess of females over males of 22,294. Full-blood aboriginals and the population of the territories are not included; the proportion of whites in the territories being insignificant. In accordance with these returns New South Wales would gain an extra seat in the House of Representatives, and Victoria lose one.

Social Conditions.—The Australian people are almost wholly British in character; 97·54 % of the total are of British origin, 1·21 % come from foreign European countries and 1·16 % from foreign non-European countries. The average standard of education is high and illiteracy almost unknown. The wage rate is generally high. The cost of living in Australia compares well with the cost in most civilized countries. In 1911 the statistician to the Commonwealth Government, Mr. G. H. Knibbs, instituted an enquiry into the cost of living. Taking four sets of family budgets, (a) of families with £200 a year and over, divided into families of four members and under four members, (b) of families with less than £200 a year, divided similarly, he found that the average percentage of income spent on housing was 13·70, on food 29·30, on clothing 12·72, on fuel and light 3·46, on "other items" (including amusements, thrift, etc.) 40·82 %. This last figure gives the best indication of general prosperity, *i.e.* of a substantial margin out of wages and salaries for non-essential outgoings. The percentage of income expenditure on food in working-class families in Australia was then 36 %, as compared with 57 % in the United Kingdom, and a general average of over 50 % in all other countries for which statistics were available. The cost of living showed in Australia a lower increase consequent upon the war than in most countries. For example, taking 174 as the index number for Sydney in 1913, that index number had risen to 268 (not much more than 50 %) in 1919.

The Australian birth-rate was 28·25 in 1913 and 23·78 in 1919. The percentage of illegitimate births to total births was 5·30 in 1919. The marriage rate (number of marriages per 1,000 of mean pop.) was 7·88 in 1919. The celebration of a marriage is more easily effected in Australia than in England. The facilities for divorce differ in various states, divorces being granted more readily in New South Wales and Victoria than in the other states. The total of Australian divorces in 1918 was 721.

A disquieting feature of Australian social life is the preponderance of the urban over the rural population. In South Australia more than one-half of the total population of the state (380,000 sq. m. in extent) is concentrated in the city of Adelaide. In Victoria 50 %, in New South Wales 41 % of the total population is in one city, and in the whole Commonwealth 42 % of the population is contained within six cities. The charm of the cities is great; the conditions in the "back country" are often hard. By cheap railway rates for the farmers' goods, by pushing such of the conveniences of civilization as are under state control as far forward as possible, and by other means, the states and the Commonwealth strive to counterbalance the call of the cities. But all effort seems to be in vain. The proportion of the urban to the total population is growing. In 1906 Sydney had 35 % of the total population of New South Wales, Melbourne had 42 % of the population of Victoria, and in the whole Commonwealth six cities held 35·49 % of the population. Now the proportions have greatly increased as seen above.

Public Health.—Though part of Australia is within the tropics there is practically no tropical disease, and there is an absence also of small-pox, hydrophobia and other diseases which are known in some parts of Europe. The death-rate from all causes in 1919 was 12·8. It is the lowest death-rate in the world except one. Lately there has been a betterment in regard to the infantile death-rate, which the hot summers ruling over the greater part of the Commonwealth make the chief cause of public health anxiety. In 1901 it stood at 103·61 per thousand, in 1919 at 69·21 per thousand. The Commonwealth Government pays a maternity bonus of £5 for every child born of a white woman resident in Australia. All the states have public health organizations to deal specially with infant welfare. Apart from infantile mortality, the chief foes to human life in Australia are tuberculosis, cancer, diseases of the heart and violence.

Education.—The Australian system of elementary education is free, compulsory, undenominational and usually secular. Secondary education is not free, but a generous system of bursaries makes education to the stage of a university degree available to the poorest in most states. There is also a good system of agricultural and technical colleges. In no state is denominational religion taught in the state schools; but private denominational schools exist, being maintained especially by the Roman Catholic Church.

Production and Industry.—The early stage of the federation was marked by a severe drought which checked for a time the development of prosperity. From 1905 the growth of prosperity was very great until the check given by the World War and another severe drought. The disturbance to economic conditions caused by that war takes away a great deal of the value of comparative figures. The following figures appear, as regards 1918, more favourable than they really are since the value of the £ sterling if expressed in goods had depreciated seriously since 1914. Total Commonwealth production: 1909 £174,195,000; 1913 £218,103,000; 1918 £298,669,000. Australia is chiefly a pastoral country and her pastoral products represent nearly a third of the total. Her exports alone from the pastoral industry in 1918–9 were valued at £57,624,791. Drought is still a serious enemy of this industry and the effects of recent droughts are reflected in the live-stock returns. In 1910 Australia had 92 million sheep. This fell to 69 millions in 1915, grew to 87 millions in 1918 and in 1919 fell to 84 millions. Cattle have done better and in 1919 had reached the highest record number, nearly 13 millions. Horses number 2½ millions. Agriculture, which in 1909 produced £41,000,000, in 1918 produced £58,000,000; and dairy produce and bee-farming, which in 1909 produced £15,000,000, in 1918 produced £34,000,000.

Mining keeps up a steady contribution to the national prosperity £23,000,000 in 1909, £26,000,000 in 1918. Gold production lately has been of decreasing, silver and copper of increasing importance. Coal has improved both in quantity raised and in price realized.

The manufacturing industries of Australia progress with each year, and it is clear that the British and American manufacturer must reckon on strong Australian competition in Pacific markets. In 1909 the manufacturing industries produced £40,000,000, in 1918 £75,000,000, (*i.e.*, added that value to raw materials).

In spite of the drain upon manhood and capital during the World War Australian industrial progress continued. Australia, under the influence of a strongly protective tariff, is entering each year on new fields of industry. In the iron and steel industry one new concern is producing 300,000 tons of steel a year. In shipbuilding Australian cost per ton produced is at the moment lower than that of Great Britain; in 1923 a protective duty of 25 % is to be imposed on British ships and of 30 % on foreign ships coming to trade in Australian waters. Australia is making a vigorous effort also to encourage the woollen textile industry, and there is mooted a project to give Federal Government assistance to raise a capital of £14,000,000 for textile mills. Easily accessible coal on the mainland and excellent water-power in Tasmania favour manufacturing development, and in many great industries the cost of labour in the Commonwealth is now less than in Great Britain. British manufacturers are in some notable cases establishing branch factories in Australia.

Forests and fisheries bring an amount of £7,000,000 to the Australian purse. But in neither case is there much progress. The timber resources are usually prodigally wasted; and until very recently there was no attempt at reforestation. The fisheries are not exploited in any systematic fashion, there being little or no deep-sea fishing or fish-curing. In both these matters, however, better things are promised in the future. In 1909 the Federal Government launched the "Endeavour," a vessel specially built to investigate and chart deep-sea fishing grounds. The "Endeavour" has since been engaged in the collection of information regarding the migration, feeding grounds, etc., of fish in the waters off the Australian coast, and it is hoped that the ultimate result will be the foundation of a great fishing industry. In 1912 the Australian Government offered bounties for Australian-cured fish. Nothing material resulted.

Trade and Commerce.—After federation the overseas trade of the Commonwealth increased rapidly. In 1901 the total was valued at £92,130,000; the recent figures have been:—

	Imports	*Exports*	*Total*	*Value per Inhabitant*
1911	£66,968,000	£79,482,000	£146,450,000	£32 12s. 3d.
1913	79,749,000	78,572,000	158,321,000	32 19 2
1919–20	98,607,000	148,565,000	247,172,000	47 2 1

The bulk of Australia's trade is with Great Britain, and a preferential tariff treatment of British imports is designed to help British as opposed to foreign trade. As a consequence of the war there was a very marked decline of British imports. The following figures of Australian imports will illustrate:—

Percentage from

Year	U.K.	British Poss'ns	All Foreign Countries (including U.S.A.)	U.S.A.
1901	59·47	11·22	29·31	13·80
1911	58·98	12·86	28·16	11·57
1919	37·10	22·15	40·75	27·29

This is chiefly a war result. Whilst British industry was to a large extent paralyzed, the United States and British possessions captured a bigger share of the Australian markets. But a slight (very slight) decline in British imports was noticeable before the war and after the granting of a preferential tariff. It is hardly reasonable to expect that British imports will ever go back fully to their old position in the Australian market. Australian exports to the United Kingdom showed a dwindling proportion of the total before the war. War regulations, confining the export of certain products to Great

Britain, temporarily arrested that decrease. Taking quinquennial periods from 1899 the first would show an average of 49·56 of exports to the United Kingdom, the second an average of 46·88, the third an average of 45·14. The war period 1914–9 showed an average of 53·46 %.

Australian trade with Asiatic countries develops steadily; exports to these countries were valued at £4,500,000 in 1901 and £19,000,000 in 1919.

Communications.—There has been a great railway development in Australia since the foundation of the Commonwealth. In 1901 the total railway mileage was 10,123; in 1919 it was 25,657. Nearly all the lines are owned by the Commonwealth, or the state Governments. In 1917 the Commonwealth-owned trans-Australian railway from Port Augusta to Kalgoorlie was opened, and the five capital cities of the mainland are now linked by rail. The distance between Perth and Brisbane, 3,474 m., is covered in less than six days. Another trans-Australian railway, crossing the continent from N. to S., is contemplated. Unfortunately there are four different gauges in use on Australian main lines in the various states: the question of the standardization of gauge is under consideration. The capital cost of the Commonwealth-owned railways had reached to £10,950,000 in 1919; revenue did not meet working expenses. The various state-owned railways by the same date had cost £213,971,000. On these working expenses absorbed 74·26 % of the gross revenue, and the net revenue gave a return of 3·01 % on the cost of construction. It has to be kept in mind that all the Commonwealth lines and some of the state lines are developmental railways built in advance of the settlement which would make them payable.

The Commonwealth adopted a policy of Government-owned shipping and of close control of private shipping. Up to 1912 Australia was content with navigation laws which sought to keep Australian coastal trade as much as possible for Australian ships, and insisted that all ships engaging in Australian coastal trade should observe Australian conditions in regard to wages, etc. Some very flourishing coastal shipping companies existed under these conditions. But war conditions affected very seriously the transport by sea of Australia's exports and, though relief to one class of producers came through the action of the British Government in buying for a number of years the whole wool crop in Australia, irrespective of when it could be shipped to Europe, there grew up the idea that the Commonwealth did not get as good shipping facilities as if she had her own Government-owned lines. In July 1916 Mr. Hughes, then Prime Minister, bought for the Commonwealth 15 steamers, each of about 7,000 tons, and a local building programme for 48 vessels was announced, with further programmes for building in Great Britain and America. Subsequently the local building programme was cancelled as regards 22 of the vessels; the local building programme for steel vessels (24) was continued, and six of them were running in 1921. In addition the Commonwealth Government had 18 ex-enemy steamers and one ex-enemy sailing vessel under its control. In Feb. 1917, a Commonwealth Shipping Board was set up to control all Commonwealth shipping matters; it has two committees, one for overseas trade with headquarters at Sydney, and one for interstate trade with headquarters at Melbourne. It has, *inter alia*, powers to divert privately-owned interstate shipping to overseas routes. The enterprise has not been a success either as regards the State ownership of shipping or the close State control of shipping, and there are indications that it may be abandoned. The total overseas shipping entered and cleared in Australia in 1913 was 10,601,948 tons, in 1918–9 6,180,486 tons. British ships were 73·53 % of the total in 1913 and 78·90 % in 1918–9. Two ports of Australia, Sydney and Melbourne, exceed in shipping tonnage entered the figures for all British ports except London and Liverpool.

Finance (*Public*).—The Commonwealth Government, which at its inception had a share of the customs and excise as its only great source of taxation, now collects customs and excise, land tax, probate duties, income tax, entertainments tax and special war taxes. Its revenue from taxation and from services was £21,741,000 in 1913–4 and £44,716,918 in 1918–9. The rate of revenue collected per head had increased from £4 9s. 3d. to £8 17s. 9d. The Australian, in addition to these Commonwealth taxes, has to pay state taxes. The average state taxation per head is £11 11s. 6d. and the total taxation per head £20 9s. 3d. Out of the customs and excise revenue collected by the Commonwealth a fixed sum of 25s. per head per year is paid to the states and the states impose their own income and land taxes, stamp duties and probate duties. Out of the Commonwealth revenue is met all defence votes and costs of Federal services.

The Commonwealth Government and the state Government both have power, and exercise it freely, to raise funds by public borrowing, but all the states except New South Wales admit some control on the part of the Commonwealth of their borrowings. The World War added hugely to Australia's debt. In 1919 the Commonwealth Government owed £326,000,000, of which £208,000,000 was held in Australia. The various states owed £396,000,000, of which £138,000,000, was held in Australia. The balance in each case was mainly held in the United Kingdom. Before the war it might be said that the bulk of the Australian debt, both Federal and state, was fully represented by revenue-producing assets such as railways. That could be said of the total (£337,000,000) in 1914 but not of the total in 1920 (£722,000,000), the difference being mostly represented by unproductive war expenditure. Of the state debts a total of about £35,000,000 was due to the Commonwealth Government, and that sum should be deducted from the £722,000,000 to calculate the actual debt load on the Australian people. In 1910 the Commonwealth Government by an amendment of the constitution was given power to take over all the state debts and consolidate them into one Federal issue. The power had not yet been exercised in 1921.

A Commonwealth bank of issue was opened in 1912. Its operations showed a credit balance of £1,922,000 in 1919. It transacts bank business and has a "Savings Bank" section. It had issued notes to the value of £57,000,000 by 1920 and held a gold reserve of 41·17 % against them.

Finance (*Private*).—There are 21 private banks trading in Australia, of which four have their head offices in London. In 1919 their paid-up capital totalled £35,696,000 and their reserved profits £23,543,000; their total liabilities £257,634,000 and their total assets £277,950,000. Depositors in savings banks numbered 2,945,000 (more than half the population) and the average deposit was £43 12s. 7d. or £25 per head of the whole population.

Government.—Under the Federal constitution the Commonwealth is governed by a governor-general appointed by the British Crown and acting on the advice of a Cabinet which is responsible to an Australian Parliament of two Houses. The Senate represents the states and is composed of six members from each state, elected for six years by the adults of the state voting *en masse* every three years to return three senators; the House of Representatives is about double the Senate in numbers (75), represents the people numerically, and is elected every three years by the adults of Australia voting in single-member electorates, which are approximately equal in population. The number from each state varies with the growth of population. The Australian Parliament can only act within the powers set forth in the constitution. The High Court is the final interpreter of that constitution and may veto any legislation, either of the states or of the Commonwealth, which is *ultra vires*.

Political History

The Commonwealth of Australia was formed in 1901 by the union of the six states of New South Wales, Victoria, Queensland, South Australia, Western Australia and Tasmania. The first Government of the Union was formed by Sir Edmund (then Mr.) Barton (born in N.S.W. 1849, d. 1920). Mr. Barton entered the N.S.W. Assembly as member for the university of Sydney in 1879. His enthusiasm was aroused for the cause of the Federation of Australia. After the death of Sir Henry Parkes he assumed the leadership of the Federal movement. The convention which framed the Federal constitution had recognized Mr. Barton's services by electing him as its leader. Now as Federal Prime Minister he called to his side the premiers of all the federating states; with one exception they responded; and this ministry of "all the talents" appealed to the people for support on a non-party platform.

The Early Parliaments, 1901–7.—The first Federal Parliament was however divided into three parties, that following Sir Edmund Barton, that following the Free Trade leader, Sir George Reid (born in Scotland in 1845, d. 1918), and the Labour party, under the leadership of one of the remarkable men of Australian public life, Mr. J. C. Watson. Born of poor Scottish parents in 1867 while on the voyage to Australia, Mr. Watson was in boyhood deprived of nearly all the advantages of education, but taught himself enough to become a printer. Sagacious, tactful, resolute, he came to the front in the Australian Labour movement and was elected first leader of the Federal Labour party. The success of the Labour party under his leadership at the polls was extraordinary. The first Parliament of the Commonwealth, divided as between the Government followers and Mr. Reid's Opposition party almost equally, had the Labour party holding the balance of power. This made a position of difficulty for the Government. The common-sense and moderation of Mr. Watson saved the situation to some extent. He gave a general support to the Government and assisted them in their most pressing tasks. Nevertheless the first Parliament was hampered by party fighting, the Opposition seeking to win the Labour party over to their side, and the Government being forced to postpone a good deal, to modify a good deal, in order to keep in office. Sir Edmund Barton was deeply disappointed. He had looked to a first

patriotic Parliament completing without any "scuffling on the steps of the temple"—to use his own phrase—the measures necessary for the stability of the Federation. He experienced a first Parliament in which party rancour was extraordinarily rife. He retired to accept a Federal judgeship, and Mr. Deakin (born in Victoria in 1856, d. 1919) took his place (Sept. 1903).

Mr. Alfred Deakin met the second Parliament of the Commonwealth in 1904 with his own following reduced, the following of the Labour party increased. In April 1904 Mr. Deakin went out of office and was succeeded by Mr. Watson. In Aug. of the same year Mr. Deakin gave his support temporarily to Mr. George Reid, and Mr. Reid's administration supplanted Mr. Watson's. This lasted through a long recess and a few days of parliamentary life, and in July 1905 Mr. Deakin came back to office with the support of Mr. Watson. Mr. Watson was at that time determined on resignation from political life as he could not keep pace with the extremist elements in the Labour party. But he was strongly convinced that a measure of tariff reform was necessary, and resolved to remain in Parliament until it was effected. The first Federal tariff had had to make concessions to Free Trade sentiment. The second tariff was completely protectionist, and introduced a new principle into Australian politics by granting a "preference" to British imports. At the third general election in 1907 the Labour party again improved its position, mostly at the expense of its allies.

Mr. Watson kept the leadership of the Labour party, and kept that party solidly behind Mr. Deakin, until the tariff was settled. Then he retired and Mr. Andrew Fisher took his place. Born in Scotland in 1862 Mr. Fisher was brought up as a coal-miner. He went to Queensland in 1885, entered the state Parliament and later the Federal Parliament. He had been included in Mr. Watson's Cabinet. Now, assuming the leadership, he very quickly gave Mr. Deakin notice to quit, and in 1908 formed his own administration. It lasted little more than six months. Mr. Deakin then formed a coalition with the remnants of the Free Trade Opposition, no longer led by Mr. George Reid but by Mr. Joseph Cook (born in England in 1860), and the Deakin-Cook administration came into office. One of its first acts was to send Mr. George Reid to London as a first High Commissioner for the Commonwealth; Mr. Reid, on assuming this office, accepted a knighthood. Mr. Cook, like Mr. Fisher, had been a miner. He entered the New South Wales Parliament as a Labour member, drifted away from his party and entered the Federal Parliament as a Free Trader. He now joined with Mr. Deakin to oust the Labour party from office, one ground of attack being their lack of proper sympathy with the cause of Imperial defence.

Australia's War Forebodings.—This was at the time of the European crisis over Austria's annexation of Bosnia-Herzegovina, when public interest throughout the British Empire was being stirred over the question of maintaining British supremacy at sea and of strengthening the hands of the Imperial Government in view of increasing international complications. New Zealand had promptly offered to provide a "Dreadnought" for the British navy. It was objected that Mr. Fisher had not done likewise. He claimed that his Imperial patriotism was not wanting, but that in his judgment more useful action could be taken by hurrying on with the creation of an Australian navy. This navy, he stated in a despatch to the British Government, would be organized and controlled by Australia in times of peace, but on the outbreak of war would automatically pass to the control of the British Admiralty. Amid bitter party wrangles the third Australian Parliament closed its life in Jan. 1910.

The general election of 1910 resulted in a victory for the Labour party under Mr. Fisher. The party captured a working majority in both the Senate and the House of Representatives. The decision which gave Australia's destinies completely into the hands of the Labour party (and that not the Labour party of Mr. Watson, but of Mr. Fisher—much more of a "party" man) was influenced very largely by negative considerations. The people disliked deeply the coalition of Mr. Deakin with Mr. Cook, who had before seemed to represent absolutely irreconcilable ideas in politics; and a vote for the Labour party was in many cases a vote of non-confidence in the coalition rather than actually an endorsement of Labour policy. An indication of this fact was given a little later, when the Labour Government (May 1911) submitted to a direct poll of the people certain amendments of the Federal constitution, without which it could not carry out its Labour policy. These amendments sought (*a*) to give the Commonwealth Parliament full power to legislate with respect to trade and commerce instead of the limited power it had under the constitution (the limitation stood in the way of Federal legislation dealing with the conditions of labour); (*b*) to give the Commonwealth Parliament full power over all trading corporations; (*c*) to give the Commonwealth Parliament specific power to deal with the wages and conditions of labour and with labour disputes; (*d*) to give the Commonwealth Parliament power to deal with all combinations and monopolies. A further proposed amendment of the constitution was to give the Commonwealth Parliament power to declare that any business was a "monopoly," and, following such declaration, to acquire it, paying on just terms for any property used in connexion with it. By a majority of about 250,000 votes in a total poll of about 1,155,000 votes the people declared against these amendments of the constitution. Thus a Labour Government was left in office without power to carry out its Labour policy.

The Fisher Government soon cleared itself very completely of any suspicion of a lack of earnestness regarding the defence of Australia and the Empire. In 1909, whilst Mr. Deakin was Prime Minister, an Act of Parliament had been passed enforcing military training on all able-bodied male citizens. This enactment of universal service had not been opposed by the Labour party. Indeed their criticism was that the system proposed to be enforced was not thorough enough; and the Government of the day promised that an expert from Great Britain should be asked to report on the system. Field-Marshal Viscount Kitchener accepted an invitation to visit Australia, and his report came before the Parliament of 1910 with a Labour Government in power. That Government not only accepted all his recommendations but in some cases crossed his "t's" and dotted his "i's." There was established a system of universal training for military defence which Lord Kitchener guaranteed as adequate and which the Fisher Government enforced against various protests with a resolute courage. In the matter of naval defence the Fisher Government was equally firm in dissociating itself from any faltering policy. A Commonwealth navy came into actual being as a fleet unit in 1913 when the battle cruiser "Australia" ("Dreadnought cruiser" type) and the light cruisers "Melbourne" and "Sydney" arrived in Australian waters. The same year the King laid the foundation-stone in London of Australia House, the splendid headquarters of the Commonwealth High Commissioner. A further step in the organization of the new nation was the appointment of the Inter-state Commission which, under the constitution, has power to adjudicate on and administer all laws relating to trade and commerce. It acts, in a sense, as a commercial High Court. Among its powers is that of preventing any preferential or discriminatory rates on the state railways.

The general elections in 1913 were unfavourable to the Fisher Government, and Mr. Joseph Cook took office with a majority in the House of Representatives but not in the Senate. His Government kept office under very difficult circumstances almost until the outbreak of the World War. On July 30 1914 the governor-general dissolved both Houses of Parliament, and in the general election that followed the Labour party won a majority both in the House of Representatives and in the Senate. A proposal to form a "national" Government representing all parties was not successful and Mr. Fisher formed his fourth administration in Sept. 1914. He gave up the Prime Ministership shortly afterwards to become High Commissioner in London and was succeeded by Mr. W. M. Hughes, his chief colleague. Mr. Hughes (born in Wales in 1864) on first coming to Australia was forced to many strange shifts to make a livelihood. But entering the N.S.W. Parliament as a Labour member of the "extremist" kind he soon proved himself to have ability and

fighting force of a rare order. Though subject to weak health, and later handicapped by deafness, he fought his way to the front rank by sheer grit. Seldom loved, he was always feared. Coming to the head of the Government in war-time he had fine scope for his combative genius. He earned bitter hatreds as well as generous praise in Europe and in his own country from 1914 to 1921.

Australia in the World War.—The gallant deeds of the Australian naval and military forces in the World War cannot be separated conveniently from the general history of the campaign, and there will be noted here only the political and civil developments. Australia entered the war with an enthusiasm of patriotism which obscured for a time any open sign of the fact that there was a section of the population which reflected closely the opinions of the Irish Nationalist party. About a third of the Australian population is of Irish origin; of this third the majority were (and are) more Australian than Irish in their national outlook, but a fraction of them have always inclined to give a first place to their Irish sympathies. Some dignitaries of the Roman Catholic hierarchy (which is largely Irish in origin and in education) have done much to encourage this fraction. As the war developed and an opposition to the British cause grew up in Ireland there was an echo of this in Australia. It was never sufficient to stand in the way of a whole-hearted prosecution of the war; nor did Irish Australians as a class refuse to take their share of the war's perils. But it was sufficient to prevent in 1916 and again in 1917 the passing of a referendum to enforce conscription for service overseas because it was able then to enlist on its side a genuine Australian feeling, partly made up of an objection to compulsion as under the circumstances supererogatory, and partly arising from personal hostility to Mr. Hughes.

A full understanding of the Australian character is needed to reconcile some apparently conflicting circumstances from 1914 to 1918. At the outbreak of the war Australia had a fleet in being which was at once transferred to the British Admiralty and did most useful work in the Pacific and in European waters. There was never a suggestion to tie it down to home waters nor to limit its best strategic use as determined by the British Admiralty. On the military side Australia had instituted a compulsory National Defence system for home defence, and this system was far enough advanced to be of some use in the recruiting of an Australian army. But the nation relied, as did Great Britain at the outset, on voluntary enlistment for overseas service. There was a magnificent response to the call for volunteers. By the end of the year Australian forces had seized the German Pacific possessions, troops had been offered for service abroad and 31,000 had left Australia for Egypt. In 1915 the Australian Expeditionary Force went through the unhappy Gallipoli campaign, and in 1916 was taking a distinguished part in France and in the Near East. The number of Australian divisions serving abroad represented a full quota of its manhood (five divisions to represent five million people).

When in 1916 conscription was proposed, that section of the Irish Australian people which, following the unhappy course of events in Ireland, had become hostile to Great Britain, opposed it (as did some other sections of the people). Their influence was sufficient to defeat this proposal, partly because it was understood that Mr. Hughes, the Prime Minister, would resign if his proposal were defeated, and many wished him to resign; but chiefly because the Australians felt that—to use their own vernacular—" they were doing a fair thing, anyhow." Since, in all, Australia sent 329,682 troops abroad, and they suffered 317,953 casualties (58,961 killed) and incurred war expenditure totalling £288,000,000 it cannot be said that there was any half-hearted Australian participation in the World War, though the result of injudicious political action was at one time to give that impression. Indeed the Australian national character came out of the test of the war very well. The Australian troops, the "Anzacs" as they came to be known from the initials A.N.Z.A.C. (Australia-New Zealand Army Corps), won a splendid reputation for courage and steadfastness. The Australian civil population bore without murmuring the heart-breaking losses of the Gallipoli expedition and the devastation—smaller as regards loss of life but more cruel in its needless sacrifice—of the outbreak of venereal disease following the location of their young troops near the stews of Cairo. When an Australian corps was formed in France under an Australian leader, Lt.-Gen. Sir John Monash, and did really conspicuous service in 1918, Australian pride knew no bounds. Lt.-Gen. Sir John Monash was one of the figures of the war. Born of Jewish parents at Melbourne 1865 he graduated at Melbourne University as a civil engineer. In 1887 he received a commission in the Australian militia as a lieutenant and thereafter took a passionate interest in military history and military science. At the outbreak of the war he was at first appointed military censor in Australia with the rank of colonel. Later he served throughout the Gallipoli campaign and in Egypt, and then as G.O.C. the Third Australian Division in France. Finally, in May 1918 he was given command of the Australian Corps. In this command he proved conspicuous ability and energy. His first operation at Hamel, July 4 1918, had the distinction of being made the subject of a special staff brochure by the British General Staff.

Sir John Monash tells his own story of the campaign in *The Australian Victories in France in 1918*. British military opinion of the Anzacs was described in "*G.H.Q.*" by "G.S.O."

Australia has made generous provision for her ex-service men. Pensions payable for total disability range from £2 2s. to £3 a week according to rank, with extra provision for a wife and all children under 16. A totally disabled soldier with wife and five children gets £3 17s. 6d. a week. Ex-soldiers and sailors are helped liberally to reëstablish themselves in civil life. Coöperating with the state Governments the Commonwealth Government has made available farming lands, and grants and loans for houses, working capital, etc.

Before the war German trade and industry had strong footholds in Australia, German shipping lines and German metal companies in particular. Indeed the Germans had almost a monopoly of the treatment of Australian base metal ores. On the outbreak of war, steps were taken to extirpate all German interests in Australia, and the legislation against enemy property, and for the internment of enemy subjects, was far more severe than in Great Britain at the time. The German had never been popular in Australia as a trader, and there was some reflection in the rigour of the special war legislation of old hostility to a people who came under the suspicion of " not playing the game."

Australia and the Peace.—Mr. Hughes as Prime Minister had during the war many political crises to face. His war attitude—which was ultra-vigorous—was very warmly approved in Great Britain by those who thought that Mr. Asquith's Government was somewhat slow in taking the necessary steps. This approval, expressed as it was with perhaps an excess of zeal, did not make things easier for Mr. Hughes with some Australians, who conceived the suspicion that he was "playing to the London gallery." No more deadly charge could be brought against a colonial politician than that. The Australian people are fervent in their Imperial loyalty, but they have always been jealous of " Downing Street interference " and somewhat suspicious of a London popularity for their leaders.

Internal dissensions forced a reconstruction of Mr. Hughes's Cabinet in Nov. 1916. Mr. Hughes and the Labour party drifted further apart and in 1917 he broke with them definitely, and, after an appeal to the country, formed a new ministry mainly from the ranks of the Opposition and including only three of his old Labour colleagues. A later appeal to the electors at the end of 1919 was destructive to the power of the Labour party (which was actively assisted by the " Irish party ") both in the Senate and the House of Representatives, but brought into being a new group, "the Country party," which represents chiefly agricultural interests. Mr. Hughes formed a new Government in Jan. 1918, but up to 1921 it had had a somewhat precarious existence and had been subject to serious internal dissensions. None of these home political troubles, however, diverted Mr. Hughes from his campaign against the German enemy and against British elements which he considered to be not earnest enough

in their antagonism to Germany. He was in London for a long term during the war, and in 1919 was in Paris as the Australian representative to the Peace Conference. One result of the World War had been to define the status of the great British dominions as that of really independent nations under the Crown. Mr. Hughes at the Peace Conference took full advantage of this new status, and vigorously fought for his idea of a peace much more punitive in terms to Germany than that actually agreed to. He was always in opposition to Mr. Wilson, often in opposition to Mr. Lloyd George. He wanted from Germany a full indemnity covering all war costs. He objected to any authority being granted to the League of Nations over ex-German territories in the Pacific which, he contended, should be straightforwardly annexed to Australia. Curiously enough, in this attitude Mr. Hughes was much more vigorously supported by a section of the British public than by his Australian constituents. He was acclaimed by many of these latter, but, returning to Australia, did not find the nation united under his leadership. His Cabinet was afterwards in a constant state of crisis, and early in 1021 it was rumoured that he would give up the Prime Ministership and come to London as High Commissioner, an office which Mr. Fisher had just vacated. But Mr. Hughes attended the Imperial Conference in London in June 1921 as Prime Minister.

The Constitution and the High Court.—The Federal constitution, in safeguarding the Federal power from trespass by the states and the power of the states from trespass by the Federation, necessarily set up a system of conservative check. But the full extent of that check was only understood when a High Court began to interpret various statutes in the light of the constitution. Already a considerable amount of the legislation of the Australian Parliament has been declared *ultra vires* by the High Court. Some of the decisions affected political issues so deeply that it was sought to amend the constitution so as to facilitate "Labour" legislation, but this effort failed. The power to amend the constitution is subject to many safeguards. A proposed amendment must first have the approval of an absolute majority of both Houses of Parliament; it is then submitted to a poll of the people, and to pass must secure (*a*) a majority of the total votes cast; (*b*) a majority of the votes cast in a majority of the states. If the three largest states voted "Yes" and the three smallest states voted "No," though the total Australian vote was "Yes," the proposed amendment would still fail.

In 1906 the Australian Parliament had passed an "Excise Act" which was intended to enforce what was called "the New Protection." A high protective duty had been placed on agricultural machinery, and at the same time an excise duty on the same machinery manufactured locally, with the provision that the excise duty should be remitted if the manufacturers paid "fair wages." On June 26 1908 the High Court declared this Act invalid, on the ground that it was not what it purported to be—a taxing Act, but rather an Act to regulate wages within a state, a thing which the Federal power was not competent to undertake under the constitution.

The first two Australian Parliaments devoted much time to discussing a Federal Industrial Arbitration Act, which included in its control state railway servants. This inclusion was nullified by a High Court decision that it was an unconstitutional interference by the Federal power with the affairs of the states. In the Trade Marks Act the Australian Parliament gave trade unions the right to register what is known in the United States as the "Union label," a mark showing that certain goods were manufactured by trade-union labour only. The Australian High Court (Aug. 1908) set this part of the statute aside on the ground that such a "Union label" was not a genuine trade mark, and the proposal to register it as a trade mark was really a subterfuge to assume control of labour conditions which were outside the province of the Commonwealth.

Not only Federal legislation but state legislation has been vetoed. An Arbitration Act in N.S.W. had sought to give the widest powers of regulating industrial disputes. In a series of five judgments the High Court gave such a strict interpretation to the provisions of that Act that it was more than half destroyed. (The High Court is the only court of appeal in cases affecting the constitution, and is with the Privy Council an alternative court of appeal in all other cases.)

In 1911, and again in 1913, 1915 and 1919, proposals were submitted to referenda for amendments of the Federal constitution which would legalize for the future the Labour legislation which the High Court had vetoed: all were rejected. The Australian constitution, as interpreted by the High Court, remains a barrier against any great development of socialistic enterprise on the part of the Commonwealth Government. In its working the Australian constitution [illegible] proved the most conservative instrument of Government w[illegible] British Empire.

Industrial Disputes.—Australia has elaborate machinery in Commonwealth and state Arbitration Courts for the settlement of industrial disputes without strikes. But strikes are very frequent and do grave damage to the development of the country. They are directed against the state as an employer as well as against private employers. The strike on the Victorian state railways in 1903 was followed in 1908 by a strike on the Sydney state tramways. Both of these strikes against state employers failed. New South Wales in 1908 altered its industrial arbitration system, and, this alteration being resented by the trade unions, various strikes followed. The next year (1909) more serious strikes broke out on the Broken Hill (N.S.W.) silver-mining and the Newcastle (N.S.W.) coal-mining fields. Stern measures were taken by the New South Wales Government to repress these strikes, and the leaders in the strike movement were arrested and some of them punished with imprisonment. In 1910 there were strikes of tramway employees at Perth (W. Aus.) and of transport workers at Adelaide (S. Aus.). In 1912 the tramway employees of Brisbane came out on strike because of a slight grievance against their employers (a private company). The leaders fomented a sympathetic strike on "syndicalist" lines, calling out the workers in every industry with the avowed object of preventing all business. Serious riots accompanied the strike. The state Government acted with decision, and the strike disorders were crushed and the syndicalist movement defeated.

The World War did not stop strikes. In 1914 and again in 1916 there were serious coal strikes. Working-days lost through strikes in successive years were: 1913, 623,000; 1914, 1,090,000; 1915, 583,000; 1916, 1,678,000; 1917, 4,599,000; 1918, 580,000; 1919, 5,652,000. The losses in wages through strikes during the period 1913–9 were estimated at £8,500,000—big figures for a country of which the total pop. is only 5,000,000. The statistics as to the methods of settling strikes force the conclusion that the legal industrial arbitration machinery is not effective—of 460 disputes settled in 1919 only 38 were settled by the state Arbitration Courts and nine by the Commonwealth Arbitration Courts.

The Tariff.—The Australian tariff is protective, with a rebate on some of its rates for British productions. The first tariff passed in 1901 was mildly protective; the second passed in 1908 was more stringently protective but made a "preference" concession to British manufacture. Successive changes since have been always in the direction of higher protection, keeping the Imperial preferential element, and (in an Act of 1920) extending it to other dominions of the British Crown. In the attempt to quicken the growth of Australian production a system of bounties was instituted by legislation in 1907, 1912 and 1918. Bounties are paid on the local production of certain agricultural products (cotton, rice, coffee, cigar tobacco leaf, dried fruits, fibres, oil); of preserved fish; of iron and steel; of shale oils; of sugar, if grown by white labour; of combed wool or wool "tops" exported.

Defence.—When the Commonwealth Government took over the defence of Australia from the states in 1901 there existed for land defence in the various states very small forces of regular troops, used as instructional cadres and as garrisons for the forts; small forces of militia, enlisted under a voluntary system and paid for about 16 days of drill and camp training a year; further small forces of volunteers, not paid at all, and giving usually but scanty time to training. The total of these forces was 25,873, of whom a proportion could be counted as efficient. Naval defence, apart from the existence of various small craft, was entrusted to the British navy, and a yearly subsidy (up to £126,000) was paid to the British Admiralty on condition that a fleet of a certain strength was maintained in Australian waters and certain facilities given to Australians wishing to enter the naval service.

At first the Federation did little to disturb these arrangements. The fleet subsidy was continued and extended. The military forces were taken over as they were. But the Defence Act of 1903 gave indication of a new spirit. It made provision for the enlistment of all able-bodied males for defence service in case of war. An amendment proposed by Mr. W. M. Hughes, then one of the leading members of the Labour party, that this universal obligation to military service should be accompanied by a universal obligation to training for service, was rejected. But it was inevitable that in time the one should follow the other. Mr. Hughes constituted himself the parliamentary champion of compulsory training for service, and—assisted outside the House by the National Defence League, of which Col. Gerald Campbell, a volunteer officer of distinction, was the moving spirit—eventually secured the acceptance of the principle.

A series of Acts from 1909 to 1918 gave Australia a military system under which, with few exceptions, the whole manhood of the country is trained to the use of arms. Under this system, at the age of 12, a boy must begin training (chiefly physical culture) as a junior cadet. Training as a senior cadet begins at 14 and lasts until 18; it comprises drills equivalent to 16 full days a year. At the age of 18 the obligation to undergo adult training begins, and lasts until the age of 26. This adult training consists of the equivalent of 16 full days' drilling a year, of which not less than eight shall be in a camp of continuous training. In the case of the artillery and the engineers the training extends to 25 days a year, of which not less than 17 must be in camp. There are certain exceptions, including one making provision for those who have conscientious scruples against bearing arms; these however are trained for the hospital and ambulance services. The thinness of the population in some districts

forces another class of exemption; the residents of the far "Outback" cannot be economically mobilized for training, and for the present are left out of the scheme. A Staff College in the Federal Territory is provided for the training of officers, and its organization is on severely practical lines. Cadets are accepted after examination. The whole cost of their college training is borne by the army estimates, and parents are forbidden to supplement the messing allowance by private pocket-money. Even railway fares to and from the college when cadets go on holiday leave are paid by the Government, as are also all costs of uniform and equipment. A severe but not unwholesome discipline is exacted; the drinking of alcoholic liquors and cigarette smoking are both forbidden in the college. The normal course lasts four years and is followed by a tour of duty in England or in India, after which graduates are available for staff appointments in Australia and New Zealand (the latter dominion shares in the carrying on of the college). During the World War the course at the Staff College was somewhat modified and 158 cadets were specially graduated for service at the front. The college provides for 150 cadets.

As, after training, the citizen soldier passes into a reserve, the potential military resources of the Commonwealth in the future are only to be calculated by the total number of males of "military age," minus those who had been exempted from training. On the basis of the present population there would be 366,000 males between the ages of 18 and 26; 330,000 between 26 and 35, and a further 614,000 between 35 and 60. Exemptions, at a broad guess, might be 25%. The organization of the establishment is at present 90 squadrons of light horse, 52 batteries of field artillery, 93 battalions of infantry, and a due proportion of engineers and army service corps.

In regard to naval defence there was strong criticism of the subsidy policy at the very outset of the Federation. But that policy was warmly supported by the British Admiralty and the Imperial Defence Committee; and the impression was given that the only alternative to an Australian cash subsidy towards the British navy was no coöperation at all in the naval defence of the Empire. Indeed the early advocates of an Australian navy were met in their own country with charges of disloyalty to the Mother Country. But Australian public opinion steadily hardened on the subject. The British Admiralty was ultimately converted, in part at least. On Dec. 19 1907 Mr. Deakin, as Prime Minister of Australia, outlined a scheme by which Australia would devote the amount of the naval subsidy, then £200,000 a year, to the building of an Australian fleet, under the control of the Commonwealth Government but trained to cooperate with the British navy.

The general anxiety as to the European situation in 1909 made the subject of Imperial defence of the first importance. Australia was represented at an Imperial Defence Conference in 1909, which showed a remarkable change of opinion on the subject of "local navies" on the part of the British Admiralty. They brought down to the Conference, as a substitute for an Australian subsidy to the British navy, a proposal for the building of an independent Australian fleet unit with the help of a British Treasury subsidy of £250,000. The Australian Government adopted the scheme in its entirety, except that it refused to accept the subsidy and decided to put the whole cost on the Australian taxpayer. Under this scheme Australia was to provide a fleet unit with a "Dreadnought" cruiser as its chief vessel.

In March 1911, at the request of the Australian Government, and at the close of a visit to Australia, Admiral Sir Reginald Henderson reported on the naval needs of the Commonwealth. His report was accepted, and it represents the present aim of Australian naval defence. In 1919 Admiral of the Fleet Lord Jellicoe visited Australia to advise the Commonwealth as to their naval programme in the light of the lessons of the war. In 1921 a special conference was held at Singapore to consider the Pacific naval position. It was announced by the British Admiralty early in 1921 that British naval policy (especially in regard to a battleship programme) would not be finally decided upon until after discussion with the dominions. Thus the wheel had come full circle from the British Admiralty attitude of 1907, which discountenanced any dominion naval action except a financial support for the British navy, to the decision that the British naval programme must not be finally settled without consulting the dominions.

The Australian naval organization has a naval college at Jervis Bay for the education of naval officers. The system follows that of Great Britain exactly except that all expenses of the cadets are met by the Commonwealth Government and parents pay no fees. There is also a training-ship at Sydney for the training of other ranks. The Australian navy is in charge, for the Empire, of the S. Pacific naval station. It has a fleet of 30 surface warships headed by the battle cruiser "Australia," six submarines, and various auxiliaries.

Australia's defence expenditure (naval and military) in 1905 was less than £1,000,000. In 1918–9 it was £87,270,000, and the estimates for 1919–20 were for £81,029,000.

The visit of the Prince of Wales to Australia in 1920 was marked by the most cordial demonstrations of loyalty and personal affection. An effort was made by the Irish party and an extremist Labour section to strike a discordant note. It failed completely. The Australian soldiers in France had been won by the Prince's qualities of courage, dutifulness and charm to what may be called without exaggeration a devoted admiration. They gave the lead to Australian public sentiment in the welcome of the royal visitor.

New South Wales

The area of New South Wales is computed at 309,472 square miles. The state has progressed rapidly since federation. The pop. in 1900 was 1,364,590 and in 1919 2,002,631. In 1908 New South Wales reëstablished a system of state-aided immigration. The city of Sydney has shown a remarkable growth since federation, and in 1912 a "Million Club" was formed to foster the growth of the city to 1,000,000 inhabitants. Pop. (1921) 828,700.

Politically, New South Wales was the original headquarters of the Australian Labour party; its state Parliament is usually controlled by the Labour party and the Premier in 1921 was the Hon. John Storey, leader of the Labour party. At the time of the Union, New South Wales was the centre of anti-federation, and its hesitancy to throw in its lot with the other states caused some delay in realizing the Union. A certain anti-federal spirit persists, and is shown in the fact that this state stands out from the Federal control of its borrowings. No state has benefited more from the Union, the effect of which tends to group most of the great industries of the Commonwealth around the New South Wales coal-fields. A recent development of great importance was the foundation of steel manufacture at Newcastle.

Besides Sydney (the greatest port of Australia and the chief entrepôt for the American, the Asiatic and the Pacific trade), New South Wales has notable cities in Newcastle—the centre of the coal-mining industry—Broken Hill, a great silver, zinc and lead-mining town in the far W. of the state; Tamworth, Bathurst, Goulburn, Wagga and Albury, pastoral and agricultural centres.

The governor in 1921 was Sir Walter Davidson.

Victoria

Since Federation the pop. increased from 1,197,206 to 1,495,938 (1919). State-aided immigration was reëstablished in 1908 and a vigorous policy of closer settlement has been adopted. Before the Union Victoria had established by a high protective tariff a lead in the manufacturing industries. That lead has now passed to New South Wales. Victoria is, however, developing with energy her agricultural interests, and has lately made good progress with intensive fruit-growing on the banks of the river Murray. The area under all crops in 1919 was 3,942,000 acres. The state has been more stable in its politics than most of its neighbours and is the centre of Australian Conservatism. As temporary seat of the Commonwealth Government, Melbourne (pop. 743,000), the capital of Victoria, is also the political capital of Australia, and the housing of the chief Federal departments there has given some impetus to the city's growth. Since the inauguration of the Federation it has been improved greatly in appearance by a scheme of tree decoration applied to the river banks and the chief streets.

The governor in 1921 was the Earl of Stradbroke.

South Australia

S. Australia has an area of 380,070 sq.m. and a pop., in 1919, of 468,194, having been relieved of the care of the Northern Territory. The state is facing the development of its "dry-belt," where wheat-growing has been found to be possible with a very low average rainfall. In 1901 the area under wheat was 1,743,452, in 1919 2,186,349 acres.

In politics South Australia has always been very progressive in spirit. It was the first state to enfranchise women, and most of the "social reform" legislation of Australia originated here.

The governor in 1921 was Sir Archibald William Weigall.

Western Australia

The pop. was 331,660 in 1919. The state has had for many years a system of state-aided immigration. The backwardness in development of this, the largest of the states, is being met by a vigorous land settlement policy. In 1920 the state had 1,605,000 ac. under crop, mostly wheat. The gold yield is dwindling. In 1918 it was 876,512 oz. compared with 1,595,270 oz. in 1909. But W. Australia is still by far the largest producer of gold in Australia.

The governor in 1921 was Sir Francis Newdigate Newdegate.

Queensland

The pop. was 725,220 in 1919; the state has progressed greatly since federation. Alone among the Australian states it develops its railways from several maritime centres instead of from the one capital city. The sugar industry is a great source of Queensland wealth, and some anxiety was formerly felt as to whether the "white labour" policy of the Commonwealth would not ruin this industry. That anxiety no longer exists.

Politically the state is one of the strongholds of the Labour party, and during 1920 its Labour Government was strongly criticized in Great Britain for passing an Act which was regarded as repudiating the conditions under which British capital had been advanced for pastoral development.

The governor in 1921 was Sir Matthew Nathan.

TASMANIA

With a very mild climate, in which drought is unknown, Tasmania (pop. in 1919, 216,757) is destined to be the garden, orchard and small-culture farm of the mainland. A new source of wealth now being developed is that of the production of electricity from water-power. A great industrial future is promised from the utilization of the Great Lake water-power, and there has been talk even of carrying electric power by cables across to the mainland.

The governor in 1921 was Sir William Allardyce. (F. F.)

AUSTRALIAN LITERATURE.—Australia's beginning was from a literary standpoint unfortunate. The primitive aborigines had no history and no legendary lore which, finding expression through some of the first colonists, might have added to the world's stock of romance. The exploring of the continent—the siege of the Blue Mountains with their baffling natural fortifications, the conquest of the great fastnesses of the sun on the dry inland plains—might have inspired an epic, but no one of the explorers nor of their contemporaries attempted more than a bare record. The sordid convict era inspired one book—*For the Term of his Natural Life* (1874), by Marcus Clarke—which is made notable by its subject rather than its treatment. The bushranging era inspired another—*Robbery Under Arms* (1888), by "Rolf Boldrewood" (T. A. Browne)—of which the same may be said. Those are the two master works of early Australian letters. Yet neither is distinctively Australian in the sense of showing a different outlook on life or a different sense of literary values, to that of the average contemporary English writer. The same may be said of the poems of Adam Lindsay Gordon, who wrote in Australia of Australian subjects from the standpoint of an English squire.

At a later epoch, when there was less promising material, there came the beginning of a characteristic Australian literature giving great promise which as yet has not been fulfilled. The people—bred from the wilder and more enterprising of English, Scottish and Irish stock, responding to the influence of the bountiful, sometimes fierce, sunshine, and to conditions of life which are singularly free from any bonds of convention and tend to the levelling of social conditions—have departed somewhat from the home type. They are gay and debonair, whilst a little inclined to be cynical, irreverent and vainglorious; enduring and brave, even to the point of being somewhat ruthless. The qualities of these new people, the Australians, begin to show in their literature, which is as yet more impressive in quantity than in quality. There are at least one hundred minor poets of some skill and originality of thought in Australia (with five million inhabitants), and nearly that number of prose writers of distinction—all showing to the close observer some signs to distinguish them from writers of the same class in Great Britain and in America. A hedonistic joy in life, a disrespect for authority, a wit tinged with cruelty, a freakish humour founded on wild exaggeration—those are the qualities which outcrop most often in exploring the fields of contemporary Australian literature. There is to be found, too, a tinge of mystic melancholy, a sense of bitterness—a loving bitterness—inspired by the harsh realities of life in the "bush" where Nature makes great demands on human endurance before permitting her conquest, but enslaves her wooers by her very cruelty.

This modern Australian literature owed very much to one man—J. F. Archibald (1858–1919). He was of partly Scottish, partly Irish, partly French forbears, with a touch of Semitic blood. Editor for a quarter of a century of a notable Australian paper, he made it his mission to encourage young Australians to write of the life that was peculiar to Australia. He was a wit with a fine *flair* for a phrase; a sentimental cynic; and passionately Australian. Mainly under his aegis there came forward a young school of writers which included Henry Hertzberg Lawson (b. 1867), who has given us true stories and verse faithful, sometimes terrible, glimpses of the "bush"; Andrew Barton ("Banjo") Paterson (b. 1864), a singer of the rackety, horsey life of Australian sheep stations; George Louis Becke (1848–1913), who pictured South Sea Island life; Arthur Hoey Davis ("Steele Rudd," b. 1868), who writes broadly comic and yet sympathetic studies of life on the small farms of Australia; Roderic Quinn (b. 1869), and the late Victor Daley (both of Irish extraction and giving in their verse two different and yet both characteristically Australian modifications of Celtic melancholy); Edwin James Brady (b. 1869), writer of sea songs; Ethel Turner (Mrs. H. R. Curlewis, b. 1872), English-born but Australian by education, a graceful novelist of Australian childhood; Bernard O'Dowd (b. 1866); Barbara Baynton, Mary Gaunt, James Francis Dwyer (b. 1874) and many others. Some of these owed much, some little, directly to Archibald and his newspaper. But without a doubt he was the chief founder of a new Australian literary movement.

Within the decade 1910–20 there was very little that was characteristically Australian in the literary product of the southern continent. An exception must be made for *The Sentimental Bloke*, by C. J. Dennis, a collection of verse which showed original qualities of humour and sentiment. A distinctively Australian literary magazine, *The Lone Hand*, faded away after a period of apparently vigorous life.

Australian letters suffer from diffused energy. There are numberless writers of some ability, but no commanding figures. The future holds out a hope of Australian work of the first rank, inspired perhaps by the "bush"—the mysterious Neolithic-age forests, hills and plains—perhaps by the giant work of the early explorers, perhaps by the extremely fluid social conditions of a young country full of self-confidence as it grapples with the old, old problems of civilization.

The Australian newspaper press reproduces with close fidelity British press characteristics. The Melbourne morning journals, the *Age* and the *Argus*, follow traditions which in the British islands survive only in Scotland and the provinces; the Sydney morning journals, the *Herald* and the *Telegraph*, are somewhat more new-fashioned, and are comparable with their London contemporaries. Practically all Australian papers record fully not only the doings of their own parliamentary and municipal bodies but also British political history and foreign affairs. A new note of progress has come into Australian journalism since 1910 by the foundation of a cable news agency as a rival to the old agency which for many years had a monopoly of foreign news service. (F. F.)

AUSTRIA, LOWER (*see* 3.1).—Lower Austria is bordered on the E. and N. by Hungary and Czechoslovakia; on the W. by Czechoslovakia and Upper Austria and on the S. by Styria. As the result of the losses of 1919 (Stadt-Felsberg and other places), Lower Austria extends over an area of about 7,639 sq. m. only. The pop. of the present Lower Austria was in 1910 3,525,094, but in 1920 it was reckoned at only 3,313,155 (434 per sq. m.). In 1910, 91·68% of the population were Roman Catholics, 5·26% Jews, 2·64% Evangelicals and most of the remainder belonged to the orthodox Greek faith. For administrative purposes, this territory is divided into 23 districts and 3 cities, the municipalities of which are autonomous, viz:—Vienna, the capital, pop. (1920) 1,842,005; Wiener-Neustadt 35,000, and Waidhofen an der Ybbs 4,740. Other important towns are: Baden (pop. 8,698; and with its suburbs 21,095); Bruck an der Leitha 6,007; Schwechat 8,528; Korneuburg 7,736; Stockerau 10,324; Krems 13,595; Mödling 17,704; Neunkirchen 10,759; St. Pölten 23,061; Klosterneuburg 13,431.

Of the total area 96·3% is productive, and of the productive area 45·3% is arable, 35·5% forestal, 13·6% gardens and meadows, 3·7% grazing-lands and 1·9% vineyards. The neighbourhood of Vorarlberg in Lower Austria is the chief industrial district of the new Austrian Republic.

The Wiener-Neustadt-Vienna canal is now no longer used. At Grünbach, near by, are the only big coal-mines now belonging to Austria. In the hill country to the E. are lignite deposits, now mostly on Hungarian territory, but partly in the Burgenland. Korneuburg is proposed as the starting-point of the projected Danube-Oder canal.

AUSTRIA, UPPER (*see* 3.2).—Pop. in 1910, 853,006; in 1920, 857,234 (185 to the sq. m.). For administrative purposes, this territory is divided into 15 districts and two autonomous municipalities, viz:—Linz, the capital (pop. 93,473) and Steyr (pop. 20,234). Other important places are: Wels (pop. 15,427); Bad Ischl (pop. 9,695—the town itself 2,291); Gmunden

(pop. 19,604—the town itself 6,411). These figures are from the census of 1920. In 1900, 92·1% of the soil was productive and the productive areas included 38·1% arable; 20·1% meadow; 2·7% grazing land; 36·9% forestal and 2·2% gardens. The salt production of Upper Austria forms nearly 60% of the whole Austrian output.

Urfahr is now incorporated with Linz. The Pöstlingberg (1,762 ft.), a favourite resort, is connected with Linz by mountain railway. The pop. of Steyr increased by only 150 between 1900 and 1910 because of a decline in the iron industry, and the increase afterwards was due to the opening during the World War of a munitions factory which was later converted into engineering works.

AUSTRIAN EMPIRE, 1908–18.—The external designation of the state "unofficially known as Austria" (*see* 3.2) was for a long time unsettled.[1] The official name since 1867 for the Austrian half of the Austro-Hungarian Monarchy, as including the Habsburg possessions W. of the river Leitha, was "the Kingdoms and Territories represented in the Reichsrat" (*Die im Reichsrate vertretenen Königsreiche und Länder*). It was cumbrous and but little calculated to arouse patriotic sentiments in its citizens. In the style of the Government offices this mass of territories was known as "Cisleithania." But the population was accustomed to talk of an Austrian Empire and of the Austrian Emperor, neither of which designations was quite happy or accurate. It was not till the World War that the dynasty felt the necessity for giving this group of countries a definite name and state arms of its own (as was done on Oct. 10 1915), the term "Austrian Empire" being adopted with the motive of giving "precise expression to the political unity of the Austrian territories" and "displaying tangibly the Austrian state as a unity." This proceeding might be compared to a death-bed baptism.

Nationalities.—The Austrian state had from its first origins always had a self-imposed political mission; its very name of origin, *Ostmark* (The Eastern March), marked it geographically as a bulwark, a gate-keeper, to defend Europe on the W. against encroachments from the E. From this original task arose a second, that of affording shelter to the fragments of peoples heaped together in inextricable confusion in this corner of the earth. With a few exceptions (Poland, Bosnia) it was through their free will that the Empire had come into being. The external legal forms of the union were marriages, inheritance and election; it was essentially the self-determination of the nations which brought them together. For 500 years Austria had fulfilled this double task fairly adequately; but in its third task, that of turning a mechanical combination into an intimate union, a symbiosis of the nationalities, the State failed. If it had achieved this as well, it would have given a model solution of the most difficult European problem; for Austria was Europe in miniature. There was no lack of attempts to do so; the methods varied, experiments were made as on a subject for vivisection; the object of the experiment suffers under it, but the method is perfected step by step.

Till late in the 18th century the nationality question remained untouched, and the Austrian peoples got on well with one another. Maria Theresa and Joseph II. were the first who thought it desirable to form these nationalities into a uniform nation coextensive with the state. The attempt failed, and the nationalities became self-conscious and split apart. The next stage was to take *one* people and train it as the representative *par excellence* of the State idea; and this people could only be the Germans. This attempt also failed; for the Germans were numerically too weak, and not vigorous enough in their methods (Bach period, 1850–60). A third experiment took the form of distributing over many backs a burden too heavy for one. In 1867 the Magyars accepted with alacrity this rôle in Hungary, the eastern half of the Dual Monarchy, while in the Cisleithanian territories the coöperation of the Poles was also sought. But this way too had to be given up, since even the smallest nationality would not allow itself to be absorbed, and during Taaffe's administration (1878) the idea came into favour of treating each nationality, and allowing it to grow up, according to its own idiosyncrasies; they were only to be restricted so far as the unity of the state rendered it absolutely necessary. What Austria desired to be was a state at once conciliatory and just, and it opposed no national demand which did not overstep the limits of state security; but this loosing of bonds unchained at the same time a number of national passions before which the state retired step by step.

As to the details, the following observations[2] may be made for the last phase of the empire which expired in 1918. The *Germans* had for long past given up all efforts at Germanization; their watchword was "maintenance of the national *status quo*"—that is to say, not an aggressive but a defensive principle. It was in Bohemia that they championed the principle most openly, where they were striving for national separation and protection against the Czechs of the territories which they had inhabited since the Middle Ages. The Germans of the Alpine lands were less ready to carry out the same principle in Tirol and the regions leading down to the Adriatic. The divided policy of the Germans led on all sides to their failure. In Tirol they lost even purely German territories; they were pressed back from the Adriatic; and in the lands S. of the Sudetic Mountains they were brought under a Czech national state, which inherited, with them, the problem of nationality.

The *Czechs* came under the sceptre of the Habsburgs after the battle with the Turks at Mohacs (1526), through an inheritance treaty confirmed by the vote of their Estates; an unsuccessful rebellion which they made in 1621 against the ruling house as protagonist of the counter-Reformation, brought them under the power of a ruthless conqueror, who wished to crush both their faith and their national independence. The reign of terror which followed the battle of the White Mountain was intended to remove all possibility of a fresh rising in the future. The Czechs rightly refer to this period 300 years ago when they describe themselves as a once oppressed nation. But in more recent times the position was different; the conquered race recovered, and a learned work, *Die bohmische Nation*, published in 1916 by the intellectual leaders of the nation, enlightens us as to their position. Dr. V. Zdeako Tobolka, leader of the "Young Czechs" (*i.e.* the party which had frustrated the efforts of the Old Czechs for a reconciliation with the Germans) produced this magnificent work in collaboration with 22 professors, artists, industrial leaders and writers of Czech nationality, supported by a national subsidy; it can therefore be accepted as a trustworthy Czech autobiography. This comprehensive book describes the collective life of the "Bohemian" people, as the Czechs called themselves in contrast to their present appellation of the Czechoslovak state. It describes its material development, "its physical constitution and warlike prowess," of which they make a special boast, and after that its intellectual progress. In the sphere of education attention is drawn to the fact that 96·69% of the population of the Sudetic territories can both read *and* write: "Our education is, next to the German, the best organized and stands decidedly the highest" (p. 122). Next follow chapters on the literary renaissance of the nation, its progress in art, mathematics, chemistry and natural science; the magnificent development of agriculture, modern industry, commerce and finance; and in particular its flourishing self-government, "which will be exercised in the fullest freedom," and in which "the communal organization embodies in the highest degree the conception of self-government" (p. 234), and "the independent sphere of activity unlimited in its fundamental principle" (p. 235) in that "State control is exercised seldom and discreetly" (p. 236). "The control which is exercised over the land is in Czech hands since we possess a majority; the territorial authorities for the greater part belong to our nation" (p. 242). The influence of German culture is also remembered with gratitude. Of Palacky, the father of the nation, it says: "It was under the influence of German culture that Palacky was able to give a firm foundation to this conscious Bohemian ideal of his. To cut oneself off from external cultural influences, especially from German ones, he declared to be a mistake." Besides mentioning the encouragement bestowed by leading Germans like Goethe, Herder, Raumer, etc., on Czech poets and scholars, the book gives an appreciative account of the Emperor Joseph. The article by Jakubel on "the literary renaissance" says: "The Prague theatre, which had vegetated miserably up to now, developed under the reign of Joseph II. into a powerful instrument of culture. Joseph's

[1] For HUNGARY, as the other constitutional half of the old Austro-Hungarian Monarchy, see the separate article under that heading; also BOSNIA-HERZEGOVINA, and the articles on the different "succession states" which were formed on the break-up of the monarchy in 1918. As a matter of convenience, the account of Austro-Hungarian foreign policy (*i.e.* the Dual Monarchy as a whole) in 1909–18, dealing, from the Austrian standpoint, with the political developments resulting in the World War, is included as a final section under the present heading. The Austro-Hungarian army is dealt with under ARMY. (Ed. *E. B.*)

[2] As elsewhere throughout this article, the point of view is that of a fair-minded Austrian historian. (Ed. *E. B.*)

enlightened despotism preserved to the Bohemian people at one stroke an astonishing number of distinguished and progressive spirits." In Prof. Kadner's article on education we read: "A new organization was first created by the famous May education laws of 1869. It was the liberal-minded Germans who were instrumental in the first place in getting them passed; while the Slavs from the beginning took up—to their own disadvantage—a hostile or at least passive attitude towards the establishment of these laws." It should be difficult, after the copious details of this autobiography *de luxe* of the Czech nation in the year 1916, to speak of it historically as an "oppressed" nation of Austria.

The *Poles* were, together with the Ruthenians, the youngest Austrian nation; the repeated partitions of Poland since the 18th century brought them unwillingly under Austrian rule. After a short period of German government, which was highly beneficial to the country, Galicia received after the Constitution of 1867 an exceptional position which was gradually consolidated; the German officials were removed, and the Polish members in the Reichsrat (who represented 71 votes) held the balance between the parties, which brought Galicia, without any effort, great financial advantages at the cost of the other Crown territories. Up to the World War there was actually no articulate irredentism among the Austrian Poles; they were more contented than their co-nationals in Russia and Germany, and this explains their attitude of vacillation and indecision during a long period of the war.

Ruthenians.—Just as the Czechs had a majority in Bohemia, so had the Poles in Galicia; and they used their strength against the Ruthenians. The Austrian Government being largely dependent upon the parliamentary aid of the Poles, could not stand out against them much on account of the far-reaching autonomy of the Galician Territorial Government. And so Russophil agitation found a fruitful soil, especially among the clergy and intellectuals. The Ruthenians, who were loyal to the empire, drew attention to the small degree of resistance offered to this agitation by the Polish authorities, who were interested in making the whole Ruthenian people suspect of irredentism. A grand campaign of agitation on the part of the Russian Count Bobrinsky, whose watch-word was that the Russian banner must wave over the Carpathians, though winked at by the Polish governor, led to a great political trial (Dec. 29 1913) for high treason of 180 Ruthenians who had been seduced by this agitator. It was not till towards the end of the war that the Austrian Government, in response to the wishes of the Ruthenians, began to come round to the idea of a separate status for Eastern Galicia; but it was then too late for such changes within the old territory of the empire.

The *Southern Slavs* were divided among four countries: Austria, Hungary, Serbia and Montenegro. Ban Jellačić, though loyal to the Emperor, had given expression to their aspirations towards unity as early as 1848; but Francis Joseph handed over the Croats and Serbs to Magyar domination (1867), and Dalmatia, the territory of the Austrian Croats, had been neglected by Vienna for years past; thus it was not till the years immediately preceding the war that it was rapidly developed by the construction of ports and railways and the encouragement of tourist traffic. The Slovenes, who inhabited Carinthia and Carniola, had less grounds for discontent, for the barren Karst had been afforested at the expense of the state; but though they were at the very gate of Serbia, they suffered from a shortage of meat, for Hungary obstructed the traffic in livestock in the interests of her great territorial magnates, and Austria bore the brunt of this. Vienna had for long been the hope of the Southern Slavs, and many of them had dreamed of a union under the Crown of Austria ("trinlism"). It was not till this failed them that they turned towards Belgrade.

Of the three *Latin races*, Italian, Ladin and Rumanian, national fragments were to be found in Austria. The Italians and Ladins, treated as separate in Switzerland, were in the Austrian official statistics treated as a single national group (like the Czecho-Slovaks and Serbo-Croats), but even then only totalled together 2·75% of the population of the empire. The claim set up by the Italians to a university of their own within the territory inhabited by them led to various controversies with the Germans and Southern Slavs. The Ladins, who formed about a quarter of this group, were not affected by irredentism, but looked rather towards German culture, and were to the end outspoken in their Austrianism. The Italian bourgeoisie of the towns, thanks to the force of attraction exercised by Italy, was all the more conspicuously irredentist, since the country population maintained an attitude of comparative opposition to this movement. Among the Rumanians, who inhabited three states (Austria, Hungary and Rumania), the desire long prevailed for union within the monarchy, and Austria would only have had to stretch out her hand to them; but the Magyars would not have it. Bukovina, the chief abode of the Austrian Rumanians, which they shared with the Ruthenians, offered the spectacle of a German administration in which without any compulsion German was the official language and also that of society, and neither efforts at Germanization nor language controversies were to be found. The Rumanians for years had proved themselves loyal to the State.

Constitution.—The establishment in Austria of universal suffrage in 1907 had as its aim the creation, in the place of the old Parliament, which was crippled by the strife of nationalities, of a Chamber in which social and economic interests should prevail over national ones. It had been believed that it was property owners and intellectuals who placed the question of nationality above all others, while behind them stood a solid mass of working-people who were uncorrupted by nationalist chauvinism. The Social Democrats in particular had always insisted that the working-classes were necessarily international. The House now consisted of 516 members, of whom 221 were of Slav nationality, 177 of German nationality, and 87 Social Democrats, so that in every national controversy the latter could carry a decision in accordance with their principles. In spite of this, the calculation was defeated; for in Europe every true democracy at once becomes national, and hence the national problem infected the working-classes so soon as they won parliamentary power; the "International" split up into national groups, just as the bourgeoisie had done before it. Thus the motive force of nationality proved itself stronger than that of Socialism.

With the introduction of universal equal suffrage the stormy suffrage agitation came to rest, although one of its demands was unfulfilled, namely female suffrage for the Austrian House of Deputies. Active committees for women's rights were, it is true, set up in the territorial capitals. The election of a woman as a deputy to the Diet, which took place prematurely through their influence in Bohemia in 1912, was annulled by the governor as illegal. Women's activity was, for the rest, kept free from demonstrations and excesses. They were not, however, without quiet success, for these committees worked so intensively to create a public opinion favourable to woman's suffrage that immediately after the proclamation of the Austrian Republic in 1918 the vote was unanimously conceded to women, even the conservative parties agreeing to this.

It might have been expected that the concession of universal suffrage in the case of the House of Deputies would have led to the abolition of the class system of voting for the legislative bodies of the several territories and the introduction of an equal franchise, and also to the doing away with the three-class system of voting—established on the Prussian model—in the case of the election of municipal representatives. This was all the more probable owing to the fact that since the Constitution of 1867 there had been a certain analogy between the franchise for the Reichsrat, the Territorial Diets, and the elected commercial bodies. The Social Democratic party endeavoured, indeed, to remove the last remains of the old electoral privilege in town and country; but the urgent motion which they brought in to this effect as early as July 8 1908 broke down, owing to a not unfounded anxiety lest in the Crown territories of mixed populations one nationality should predominate too much over another. There was only a cautious and gradual extension of the right to vote in Diet and municipal elections in the several territories; and it was not till Jan. 20 1918 that the Government adopted the point of view of the Social Democrats, and promised to extend the principle of the parliamentary franchise, as established in the case of elections to the Reichsrat, to the communal elections also, but with reservations intended to guard against "the undesirable reaction of nationality in districts of mixed population." The principle of full equality of electoral rights in all three spheres was not carried out till the republic.

Parliament.—The activity of the Austrian Parliament can best be characterized as a continuous inactivity. The two great recurring "necessities of State," the budget and the authorization of the contingents of army recruits, regularly occupied a large part of the sittings; the budget was generally passed only in instalments in three or six monthly grants, and the Government was forced to adopt the practice of adjourning the obstructive House of Deputies and of providing for indispensable requirements in its absence by emergency decree.

The procedure of emergency decree was based upon Par. 14 of the constitution, which provided that: "When pressing necessity for such measures presents itself at a time when the Reichsrat is not sitting, they may be promulgated by imperial decree, in so far as they do not produce any lasting burden on the State treasury." The current administration could, it is true, be provided for by this means, but new commitments could not be entered upon. This resulted, indeed, in a fairly economical administration, but nothing could be done on an imposing scale. Par. 14 of the constitution also contained a safety valve which enabled the Government to carry on current business for a time without the coöperation of the Parliament. The Government repeatedly exposed itself to the charge of proroguing

Parliament in order to avail itself of these emergency paragraphs. This procedure has often been blamed as unconstitutional; but the excuse must be taken into account that a constitution which provides such an emergency exit must be prepared for use to be made of it. The situation was often such that Parliament would not work, and the Government was faced with the alternative of stopping the machine of State or availing itself of emergency decrees. Such occasions arose even before the war on an average every two years.

The Reichsrat's right of control was secured after the event by the fact that the Government was bound, the next time it assembled, to lay the emergency decrees before it within four weeks; and that it could refuse its ratification. But before the war the Reichsrat never exercised this right, and thus each time the Government's proceedings were whitewashed. It was only in 1917 that the emergency decrees promulgated by the Stürgkh Ministry at the beginning of the war failed to receive ratification, in retaliation for the suppression of trial by jury by a military trial and the extension over civilians of the jurisdiction of the military courts. The normal processes of criminal jurisdiction were consequently restored. On July 26 1914 Stürgkh closed Parliament altogether, and non-parliamentary absolutism reigned for three years. At last Stürgkh's second successor again summoned the Reichsrat; but since its six years' mandate was expiring, it was prolonged by a special law towards the end of 1918. On the break-up of the State in 1918 the German deputies of this rump Parliament assembled to form the constituent national assembly of German Austria, while in the Czechoslovak and Yugoslav states there were committees from which the German and Italian deputies were excluded, which proceeded to take measures towards forming states.

Organized obstruction of parliamentary business by a section of members has been, of course, not confined to Austria. But it was in Austria that this singular procedure was first brought to technical perfection; and it became an Austrian speciality. The reason for this was that every party had cause to fear parliamentary oppression at the hands of other nationalities, and this was why it was long impossible to reconcile the principal parties in the House to any effective remedy. It was not till the end of 1909 that this was achieved by a tightening of the standing orders.

The standing orders under which the business of the Reichsrat was conducted were, as the law originally stood (1867 and 1873), intended for a dignified assembly of which each member aimed at avoiding disturbances. With the extension of the suffrage and the growth of nationalist conflicts, the powers of the president were no longer sufficient, and he was unable to deal with the obstruction of even a small group. At last, on Dec. 17 1909, after an 86-hour sitting, entirely occupied with debates on emergency motions, an emergency motion as to new standing orders proposed by the Polish group was passed; on the following day the Upper House adopted these resolutions, and on Dec. 20 1909 the new law was promulgated. By its provisions communications from the Government and the other House, and reports of commissions, had to take precedence of other business; further, the president could postpone to the end of the sitting formal motions, interpellations, emergency motions, and other obstructive measures. In the long run, however, even this palliative ceased to work; and accordingly on June 5 1917 a new stiffening of the standing orders was voted, which sufficed in effect during the later period of the Parliament.

Language Question.—There was no law regulating the question of what language was to be used in parliamentary debates. Every deputy might speak in his mother tongue; but custom had brought it about that, in order to be understood by the whole House, the members of Parliament spoke German. It was not till the Taaffe Government that it became a frequent thing for individual Slav deputies to speak in their own language. These speeches were generally not recorded by the stenographer; the Slavs protected themselves against this by gradually getting it accepted that polyglot stenographers should be appointed, that their speeches should be translated, and that they should be added as appendices to the parliamentary reports in the correct national language; finally it was resolved (June 1917) that all speeches should be reported *verbatim* in the parliamentary reports, in the language in which they were delivered. The Upper House agreed, but expressed its misgivings as to such a polyglot report of proceedings.

Administrative Commission for Bohemia.—In June 1913 the Government considered itself justified by necessity of the State in adopting a measure which in many respects was held to be a breach of the constitution; it appointed a commission for Bohemia, the members of which were nominated by the State, to deal with the autonomous affairs of this country. Since the last election in the spring of 1908 the Bohemian Diet had been unworkable, eventually owing to obstruction on the part of the Germans, who saw themselves handed over hopelessly to the Czech majority, until a rearrangement of the voting groups (*curiae*) should afford them protection against Czech oppression. In 1913 the Germans sent in a petition that each nationality should pay the costs of its own educational and cultural institutions, as otherwise one nationality would have to bear the expenses of the other, and *vice versa*. When the Czechs refused this request the Germans responded with more obstinate obstruction. The representative assembly now ceased to work, and since no legal expedient could in consequence be found by which legislation and current business could be carried on, the Government stepped in and appointed a mixed commission of Germans and Czechs, which should, as it were, administer the affairs of this country like a trustee for a person incapable of volition. This commission was admitted to have exercised its functions with impartiality as a matter of fact; but as a matter of form it stood on a weak foundation. The Germans were thereby deprived of their weapon of obstruction, and the Czechs lost the power of misusing their majority to oppress the Germans. The Czechs declared this to be a breach of the constitution; but the courts recognized the national commission as a measure of necessity justified in law. And so it subsisted until the break-up of the monarchy.

Administration.—The organization of the administrative system in the Austrian Empire was complicated by the fact that between the State and the purely local communal administration there intruded yet a third element, grounded in history, the territories (*Lander*). The State administration comprised all affairs having relation to rights, duties and interests "which are common to all territories"; all other administrative tasks were left to the territories. Finally, the communes had self-government within their own sphere.

To this division of the work of administration corresponded a three-fold organization of the authorities: State, territorial and communal. The State authorities were divided on geographical lines into central, intermediate and local, and side by side with this there was a division of the offices for the transaction of business according to the various branches of the administration. The central authorities, which as early as the 18th century worked together in a common mother cell of the State chancery, became differentiated so soon as the growing tasks of administration called for specialization; in 1869 there were seven departments, and in the concluding decade of the Austrian Empire there were set up Ministries of Labour, Food, Public Health and Social Care. Under these ministries came the *Statthalter*, whose administrative area had ordinarily the proportions of a Crown territory (*Kronland*); but the immense variations in area of the Crown territories made a uniform and consistent intermediate administrative organization practically impossible. The lowest administrative unit was the political sub-district (*Bezirk*) under an official (*Bezirkshauptmann*), who united nearly all the administrative functions which were divided among the various ministries according to their attributions.

Side by side with the State administration certain Crown territory administrations also existed in the 17 Crown territories, carried on by selected honorary officials, having under them a staff of professional officials. Many branches of the territorial administration had great similarities with those of the State, so that their spheres of activity frequently overlapped and came into collision. This administrative "double track," as it was called, led, it is true, in many cases to lively emulation, but was on the whole highly extravagant. The evils of this complicated system are obvious, and easy to condemn. They can be explained, partly by the origin of the State—for the most part through a voluntary union of countries possessed by a strong sense of their own individuality—partly by the influence in Austria of the Germanic spirit, well understood by the Slavs, which has nothing of the Latin tendency to reduce all questions of administration to clear-cut formulae as part of a logically consistent system. Like the English administrative system, the Austrian presented a rich variety, a variety indeed so rich that it clamoured for drastic reform.

Bienerth's last act as premier in May 1911 was the appointment of a commission nominated by the Emperor, to draw up a scheme of administrative reform. So early as 1904 Körber had declared a complete change in the principles of administration to be essential if the machinery of State were to continue working. After seven years of inaction, however, this imperial rescript was pitched in a far lower key. The continuous progress of society, it said, had made increased demands on the administration, that is to say, it was assumed that reform was not demanded so much by the defects of the administration but by the progress of the times, not because the administration was bad, but because life was better. It was an attempt to reform the administration without first reforming the State on equivalent lines. A reform commission without a programme naturally first occupied itself with reforms about which there was no controversy. After a year had gone by it drew up "Proposals for the training of State officials." After another two years it had indeed brought to light carefully prepared material for study, which was of great scientific value; but its proposals, though politically of importance, did not provide any basis for reform on a large scale. And so when the World War broke out the commission dispersed without practical results, leaving behind it an imposing array of folio volumes of great scientific value. It was not till March 1918 that the Seidler Government decided upon a programme of national autonomy as a basis for administrative reform, which was, however, never carried into effect.

Education.—The organization of the Austrian elementary schools was based on the principle of compulsory school attendance, free education, and the imparting of public instruction in the child's own language. Side by side with these existed private schools. The proportion of children attending private schools to those attending the public elementary schools in 1912 was 144,000 to 4·5 millions, *i.e.* a thirtieth part. Hence the accusation of denationalizing children through the *Schulvereine* must be accepted with caution. The

expenses of education were distributed as follows: the communes built the schoolhouses, the political sub-districts (*Bezirke*) paid the teachers, the Crown territory gave a grant, and the State appointed the inspectors. Since the State supervised the schools without maintaining them, it was able to increase its demands without being hampered by financial considerations. It is remarkable that the difference between the State educational estimates in Austria and in Hungary was one of 9·3 millions in the former as opposed to 67·6 in the latter. The elementary schools in Hungary were a State concern and a means of Magyarization, whereas in Austria their direction was left by the State to the nationalities. Thus in the former the schools were a means of denationalization, in the latter a means of national education. Under Austria, since everywhere that 40 scholars of one nationality were to be found within a radius of 5 km. a school had to be set up in which their language was used, national schools were assured even to linguistic minorities. It is true that this mostly happened at the expense of the German industrial communities, since the Slav labourers as immigrants acquired schools in their own language. The number of elementary schools increased from 19,016 in 1900 to 24,713 in 1913; the number of scholars from 3,490,000 in 1900 to 4,630,000 in 1913.

Illiteracy.—In proportion to the raised standard of popular education, further aided by the number of popular educational establishments which were springing up, and the university extension movement formed on the English plan, the proportion of illiteracy rapidly decreased. In 1890 the percentage of illiterates in the total population had been 28·5; in 1900 it had fallen to 22·7, and in 1910 to 16·5. As regards the several nationalities: among the Czechoslovaks in 1910 the percentage was 2·4; a little higher among the Germans (3·1) in consequence of the difficulties of school attendance in the Alpine territories; among the Italians 10·0, and among the Slovenes 14·7. The percentages were much higher among the peoples situated on the E. (Poles 27·4, Magyars 36·4, Rumanians 60·4, Ruthenians 61·0, Serbo-Croatians 63·7). It is their influence which explains the high average for the whole state.

Universities.—The higher educational establishments, which in the middle of the 19th century had had a predominantly German character, underwent in Galicia a conversion into Polish national institutions, in Bohemia and Moravia a separation into German and Czech ones. Thus Germans, Czechs and Poles were provided for. But now the smaller nations also made their voices heard: the Ruthenians, Slovenes and Italians. The Ruthenians demanded at first, in view of the predominantly Ruthenian character of East Galicia, a national partition of the Polish university existing there. Since the Poles were at first unyielding, Ruthenian demonstrations and strikes of students arose, and the Ruthenians were no longer content with the reversion of a few separate professorial chairs, and with parallel courses of lectures. By a pact concluded on Jan. 28 1914 the Poles promised a Ruthenian university; but owing to the war the question lapsed. The Italians could hardly claim a university of their own on grounds of population (in 1910 they numbered 783,000), but they claimed it all the more on grounds of their ancient culture. All parties were agreed that an Italian faculty of laws should be created; the difficulty lay in the choice of the place. The Italians demanded Trieste; but the Government was afraid to let this Adriatic port become the centre of an *irredenta;* moreover the Southern Slavs of the city wished it kept free from an Italian educational establishment. Bienerth in 1910 brought about a compromise; namely, that it should be founded at once, the situation to be provisionally in Vienna, and to be transferred within four years to Italian national territory. The German National Union (*Nationalverband*) agreed to extend temporary hospitality to the Italian university in Vienna, but the Southern Slav *Hochschule* Club demanded a guarantee that a later transfer to the coast provinces should not be contemplated, together with the simultaneous foundation of Slovene professorial chairs in Prague and Cracow, and preliminary steps towards the foundation of a Southern Slav university in Laibach. But in spite of the constant renewal of negotiations for a compromise it was impossible to arrive at any agreement, until the outbreak of war left all the projects for a Ruthenian university at Lemberg, a Slovene one in Laibach, and a second Czech one in Moravia, unrealized.

History

During the period from the assembly of the first Parliament elected by universal equal suffrage (1907) to the break-up of the Dual Monarchy, Austria itself had nine Governments under the following premiers:—

Baron Beck	June 2 1906—Nov. 4 1908
Baron Bienerth	Nov. 1908—June 19 1911
Baron Gautsch	June 26 1911—Oct. 28 1911
Count Stürgkh	Nov. 3 1911—Oct. 21 1916
Ernst von Körber	Oct. 28 1916—Dec. 20 1916
Count Clam-Martinitz . . .	Dec. 20 1916—June 23 1917
Ritter von Seidler	June 23 1917—July 25 1918
Baron Hussarek	July 25 1918—Oct. 27 1918
Heinrich Lammasch	Oct. 27 1918—Oct. 31 1918

All these ministries may be characterized as Cabinets composed of Government officials. Not one of their heads was drawn from the Chamber of Deputies. The Government was no longer the expression of the majority of the House, but had to be a non-party Government standing outside the House. An objective and non-party application of the laws, and equal rights for all nationalities, were in consequence the ever-recurring heads of their programme. From time to time, naturally, these Governments required a majority for the budget. They tried to arrive at it by negotiations with the parties, and by admitting to the Cabinet representatives of every nationality willing to coöperate. By this means the Cabinets acquired at least a measure of control over Parliament. A representative of Polish interests was generally to be found in every ministry, and usually too a minister of Czech and of German nationality. The political characteristics of these ministers are hardly distinguishable one from another; they all took their stand on a middle course of loyalty to the state and party impartiality. Beck, however, was held to be a shade more Slavophil, Bienerth Germanophil, Gautsch dynastic, Stürgkh a Conservative Socialist; Körber and Seidler were mere officials, Clam-Martinitz an old aristocrat, Hussarek and Lammasch Clericals. They regarded it as their principal task to bring about a compromise between the nationalities, and this again depended on the outcome of the German-Czech negotiations which were always being started afresh. In this none of these Austrian ministers succeeded.

Beck[1] *Ministry.*—With the carrying through of suffrage reform the Beck Ministry, which started in June 1906, had exhausted its strength. On June 17 1907 a promising speech from the throne opened the first universal suffrage Parliament and promised "to leave to the peoples as a secure heritage the integrity of their national territories"; "to solve the language question . . . on a foundation of equality of rights"; "to organize education with an equal consideration for all races"; "to introduce insurance against old age and infirmity . . . social reforms with regard to female and night labour, and an extension of the participation of the State in the exploitation of the coal-mines." Beck's next success was in reaching an understanding as to the language to be employed in Parliament. He also succeeded (July 12 1908) in bringing about an imposing procession in honour of the Emperor as an opening to the festivities of his diamond jubilee (Dec. 1848–1908). But apart from this celebration the second period of the Beck Ministry was attended by unfortunate incidents. On April 12 1908 Count Potocki, the governor of Galicia, was shot by a Ruthenian student. Then there was the Wahrmund affair. The Clericals started an agitation because Wahrmund, the professor of canon law at the university of Innsbruck, subjected the dogma of the Immaculate Conception to critical examination. They demanded from the Liberal Minister of Education, Marchet, that disciplinary measures should be used against him. The Minister endeavoured on the one hand to safeguard the principle of freedom of instruction, and on the other hand to avoid anything resembling a *Kulturkampf*. A general strike at the universities was averted by a compromise, by which Wahrmund was transferred from the pious land of Tirol to Prague, which was more than he had desired. In July a Pan-Slavonic congress took place at Prague, accompanied by anti-German excesses which had a serious sequel in Laibach. The Germans thereupon paralyzed the Prague Diet by means of obstruction, upon which the Czech members of the Beck Cabinet left it, and the prime minister, seeing himself abandoned by both Germans and Czechs, resigned on Nov. 14 1908. Shortly before this Beck had introduced yet another bill dealing with industrial insurance, to supplement the already existing sickness and accident insurance. The bill only received the assent of Parliament just before the break-up of the monarchy.

[1] Baron Max Vladimir Beck (b. 1854) entered the service of the State in 1876, in 1900 became head of a section in the Ministry of Agriculture, in 1906–8 Prime Minister; in 1907 he got universal parliamentary suffrage accepted; he was responsible also for far-reaching measures of railway nationalization.

Bienerth Ministry.—Beck's successor Bienerth [1] attempted to rule by means of a Cabinet of mere officials, in which under-secretaries of State were appointed as temporary directors of their respective departments. Moreover the three chief nationalities, the Germans, Poles and Czechs, were each represented by a so-called national minister (*Landsmann-Minister*). Bienerth's policy was to confine himself in a purely objective spirit to the execution of the laws until such time as he had gradually gained the confidence of the nation. The Germans made their coöperation contingent on various conditions. They insisted that the Government should introduce proposals as to the official language of functionaries, for they feared a return of the procedure used by Badeni, which by means of a Government ordinance had altered the received usage and upset the national balance of power; that in Bohemia the purely German sub-districts (*Bezirke*) should be included in German districts (*Kreise*), and in like manner the purely Czech sub-districts in Czech districts, so that there would then be a relatively small number of territories of mixed nationality, which would have to be governed bilingually; that minorities should be protected by law; and that in appointing to posts in the offices of the autonomous Bohemian territorial Government, proportionate consideration should be given to the Germans, attention being paid to the fact that in Bohemia more than a third of the population were German, and that they paid more than half the taxes, but that the Czech national majority had appointed more than 90% of Czechs and not even 10% of Germans in the Government offices. In purely German territories moreover it was claimed that only German officials should be appointed, just as in purely Czech territories the appointment of Czech officials was already uncontroverted and looked upon as a matter of course. Finally the old wish was put forward for a separation of nationalities in the representative assembly at Prague, in order that neither of the two nationalities should oppress the other in the internal affairs of Bohemia.

These German demands, which were exactly analogous to those formerly put forward by the Czechs, so long as they were still in a minority, now roused violent opposition among the latter. They called attention to the fact that the Germans in earlier days were deaf to such requests; they saw in them a "dismemberment of the country," and asserted that in the central public departments of Vienna, too, the Czechs did not occupy a number of official positions in proportion to their population. Serious excesses were now indulged in towards the German population and the German students in Prague, where, on the very day of the imperial diamond jubilee, the Government had to proclaim a state of siege.

The Reichsrat, which reopened under such conditions in Nov. 1909, stood under the threat of a paralyzing Czech obstruction. This time the Poles came to the rescue of the Government in its hour of need, by getting a form of standing order approved which rendered obstruction somewhat more difficult, and in this, curiously enough, they were helped by the Czechs; for obstruction had brought even them into an *impasse*, since their financial requirements had not been met. Thus the law for strengthening of the standing orders was carried through by an *ad hoc* combination of Poles, Czechs and Christian Socialists. But the freedom of parliamentary activity did not last for long. On Feb. 13 Bienerth went part of the way to meet the German demands by introducing a bill dealing with the rearrangement of the administrative districts (*Kreise*) in Bohemia. According to the statistical returns there were 139 administrative sub-districts where only Czech was spoken and 95 speaking only German, as opposed to only five bilingual ones. These 239 sub-districts, according to the bill, were to be grouped in 20 districts, 10 Czech, six German and four bilingual, in which provision was to be made for minorities throughout the whole land through official translation bureaus. This bill was intended to be a solution of the language question, which should take into account the actual conditions of the population as well as practical needs. The excitement with which the Czechs opposed this measure was extraordinary. They brought about a scene in Parliament which ended in hand-to-hand fighting and assaults, whereupon the Government immediately closed the Parliament.

In other directions, too, Bienerth's period of government was filled with hostile nationalist proceedings. The Italian students desired to revive the question of an Italian university, which had come to a deadlock, and in Nov. 1908 set on foot a great demonstration at the university of Vienna, in which the usual fairly harmless fighting with sticks was replaced by revolver shooting. In spite of this, Bienerth, with the consent of the Germans, introduced a bill in Jan. 1909 which was to set up an Italian faculty of laws provisionally in Vienna.

At this time the Czechs were trying to gain a foothold in frontier lands which had hitherto been considered solely German. They alleged as a reason that two small country communes of Lower Austria, Ober- and Unter-Themmenau, had a mixed colony of Czechs and Croats; it was further advanced on their side that a considerable annual migration to Vienna took place, which became Germanized in the second generation, and so lost to their Czech nationality. Vienna, with over 100,000 Czechs, was actually the second largest Czech town. In reality a still clearer diminution of the Czech population of Vienna was noticeable; according to the census of 1900, out of 1,674,000 inhabitants there were 102,970 Czechs, *i.e.* 6·1%; in 1910, out of 2,030,000 inhabitants, 98,400 Czechs, *i.e.* 4·8 per cent. The Czech colonies in Vienna endeavoured, by means of the so-called "Komensky schools" (from the Czech form of the name of Komenius, the educationalist), to protect themselves against fusion with the indigenous population. The Viennese Germans saw in this a danger to the hitherto peaceful common life of the population of Vienna. On Sept. 3 1909 the Lower Austrian Diet, in opposition to these Czech encroachments, tried to establish German by law as the language of instruction in all the public schools of Lower Austria, in correspondence with the actual state of affairs hitherto. On Oct. 7 Burgomaster Lueger insisted that Vienna could only be a unilingual city, as otherwise she would have to speak nine languages; and on Jan. 18 1910 this resolution received the force of law. Analogous laws were promulgated in the three other purely German Crown lands.

After the Tauern railway had been built for the Alpine countries—without, it is true, any particular pecuniary help from the Polish part of the empire, which was known to be only passively interested—the Poles demanded a complete carrying into effect and extension of the waterways law, with a larger State subsidy. It was over these demands in connexion with the waterways, which the Minister of Finance declared to be impossible of fulfilment to the extent required by the Poles, that Bienerth's mainstay failed to support him; and on Dec. 12 he sent in his resignation, which was, however, followed by a renewed Bienerth Ministry, composed of Germans, Poles and officials. By means of this coalition the Ministry succeeded, indeed, in passing the military service reforms on April 24 1911 (reduction of the three years' service to two years, combined with an increase in the contingent of recruits); but this completely exhausted its parliamentary strength, and the first parliamentary suffrage Parliament ended with but poor results in the midst of unsolved national problems.

Since 1910 a meat shortage in Austria had made itself more and more felt, especially in the towns, owing to their rapid growth, the decrease of cattle-raising in the Alpine lands, and the reduction in the imports of Serbian meat through the anti-Serbian agrarian policy of Hungary. The Christian Socialist party, from being originally an urban party, had become partly an urban and partly a peasant party, and the Minister of Commerce, Weisskirchner,[2] who had come from its ranks, had not

[1] Baron Richard Bienerth-Schmerling (1853-1919) was made Minister of the Interior in June 1906; Prime Minister Nov. 1908–June 1911; and till 1915 he was Statthalter for Lower Austria.

[2] Richard Weisskirchner (b. 1861 in Vienna) entered the municipal service in 1883 and became in 1903 president of the town council; 1909-11 Minister of Commerce; 1912-8 Burgomaster of Vienna; a deputy from 1896 onwards; and in 1907 president of the Chamber of Deputies. He was a disciple of Lueger, a Christian Socialist, and framed a new municipal statute and associations based on the Christian view of society.

only to reckon with the opposition of Hungary but also to pay particular attention to the peasant voters, in the question of buying meat abroad and importing frozen meat from the Argentine. On this account, especially after the death of Lueger (on March 10 1910), a dominating personality who had held all parties together, opinion in Vienna and other towns turned against the Christian Socialists, who were accused of refusing all active measures of relief. Thus it happened that the elections to the Reichsrat in July 1911 were characterized by a temporary coalition of the German Liberals with the Social Democrats against the Christian Socialist party; this led to heavy losses on the part of the latter, especially in the towns. In Vienna especially they lost every seat at one blow, by which means Weisskirchner found himself deprived of all parliamentary support. He resigned, and with him the head of the Cabinet; all the ground had slipped from beneath his feet, and on June 19 1911 Bienerth resigned for good.

Gautsch Ministry.—The Bienerth Government was succeeded by that of Baron Gautsch.[1] He too could attempt nothing more than to take up as objective an attitude as possible above parties. His first task was to try to set in motion again the negotiations for a German-Czech compromise in Bohemia. The Czechs, however, had realized that at need they could get along without a Diet, and they began once more their encroachments in Vienna. They opened a Komensky school there without proper authorization, and when this was closed by the municipal authorities, they organized a demonstration of Czech women, who crowded with their children into the Parliament House. Shortly before this the protests of Hungary had succeeded in procuring the rejection of a cargo of Argentine frozen meat which had been destined for Vienna. The fury of the Viennese found expression in violent demonstrations, in which, for the first time, employees of the State took part in uniform, among them employees of the State railways and of the post-office. Gautsch, who was a convinced upholder of the principle of State authority, had recourse to severe measures of punishment and discipline, which had as their result a revolver attack on the Minister of Justice from the gallery of Parliament.

On Oct. 28 somewhat unexpectedly the prime minister resigned, partly because this series of unfortunate incidents had shaken the Emperor's confidence, partly because his secret efforts to persuade the Czechs to join his Cabinet had made him suspect to the other parties. But the Czechs not only demanded two Czech ministers, but also a number of headships of departments and councillorships in each department. This would have led to an introduction of the national divisions into the central administration, and if similar claims were put in by other nations the principle of a purely objective Government transcending nationality would have been done away with. So Gautsch would have nothing to do with it.

Stürgkh Ministry.—Count Stürgkh (b. 1859), the Minister of Education, was next entrusted with the formation of a Cabinet. He composed his Cabinet of colourless officials and confessed adherents of the various nationalities. His programme was to be an honourable mediator in the German-Bohemian quarrel, to extend the railway system, and to satisfy the wishes of the Poles in the waterways question by an expenditure of 73·4 million *kronen* on canal construction in Galicia, to which Galicia was to contribute only 9·4 million *kronen*, the State finding the other 64, and by an expenditure of 125 millions on river improvements, 99 of which would be contributed by the State.

Early in Stürgkh's Ministry prominence was taken by the Catholic marriage question. While in Austria the marriage of non-Catholics could be dissolved, so as to make a new marriage possible, paragraph iii. of the civil code provided that "the tie of a valid marriage between Catholic persons can be dissolved only by the death of one of the parties. And this shall be the case even when only one party was attached to the Catholic religion at the time of the conclusion of the marriage." Thus Catholic and mixed Catholic marriages were indissoluble even in the event of a change of creed. The desire of numerous divorced persons for a change in the law which prevented their remarriage was manifested in repeated demonstrations before Parliament; especially in that of Dec. 1911, in which it was asserted that the lives of half a million divorced wives were affected. In spite of the reform of the civil law in other respects (June 1 1911) these provisions remained in force until the republic. Owing to the opposition of the Christian Socialist party, they were even then not abolished; but they were relaxed by numerous dispensations in individual cases.

[1] Baron Paul Gautsch von Frankenthurn (b. 1851) had been Premier and Minister of the Interior, 1897-8, and Premier 1904-6.

It was while Stürgkh was Austrian premier that the World War broke out (*see* under FOREIGN POLICY, p. 327). At the beginning of the war the attitude of the nationalities of the Austrian Empire was somewhat unexpectedly loyal to the state. The immediate cause of war—the murder of the heir to the throne—had profoundly impressed all the Austrian peoples, and the belief that efforts were being made from without to destroy the old empire produced among them a strong reaction in favour of its preservation. Enrolment in the army proceeded everywhere without friction, and much more expeditiously than the military authorities had expected. It was only to be expected that the Germans, whose very existence was in question, should show themselves to be patriotic. But it was somewhat surprising that at Prague, after the declaration of war, Germans and Czechs sang *Die Wacht am Rhein* together in the streets, and the burgomaster, a Czech, made a speech in German before the town hall in which he called for cheers for the Emperor William and the fraternization of Germans and Czechs. On Oct. 24 1914 the Czech Union solemnly declared: "It is true that we have been against one Government or another, but never against the state." On Nov. 15 the Czech parties in Moravia issued a patriotic manifesto. The procedure of the Poles was similar; all the Polish parties united in a joint central committee which issued a manifesto in favour of performing their duty to the state (Aug. 15). On Aug. 27 the Ruthenian Metropolitans, too, issued a protest against "tsarism," and in like manner the Ukrainians protested (Nov. 1) against Russian oppression of freedom of conscience. On Nov. 23 30,000 Rumanian peasants of the Bukovina got up a great manifesto in favour of the emperor and the empire, and on Dec. 1 patriotic protestations from the Rumanian Club followed. These proclamations on the part of all the Slav peoples of Austria proved that imperial sentiment was more deeply rooted than Austria's enemies had believed.

These evidences of patriotism continued for a long time during the war; even after Italy's declaration of war the majority of the Italian deputies in S. Tirol issued a loyal declaration "in the name of the overwhelming majority of the population," as they asserted (June 14 1915). On the other hand the efforts made for years by Panslav idealists, Russophil agitators, Serbian propagandists and Italian irredentists, were naturally not without effect. Isolated instances of relations being established with co-nationals in the enemy camp were recorded from the beginning. The question was repeatedly raised as to why the prime minister did not take advantage of this patriotic spirit to obtain a corresponding parliamentary demonstration; but it had surprised him, as it had many, and he shrank from the serious responsibility which would have resulted if the experiment had turned out badly; the aged Emperor's need of quiet, and the conviction that the Reichsrat, if summoned *ad hoc*, would, as for so long before, be of no active use, also played their part. The population had not been consulted as to the declaration of war, and their opinion was no more listened to now; but by giving up the coöperation of Parliament the prime minister at the same time abdicated his power in favour of the military authorities. Since there was no longer a Parliament, or any personal immunity, the military authorities established unlimited police rule, which seemed to be obsessed with terror of its own citizens; anyone who seemed to them suspect was subjected to internment in concentration camps. This ruthlessness towards their own citizens, who were arraigned before military courts in trials for high treason, stood in curious contrast to the considerate treatment of "enemy aliens," who were comparatively little molested. For example, even many

months after the beginning of the war advertisements were to be read in all the papers, in which English and French people offered to teach languages or instruct children even in English and French, stating their nationality and address—a proof that the authorities did not put any particular difficulties in the way of these foreigners, and that the people did not take advantage of knowing their addresses to molest them.

The political impotence of the prime minister was plainly evident in the military proceedings against Kramarz, in which Stürgkh shook hands with the accused and gave evidence in his favour, but without being able to avert the death sentence passed by the military court, though he did at least prevent the execution of the sentence.

During the later part of the Stürgkh Ministry it is no longer possible to speak of an internal policy, for the military alone ruled. Towards the end, however, Stürgkh was actually endeavouring to bring about a reassembly of the Reichsrat, when he was shot by the Independent Socialist Dr. Friedrich Adler (Oct. 21 1916).

Körber Ministry.—The object of the murder of Stürgkh, namely, to lead to a powerful demonstration in favour of the summoning of the Reichsrat, was not attained; at a meeting held between some deputies and members of the Upper House (Oct. 23 1916) no definite proposal to this effect was brought forward, and the Körber Ministry, which was summoned on Nov. 1, ruled during its eight weeks' period of activity without Parliament. On Nov. 14 Körber set up an office for food control (*Volksernährungsamt*) which later became the Ministry of Food (Jan. 1917). Little else was done; the approaching death of Francis Joseph (Nov. 21) prevented any far-reaching plans. When the worn-out old Emperor was succeeded by an immature boy, the serious, positive and somewhat "schoolmasterish" Körber did not strike the right note with him. Charles I. could not forgive Körber for prevailing upon him to promise to take the oath to the constitution, since the constitution was no longer tenable and Stürgkh had already prepared constitutional amendments; on the other hand Charles's assumption of the supreme command of the army was opposed to Körber's taste. When Körber declined to carry through the *Ausgleich* with Hungary without consulting Parliament, and made it a question of confidence the young Emperor on Dec. 20 1916 lightly dismissed his best adviser.

Clam-Martinitz Ministry.—Körber's successor, Clam-Martinitz,[1] who belonged to the violently Czech feudal nobility, tried to form a national coalition Cabinet, including two German politicians. The political event of the moment was President Wilson's note (Dec. 11 1916) and the Entente's answer (Jan. 12 1917) as to the liberation of the "oppressed" peoples of Austria. It called forth sharp counter manifestoes on the part of those who were to be "liberated." A resolution adopted unanimously on Jan. 17 1917 by the Croatian representatives proclaimed, as a condition of the national existence and the cultural and economic development of the Southern Slavs, that they should remain under the House of Habsburg. The Czech Union rejected, by a unanimous resolution of its governing committee, the suggestions of the Entente, as being insinuations based on erroneous premises, and deprecated by a reference to their secular allegiance "the interference of the Entente Powers" (Jan. 23 1917). Koroschek, the Slovene leader, wrote to the minister in the name of his party that "these hypocritical assurances have called forth nothing but indignation among the Southern Slavs" (Jan. 1 1917). The Rumanian Club made a similar declaration on Jan. 24.

The hope of achieving parliamentary coöperation on the basis of such loyal declarations as these soon vanished. The Germans demanded, as a condition precedent to the effective participation of their nationality in the affairs of the state, an alteration of the constitution by imperial ordinance (*Oktroi*), which should define the boundaries between the nationalities in Bohemia, rearrange the districts (*Kreise*) accordingly, declare German to be the language in which the business of the Reichsrat was to be conducted, and lay down more stringent rules of procedure. The Slavs, on the other hand, demanded the "unconditional" summoning of Parliament. The Germans yielded, and the Reichsrat met on May 31. Both the Southern Slavs and Czechs immediately made constitutional declarations; the former demanded a national union of the Southern Slavs, the latter a territorial union of the lands S. of the Sudetic Mountains, while the Germans opposed any transformation of the monarchy into a federal state. In the face of this uncompromising display of opposition there could be no hope for the Coalition planned by Clam-Martinitz for the creation of a new Austria, and on June 19 he resigned.

Seidler Ministry.—On June 24 1917 the Emperor appointed as prime minister his former tutor, the Ritter von Seidler,[2] who summoned a Ministry of mere officials, just to carry on business for the time being; any constitutional reorganization was still postponed. On July 2, on the occasion of the Crown Prince's birthday, the Emperor proclaimed a wide measure of amnesty, in which on July 10 even Kramarz and his confederates were included. This precipitate action aroused the mistrust of the Germans, and, in view of the ambiguous attitude of the prime minister towards the Czechs, led to a vote of censure being passed at a meeting of the German national council at Prague on July 15.

Seidler now resolved to undertake the reconstruction of the crumbling body politic, with a reorganized Cabinet (Aug. 31 1917). A great economic and social programme was announced, including the extension of waterways, the exploitation of electricity, an improved system of communication, industrial insurance, and a department for public health. Politically the organization of the state on the fundamental principle of national autonomy was to follow; he hoped to get round the nationalist obstacles in Bohemia by a rearrangement of districts with local delimitation according to nationality. This bold plan met with no success; the economic programme in particular did not come into force; it was an empty promise, which was not taken seriously. But the political programme, on the other hand, let loose a violent attack of the Slav nationalities on the state. The Polish committee, which had been formed on a political basis, was dissolved after unprecedentedly stormy negotiations, due to discontent at the cession of Chelm (Kholm) to the Ukraine; the Poles threatened the rest of Austria with a boycott of food, and abstained from voting on the budget. The action of the Czechs was even more dangerous to the state; on Jan. 12 1918 a meeting of their deputies at Prague unanimously accepted a resolution to the effect that the Bohemian question was to receive an international solution at the Peace Congress. Seidler regretfully pointed out in Parliament on Jan. 22 that this resolution was totally opposed to that of May 1917, which could still be reconciled with the fundamental conceptions of patriotism. The Germans rejoined with a demand for a province of their own, German Bohemia, separate from Czech-Bohemia (Jan. 22). Similarly the Ruthenians demanded that East Galicia should be erected into a separate Crown land under the name of the Ukraine (March 3). Since the Northern and Southern Slavs had absented themselves and the Poles were in opposition, the Reichsrat was adjourned (May 3), and the Germans now again demanded the grant of a revised constitution, with German as the language of State, a special status for Galicia and Dalmatia, access for the Germans to the Adriatic, and the partition of Bohemia. Seidler granted indeed a rearrangement of districts in Bohemia (seven Czech, four German and two mixed); but he could not make up his mind to go further, and tried the expedient of summoning a fresh Parliament on June 16. But the day before

[1] Count Clam-Martinitz (b. 1863), an hereditary member of the House of Lords, and chairman of the Committee of Privileges in it, had been head of the Ministry of Agriculture from Oct. 31 1916; up to June 23 1917 he was Prime Minister, then Governor of Montenegro till 1918.

[2] Ritter Ernst von Seidler (b. 1862 at Schwechat, near Vienna) was secretary to the Chamber of Commerce in the mountain town of Leoben; then an official in the Ministry of Agriculture, and from June 1 1917 Minister of Agriculture; he was also a university reader in constitutional law.

the Czechs had set up a national committee, with Kramarz at its head, which adopted the programme of "a Czechoslovak State sovereign and independent." They proposed the impeachment of the minister responsible for the nomination of the chiefs of the districts, and declared that they would take no part in revising the constitution. His plans having thus been completely shipwrecked, Seidler resigned on July 22 1918.

Hussarek Ministry.—Hussarek,[1] who was appointed prime minister on July 24, declared his programme to be parliamentary government, with reconciliations of the nationalities, and constitutional and administrative reform. The Czechs, however, declared that, so far as they were concerned, nothing had been altered. Hussarek got through a six months' provisional budget with the help of the Poles against the votes of the Ukrainians, a proof that he had shelved the partition of Galicia. Immediately afterwards the Reichsrat adjourned for the summer holidays (July 26), without having ventured on any steps towards the solution of the great problems of State.

The process of dissolution advanced rapidly, when England on Aug. 17 recognized the Czechoslovaks as an allied nation; to which the Austrian Government replied with the declaration that no such state existed, but only individual traitors. In a communication to the press on Sept. 4 Hussarek insisted that there were no oppressed peoples in Austria, that on the contrary her constitution assured to the several nationalities a status of equal rights like that of no other state on earth, and he gave a warning against its destruction—a vain appeal to reason. On Sept. 18 the Czech National Council had already imposed some taxes. On Oct. 1 Hussarek again gave the Reichsrat a chance; he recognized expressly the right of the peoples to free self-determination, adopted the standpoint of national autonomy, championed Polish independence, and announced the union of all the Southern Slavs of Austria by constitutional means. This programme met with a cool reception; the Poles by now were expecting a new organization from the Peace Congress; the Southern Slavs desired union with those of their race in Hungary also; the Czechs opposed the division of the administrative commission into two parts; they did not want autonomy for their nation, but incorporation of the German Bohemians in their State, and refused all negotiations.

The Emperor now made a last despairing attempt; a manifesto of Oct. 16 proposed the conversion of Austria—not of Hungary, it is true—into a federal state composed of free nations, each with the territory which it occupied. This was far from resulting in any coöperation of the nationalities in realizing their former ideal; on the contrary, they felt themselves free from all constraint, and formed Governments having no connexion with the old state. On Oct. 19 the Ukraine National Council was set up in Lemberg, and the Slovene-Croat in Agram; on Oct. 20 the Czechs followed suit in Prague, on the 21st the German delegates in Vienna, on the 25th the Magyars in Pest.

Lammasch Ministry.—The summoning of the last Ministry of the Austrian Empire, under Lammasch from Oct. 27-31 1918, could only be regarded as an attempt on the part of the impotent Monarch to bring about a friendly liquidation between the peoples who were separating from each other. But since the non-German nationalities were not prepared to accept such a peaceful settlement, the liquidation between the monarchy and the new republic was confined to German-Austria, and Lammasch's friendly offices might certainly be thanked for the fact that in this quarter the settlement was achieved quite bloodlessly, in favourable contrast with the two years of fighting between Czechs, Poles, Ruthenians, Magyars, Rumanians, Southern Slavs and Italians. Lammasch and his ministers shared their official premises peacefully with the new secretaries of state of the Austrian Republic, and his last official act was to send out posters with an appeal for peace and quiet. (For the later history, *see* AUSTRIA, REPUBLIC OF.)

[1] Baron Max Hussarek (b. 1860) professor of canon law at the university of Vienna, was of clerical leanings; he was Minister of Education from Nov. 3 1911 to his appointment as head of the Cabinet (July–Oct. 1918).

BIBLIOGRAPHY.—The *Oesterreichische Politische Chronik*, published by Neissel (Vienna 1910-8), contains among other things an account of the most important transactions of all the public bodies (Parliament, the Delegations, etc.); *Neuere Gesetzgebung Oesterreichs nach den Reichstagsverhandlungen* (Vienna); H. ECONOMIC CONDITIONS

Pre-War Period.—During the years 1910-4, immediately preceding the World War, economic conditions in Austria showed no uniform tendency, for in many fields the signs pointed to a crisis, while in others developments seemed full of promise. These conditions were undoubtedly determined by the critical political situation from 1908 onward, which made it probable that, sooner or later, the Habsburg Monarchy would have to fight for its right to exist. It is true that nobody could have foreseen coming events; but things kept on occurring which counselled prudence, and threatened the economic situation from without. Added to this the state saw itself compelled, in view of the political situation, to increase its expenditure on armaments; and since this expenditure grew at a rate with which the revenue could not keep pace, the Government had constantly to raise large sums by borrowing in the open market, and in 1912 had even to raise a big loan in America. All this, combined with the stringency of the international money-market, meant a heavy burden on Austrian national economy. Voices were not lacking which, in view of Austria's relatively small share in foreign investments, ascribed the deterioration of the trade balance to the fact that the public bodies were "living beyond their means." (From 1875 onwards the balance of trade had been in favour of Austria; in 1907 it turned against her, and from this time the adverse balance showed a steady increase until 1913, when it slightly diminished.)

According to the census of 1910, out of 16 million persons following an occupation 8·5 millions were engaged in agriculture and forestry, 3·6 in industry, 1·6 in commerce and transport, 2·3 in the public services, liberal professions, etc. Agriculture is thus the basis of economic existence for the greater part of the population; and the favourable crop statistics for the last years preceding the war, and especially the record harvest of the year 1912, must have had a beneficial influence upon the economic situation. The production of the most important crops for the whole of Austria is shown in Table I.

TABLE I.—Crop Statistics.

(Thousands of tons.)

	1910.	1911.	1912.	1913.
Wheat	1,539	1,574	1,861	1,594

Barley	1,446	1,591	1,676	1,719
Leguminous crops	258	237	245	232

We must consider, in this connexion, that the prosperity of certain industries depends directly upon the results of the harvest. It was only in years when the harvest was most favourable that Austria-Hungary was able to provide for her own requirements in corn; for export purposes only barley was of considerable importance, while wheat, and above all, of recent years, maize had to be imported. In Table II. is shown the excess of imports of grain over exports (+), or of exports over imports (−).

TABLE II.
(Thousands of tons.)

	1909.	1910.	1911.	1912.	1913.
Wheat	+0·720	+0·278	+0·130	+0·008	+0·017
Barley	−0·185	−0·170	−0·648	−0·196	−0·166
Maize	+0·100	+0·036	+0·193	+0·726	+0·643
Other varieties of grain	+0·127	+0·076	+0·216	+0·083	+0·061

In Table III. are given the average prices of the most important varieties of grain.

TABLE III.—Average Prices, Vienna (in *kronen*).

	1909.	1910.	1911.	1912.	1913.
Wheat	15·50	12·94	12·96	12·69	12·31
Rye	10·47	8·55	9·86	10·80	9·47
Barley	9·83	9·02	10·32	10·67	9·19

The prices of the principal kinds of meat do not show the same tendency as those of corn; it is only after 1911 that a certain pause can be remarked in the rise of prices, as Table IV. shows:—

TABLE IV.—Retail Price of Meat, Vienna (in *kronen*).

	1909.	1910.	1911.	1912.	1913.
Beef	171·53	177·90	195·68	207·12	217·46
Pork	172.00	195.00	200.00	200.00	200.00
Veal	145.00	153.00	160.00	160.00	180.00

The statistics of sugar are given in Table V.:—

TABLE V.—Sugar.
(Thousands of tons.)

	1909–10.	1910–1	1911–2.	1912–3.
Raw sugar produced	1,246	1,523	1,143	1,899
Internal consumption	592	669	577	672
Number of workmen employed	72,205	73,908	70,907	72,960

The price of sugar in Vienna showed in 1913 a considerable fall, following the good harvest. The total production for the year 1912-3, and also the amount of consumption, are the highest recorded in Austria.

As to the products of other industries closely related to agriculture that of beer and brandy varied, and was at times extraordinarily large.

The old Austria was very richly provided with raw materials; the coal and iron supply was especially rich; in the years immediately preceding the war the production of these two commodities followed in general a rising curve. Table VI. gives the quantities of important mineral products.

TABLE VI.—Mineral Production.
(Thousands of tons.)

	1909.	1910.	1911.	1912.	1913.
Coal	13,466	13,526	14,121	15,513	16,164
Brown coal	25,575	24,680	24,810	25,810	36,705
Iron-stone	2,475	2,580	2,716	2,874	2,985

The amount of manufactured iron produced was also on the increase; the quantities in thousands of tons were:—

	1909.	1910.	1911.	1912.	1913.
Refined iron	1,193	1,218	1,305	1,447	1,458
Cast iron	246	256	261	281	268

After 1908 the Austrian textile industry suffered from a serious depression; owing to the extraordinarily steep advance in the prices of raw materials the position of this industry was unfavourable, in spite of increased production and rising prices at the spinning mills. The figures for the cotton industry are representative:—

Imports of Cotton.
(Thousands of tons.)

1908.	1909.	1910.	1911.	1912.	1913.
187	200	183	210	234	222

The number of cotton spindles in Austria was: in 1910, 4,643,300; in 1911, 4,563,700; in 1912, 4,797,900; in 1913, 4,909,458. After 1910 an ever-increasing quantity of cotton had to be exported.

Exports of Cotton.
(Thousands of tons.)

1908.	1909.	1910.	1911.	1912.	1913.
4·2	4·0	5·1	7·0	10·5	24·2

The number of looms increased steadily, hut the output per loom showed partially a distinct decrease.

A good general impression of the economic situation can easily be gained from the raturns of the state of the labour market. Table VII. shows how many offers of places corresponded on a yearly average to every hundred applications for work:—

TABLE VII.—Employment per 100 Applications.

	1911.	1912.	1913.
Smelting	45·5	52·5	73·8
Metal-working	64·0	68·3	45·3
Machine industry	42·5	51·6	36·8
Wood industry	87·2	85·7	48·3
Clothing manufacture	95·0	94·9	74·6
Textile industry	146·1	91·2	48·2
Paper industry	83·6	90·1	53·4
Building trade	80·6	85·2	61·8
Clerical occupations	61·6	58·7	47·9

An improvement was shown only in the position of employees in smelting works, otherwise a deterioration is to be observed everywhere, most markedly in the textile industry. In spite of this wages showed a rising tendency. Table VIII. gives the average daily wage (based on the returns for the accident insurance contribution):—

TABLE VIII.—Average Daily Wage in Vienna (in *kronen*).

	1910.	1911.	1912.	1913.
Smelting	4·10	4·22	4·27	4·41
Metal-working	3·45	3·52	3·61	3·77
Machine industry	4·17	4·21	4·40	4·65
Textile industry	2·36	2·45	2·47	2·58
Wood industry	2·79	2·94	3·00	3·13

The cost of living increased on the whole; it wus only in 1913 that there was a fall in the price of certain important commodities. The average prices per kilogram of certain commodities in Lower Austria are shown in Table IX.:—

TABLE IX.—Average Food Prices (heller per kilogram).

	1909.	1910.	1911.	1912.	1913.
Meat (*Suppen fleisch*)	159·8	162·9	180·0	194·8	198·5
White flour	46·3	39·7	39·1	38·9	38·0
Peas	48·7	51·2	52·3	56·1	55·7
Potatoes	10·4	11·6	14·2	14·4	12·5
Sauerkraut	37·1	29·6	30·7	33·3	29·1
Rice	56·5	55·5	56·9	60·1	56·3
Lard	175·5	186·7	194·4	197·6	203·4

This very cheapening of many commodities in 1913, side by side with which went also a cheapening of many manufactured articles, was indicated as the sign of a decline in the power of consumption of the population.

It may here be mentioned that according to the savings bank returns there was also a decline in the amount of deposits. The deposits and withdrawals were respectively, in thousands of kronen:—

	1910.	1911.	1912.	1913.
Deposits	1,706	1,860	1,950	1,872
Withdrawals	1,610	1,790	2,149	1,970

After the heavy withdrawals of 1912 the decline in deposits, together with a continuance of heavy withdrawals in 1913, is a clear sign of economic depression. The economic situation of Austria shared in this respect in the general development of world affairs, in which also, after a period of prosperity, a reaction set in in 1913. It is only surprising that in 1912 the reaction already showed itself sharply in Austria. The year 1914 soon showed signs of a coming relaxation of the economic crisis; but this development was interrupted by the World War.

The War Period, 1914–8.—The outbreak of war meant the almost complete paralysis of industry in Austria. Only the very narrow range of goods manufactured in peace-time found buyers, and these were used exclusively for the equipment of those going to the front. The bulk of industry found itself faced with the impossibility of disposing of the goods previously manufactured, and acted in consequence as best suited the interests of the moment: there were general dismissals of workmen, and enterprises were restricted or suspended. Numerous industries were almost entirely dependent upon export trade (*e.g.* the glass and porcelain industry in Bohemia), but foreign relations were to a large extent broken off through the closing of trade-routes and the entry into the enemy camp of countries which had been important markets. Thus during the first weeks of the war there was very great unemployment in parts of the industrial regions, since the dismissals far exceeded the proportion of enrolments in the army, while agriculture, which was already occupied with the harvest, suffered from a serious shortage of labour.

The Government had not prepared in advance any measures

for setting industrial production going again in any way. Its first steps in war economy were confined to the sphere of finance and credit: the *bourse* was closed, and a moratorium announced. With regard to the latter, however, the requirements of industry were studied to a certain extent, in that the withdrawal of money from the banks was allowed, so far as it was necessary for paying wages and for the provision of working capital.

There was no revival of industry until the orders of the military authorities began to come in, which gave lucrative employment. In a short time, and without any pressure from the Government, but solely as a result of the favourable prices it offered, industrial conditions were completely transformed so as to meet the exigencies of the war. At first indeed, since the war was only expected to last a short time, there was little disposition to incur the heavy expenditure necessary in order to secure a share in the manufacture of war material; but this attitude was soon changed, and within six months factories everywhere had been adapted to the supply of munitions and all the variety of other things required by the Government for the armies. Industry was thus in many ways compensated for the paralysis of trade with private buyers in the home market and for the closing of foreign markets, and it would have been able to continue quietly on the old lines but for the emergence of a new factor which fundamentally altered the conditions. This factor was the rupture of communications with foreign countries, due in the earlier stages of the war to the limitation, and at one time the prohibition, of exports by neutral countries, the passing over of some of these countries to the enemy, and lastly the blockade by the enemy Powers, which increased in efficiency and made it more and more difficult to import the most essential commodities, until in the end it was almost impossible to obtain from abroad anything, needed either for the soldiers or the civilians.

In this respect Austria found herself in the same position as the German Empire; in fact, her position was in many respects considerably worse; many richly productive territories were temporarily occupied by the enemy; and as Austria was far less well provided with raw materials than Germany she was less in a position to produce goods for exchange. In addition to this there was another quite exceptional source of difficulties which had the most serious consequences for Austria, namely her relation with Hungary, due to the peculiar constitutional structure of the Austro-Hungarian Monarchy. The Hungarian Government could claim the right to take independent economic measures for her own territory in war-time; a joint arrangement was only possible for the territories of the Dual Monarchy—which were united for tariff purposes—by agreements between the Austrian and Hungarian Governments; and since neither Government was exclusively concerned to carry out an adjustment of economic conditions solely in accordance with what was necessary for waging war and holding out with the supplies at their disposal, but each had also to champion the interests of one half of the monarchy against the other, the negotiations between the two Governments were often attended with the greatest difficulties, and constantly ended unsatisfactorily. Hungary, in accordance with her economic situation, had always the advantage in these negotiations, since she was incomparably richer than Austria in foodstuffs, and the latter was constantly thrown back upon Hungarian supplies; and this superiority on the part of Hungary became more and more definitely pronounced in proportion as the provision of the necessities of life for the army and civil population became a steadily-increasing anxiety.

The more complete the economic isolation of the monarchy the more the lack of raw materials made itself felt, both for the manufacture of indispensable war supplies and for the feeding of the civil population. To prevent the war being brought to a premature end by dearth of supplies, the Government took measures, modelled on those adopted in Germany, for ensuring that necessary goods should be supplied to the proper quarters—whether the army authorities, manufacturers of war material, or consumers—and at a moderate price.

The quantity of raw materials which Austria had been in the habit of importing from abroad, and the quantity stored in the country at the outbreak of the war, were comparatively very small. The Austrian and Hungarian ports were of little importance as ports of entry for raw materials, the goods stored there being mainly from the Levant. On the other hand, wool, cotton, metals, etc., which came from overseas, were imported through German or Dutch ports, and were stored there, though often already in Austrian ownership. It was of the first necessity to assure the transport through Germany of these Austrian-owned goods, and an agreement with the German Government securing this was made. Agreements were also concluded by which a share of the goods owned by Germany was conceded to Austria.

It was next necessary to organize the purchase of goods in neutral countries. This was at first left wholly to private enterprise; but, as Austrian buyers not only competed with each other but also with buyers from other countries, this was bound to send up prices, while the interests of the State were subordinated to private gain. To meet this situation Germany set up central boards (*Zentralen*), and Austria followed suit, partly at the request of the German Government, which wished to avoid the competition of Austrian agents. Since the functions of these organizations were commercial, for which the regular Government officials were unsuited, they were established as commercial joint-stock companies under peculiar conditions adapting them to the service of the state. Any dividends earned by them above 5 or 6% on their capital were to go to the State (in the first place to the Minister for War, to be applied to war purposes). In Austria the Government did not subscribe any of the capital, but the central boards were subjected to State supervision and their power of fixing prices was in many ways limited. These boards were now given the monopoly of the right to import certain wares (sometimes private buyers were allowed to purchase, but only on condition of selling the goods imported to the board); they were also entrusted with the reception of the instalments of raw materials already mentioned as released from bond in Germany. The activity of the central boards as purchasers in neutral countries did not last long; it came quickly to an end in 1915, especially after Italy's entry into the war.

Fresh tasks were, however, soon imposed upon them. The virtual stoppage of all supplies of raw materials from abroad necessitated the strictest economy in the use of those available at home, and this led to an elaborate system of Government control. Since expert advice was absolutely essential to the efficient working of such control, the task of carrying out the regulations as to the distribution of materials, etc., was entrusted to central boards under the form of war associations (*Kriegsverbände*), or economic associations (*Wirtschaftsverbände*), each controlling certain materials. The associations, to which the manufacturers using these materials had to belong, were directed by elected committees; at the head of each was an expert appointed by the Government, which was represented on the board by a commissioner exercising the Government's right of supervision. In addition to regulating the distribution of raw materials these boards exercised other useful functions, such as discovering fresh sources of supply, improving methods of production, etc. They also acted as receiving centres for goods imported from neutral countries, allied states or occupied territories. In this way there arose central boards for wool, cotton, oil and fat, hides and leather, and various metals—to name only the more important materials.

The control exercised by these boards was limited in scope and touched only comparatively narrow classes. It was otherwise with the control of foodstuffs, which was all-embracing. The problem in Austria, as elsewhere, was to keep the prices of the necessaries of life at a level low enough to enable the people to live. The attempt to fix maximum prices broke down, owing to the temptations to secret dealing, and, as in England, the card system had to be introduced.

Early in 1915 an institution was established for regulating the traffic in grain during the war (*Kriegsgetreide-Verkehrs-Anstalt*); it had been preceded by a central maize board, established to control the distribution of the maize contributed by Hungary.

The new institution was registered as a trader and was to be conducted on commercial principles, its expenses being covered by its receipts, and the State only guaranteeing it against eventual loss in order to secure the credit of the company. The principle of balancing expenditure and receipts was, indeed, soon abandoned, the State making advances to the institution in order that bread-stuffs might be sold under cost price. This institution, in the conduct of which officials and experts appointed by the Government took part, had complete control of all grain, flour, mills and bakeries. Its activities in fixing the price and quality of bread, etc., and in rationing, closely resembled those of the food controller in Great Britain (*see* FOOD SUPPLY and RATIONING).

This system of State control prevented industries which used grain as their raw material from buying in an open market, and in their case too it was found necessary to regulate supplies by means of an organization analogous to that of the economic associations already mentioned. In many cases these boards were established in connexion with the already existing trade associations (*e.g.* the Central Brewery Board in connexion with the Central Association of the Austrian Brewery Association), which set up their own distributing-stations and divided the raw material among producers according to a scale fixed by the Government, charging the producers a commission, in addition to the cost price, in order to cover costs. These boards also undertook other functions, such as introducing new methods of manufacture and supplying the workers in the munition factories with beer. Sugar and alcohol were also placed under the control of central boards, in connexion with existing organizations but with a certain independence: for instance, the Sugar *Kartel* ceased to exist, while the Central Sugar Board continued. The latter also managed the export of sugar, in return for which certain wares were imported.

Of particular interest were the purchasing associations formed during the war. In the autumn of 1915 the Ministry of the Interior established the "*Vom Ministerium des Innern legitimierte Einkaufsstelle m. C. H.*" (Purchasing station with limited liability licensed by the Ministry of the Interior), known as the "*Miles*," which was charged with the buying of goods in neutral countries. At first this organization acted as agent of the newly-established *approvisionment* departments; it was only later that it received the monopoly of the right to import certain articles, the Government at the same time placing at its disposal certain wares with which to pay for them. The prices fixed by the *Miles* for the sale of its wares were not at first interfered with; it was only later that its dividends were limited to 6%. It was then transformed into the "*Oezeg*" (*Oesterreichische Zentral-Einkaufsgesellschaft:* Austrian Central Purchasing Company), which was the very type of an "altruistic company." In addition to the dividend 5% was allowed for commission, office expenses and risk. By agreement with the Ministry of the Interior, as soon as the reserve exceeded by 10% the working capital (which was partly in shares, partly in bank advances) the company was to sell food under cost price; and this actually happened.

The system of regulation by central boards was severely criticised for incompetence and even for corruption, and sometimes justly; but on the whole it was amply justified by the urgent necessities of the times and by its results. Many other measures had also to be resorted to in order to maintain the industry of the country. Briefly, the duty of maintaining industries was made obligatory, and in the last resort the military authorities were empowered to take them over, though this was not likely to happen as long as the high prices continued and the Government supplied raw materials. Tillage was also made compulsory, but this had little effect on production owing to the shortage of labour, draft animals, manures and agricultural implements, together with the oppressive restrictions caused by the fixing of maximum prices.

All these measures could not alter the fact that the national economy became less and less equal to the tasks imposed upon it by the war. So soon as State control was applied to any article it could be taken as a sign that the supplies would soon come to an end, or at any rate were very restricted; and thus it was impossible to prevent the equipment of the army from becoming gradually more inadequate, and the provision both of the army and of the population behind the lines with all kinds of necessaries from being altogether insufficient; only wholly unsatisfactory substitutes could be provided, and the available provisions could hardly be made to go round. When the war came to an end Austria was almost completely stripped of many important commodities.

No better picture can be obtained of its overwhelming economic impoverishment than by studying the figures which show the decline in the crop returns for Austria, and taking into account the fact that imports from Hungary and the territories under military occupation naturally fell far below the proportion of foodstuffs formerly imported. Table X. gives the returns of the principal crops for Lower Austria according to the statistics of the Ministry of Agriculture.

TABLE X.—Crop Statistics.
(Thousands of tons.)

	1906–15*	1915	1916	1918
Wheat	118	80	53	54
Rye	303	212	110	133
Barley	95	74	65	47
Leguminous Crops	8	6	5	4
Potatoes	639	636	344	307

*Average.

In the other Crown lands the crops declined in the same proportion. The production of fodder also declined steadily, the number of cattle fell, and the army horses were insufficiently fed.

To these purely economic difficulties was added the growing opposition of the population to the measures of compulsion. This in part depended on national factors, which became more clearly visible as the situation of the Central Powers became more and more unfavourable, but it was in part due simply to the exhaustion due to economic need. Thus the spirit of the labouring classes became more and more inflamed, and at the beginning of 1918 the Government had the greatest difficulty in suppressing an anti-war agitation among the working classes, which assumed a threatening form. Movements were now unchained which were bound after the end of the war to leave their impress upon the political events and internal economy of the young Austrian republic (*see* AUSTRIA, REPUBLIC OF). (K. P.; R. STR.)

Finance and Banking.—The third licence granted to the Austro-Hungarian Bank expired on Dec. 31 1910. It was at first extended provisionally, as it was impossible to reach a settlement between Austria and Hungary regarding the continuance of common currency and banking arrangements. In Hungary a strong majority, which the Government could not afford to ignore, insisted on the formation of an independent Hungarian bank; on the other hand the advantages accruing to Hungary through the community of the financial and banking organization were quite obvious. There was an important divergence of opinion between Austria and Hungary concerning the constitution of the bank. Since the closing years of the 19th century the Austro-Hungarian Bank had pursued a policy which had in the main the object of making the Austrian *krone* a gold exchange standard. It was decided, however, by the Austrian financial authorities that the obligation of the Austro-Hungarian Bank to convert its notes into gold on demand should remain suspended as hitherto, owing to fear lest the renewal of the obligation of the bank to cash its notes in gold should lead to a rise in the rate of interest. Hungary, on the other hand, striving for access to the money markets of the West, desired that the obligation of the Austro-Hungarian Bank to cash its notes should be explicitly mentioned in the law, in order to make the public loans rank as easily negotiable securities on foreign *bourses*. In the banking law of Aug. 8 1911 a compromise was formed on the following lines. The suspension of cash payment by the Austro-Hungarian Bank was continued, but the bank was bound to provide, by every means at its disposal, that the value of its notes as quoted on foreign *bourses* should be permanently secured in proportion to the parity of the legal mint standard of the *krone* currency. Hungary's wishes were met by the introduction of a specially prompt procedure for the eventual future abolition of the suspension of the bank's obligation to cash its notes. By the same law, besides other less important provisions, the amount of the bank's tax-free issue of notes was raised from 400 to 600 millions of *kronen*, and the conditions formerly attached to the issue of 10 and 20 *kronen* notes were sensibly relaxed.

for setting industrial production going again in any way. Its first steps in war economy were confined to the sphere of finance and credit: the *bourse* was closed, and a moratorium announced. With regard to the latter, however, the requirements of industry were studied to a certain extent, in that the withdrawal of money from the banks was allowed, so far as it was necessary for paying wages and for the provision of working capital.

There was no revival of industry until the orders of the military authorities began to come in, which gave lucrative employment. In a short time, and without any pressure from the Government, but solely as a result of the favourable prices it offered, industrial conditions were completely transformed so as to meet the exigencies of the war. At first indeed, since the war was only expected to last a short time, there was little disposition to incur the heavy expenditure necessary in order to secure a share in the manufacture of war material; but this attitude was soon changed, and within six months factories everywhere had been adapted to the supply of munitions and all the variety of other things required by the Government for the armies. Industry was thus in many ways compensated for the paralysis of trade with private buyers in the home market and for the closing of foreign markets, and it would have been able to continue quietly on the old lines but for the emergence of a new factor which fundamentally altered the conditions. This factor was the rupture of communications with foreign countries, due in the earlier stages of the war to the limitation, and at one time the prohibition, of exports by neutral countries, the passing over of some of these countries to the enemy, and lastly the blockade by the enemy Powers, which increased in efficiency and made it more and more difficult to import the most essential commodities, until in the end it was almost impossible to obtain from abroad anything, needed either for the soldiers or the civilians.

In this respect Austria found herself in the same position as the German Empire; in fact, her position was in many respects considerably worse; many richly productive territories were temporarily occupied by the enemy; and as Austria was far less well provided with raw materials than Germany she was less in a position to produce goods for exchange. In addition to this there was another quite exceptional source of difficulties which had the most serious consequences for Austria, namely her relation with Hungary, due to the peculiar constitutional structure of the Austro-Hungarian Monarchy. The Hungarian Government could claim the right to take independent economic measures for her own territory in war-time; a joint arrangement was only possible for the territories of the Dual Monarchy—which were united for tariff purposes—by agreements between the Austrian and Hungarian Governments; and since neither Government was exclusively concerned to carry out an adjustment of economic conditions solely in accordance with what was necessary for waging war and holding out with the supplies at their disposal, but each had also to champion the interests of one half of the monarchy against the other, the negotiations between the two Governments were often attended with the greatest difficulties, and constantly ended unsatisfactorily. Hungary, in accordance with her economic situation, had always the advantage in these negotiations, since she was incomparably richer than Austria in foodstuffs, and the latter was constantly thrown back upon Hungarian supplies; and this superiority on the part of Hungary became more and more definitely pronounced in proportion as the provision of the necessities of life for the army and civil population became a steadily-increasing anxiety.

The more complete the economic isolation of the monarchy the more the lack of raw materials made itself felt, both for the manufacture of indispensable war supplies and for the feeding of the civil population. To prevent the war being brought to a premature end by dearth of supplies, the Government took measures, modelled on those adopted in Germany, for ensuring that necessary goods should be supplied to the proper quarters—whether the army authorities, manufacturers of war material, or consumers—and at a moderate price.

The quantity of raw materials which Austria had been in the habit of importing from abroad, and the quantity stored in the country at the outbreak of the war, were comparatively very small. The Austrian and Hungarian ports were of little importance as ports of entry for raw materials, the goods stored there being mainly from the Levant. On the other hand, wool, cotton, metals, etc., which came from overseas, were imported through German or Dutch ports, and were stored there, though often already in Austrian ownership. It was of the first necessity to assure the transport through Germany of these Austrian-owned goods, and an agreement with the German Government securing this was made. Agreements were also concluded by which a share of the goods owned by Germany was conceded to Austria.

It was next necessary to organize the purchase of goods in neutral countries. This was at first left wholly to private enterprise; but, as Austrian buyers not only competed with each other but also with buyers from other countries, this was bound to send up prices, while the interests of the State were subordinated to private gain. To meet this situation Germany set up central boards (*Zentralen*), and Austria followed suit, partly at the request of the German Government, which wished to avoid the competition of Austrian agents. Since the functions of these organizations were commercial, for which the regular Government officials were unsuited, they were established as commercial joint-stock companies under peculiar conditions adapting them to the service of the state. Any dividends earned by them above 5 or 6% on their capital were to go to the State (in the first place to the Minister for War, to be applied to war purposes). In Austria the Government did not subscribe any of the capital, but the central boards were subjected to State supervision and their power of fixing prices was in many ways limited. These boards were now given the monopoly of the right to import certain wares (sometimes private buyers were allowed to purchase, but only on condition of selling the goods imported to the board); they were also entrusted with the reception of the instalments of raw materials already mentioned as released from bond in Germany. The activity of the central boards as purchasers in neutral countries did not last long; it came quickly to an end in 1915, especially after Italy's entry into the war.

Fresh tasks were, however, soon imposed upon them. The virtual stoppage of all supplies of raw materials from abroad necessitated the strictest economy in the use of those available at home, and this led to an elaborate system of Government control. Since expert advice was absolutely essential to the efficient working of such control, the task of carrying out the regulations as to the distribution of materials, etc., was entrusted to central boards under the form of war associations (*Kriegsverbände*), or economic associations (*Wirtschaftsverbände*), each controlling certain materials. The associations, to which the manufacturers using these materials had to belong, were directed by elected committees; at the head of each was an expert appointed by the Government, which was represented on the board by a commissioner exercising the Government's right of supervision. In addition to regulating the distribution of raw materials these boards exercised other useful functions, such as discovering fresh sources of supply, improving methods of production, etc. They also acted as receiving centres for goods imported from neutral countries, allied states or occupied territories. In this way there arose central boards for wool, cotton, oil and fat, hides and leather, and various metals—to name only the more important materials.

The control exercised by these boards was limited in scope and touched only comparatively narrow classes. It was otherwise with the control of foodstuffs, which was all-embracing. The problem in Austria, as elsewhere, was to keep the prices of the necessaries of life at a level low enough to enable the people to live. The attempt to fix maximum prices broke down, owing to the temptations to secret dealing, and, as in England, the card system had to be introduced.

Early in 1915 an institution was established for regulating the traffic in grain during the war (*Kriegsgetreide-Verkehrs-Anstalt*); it had been preceded by a central maize board, established to control the distribution of the maize contributed by Hungary.

spite of his great age brought about a transformation, and the architect Otto Wagner (1841–1918), who, though his roots were set in the age of Francis Joseph, became the leader of the moderns in Vienna.

Side by side with these artists, who, in spite of their international features, devoted their talents to Austria, were others who split away from their native land and became completely identified with foreign art, for example: Alphons Mucha (b. 1860), who became a French decorative artist; the painters Charles Schuch (1876–1903) and Emil Orlik (b. 1870); the sculptors Hugo Lederer (b. 1871) and Hans Metzner (1870–1919); and the architect Josef Olbrich (1867–1908), who have all more importance in the development of German art in general than of Austrian art.

Meanwhile there arose various national schools, which developed with energy their racial peculiarities. The young Poles, united in the society called the *Sztuka*, endeavoured to depict Slav gaiety in a riot of gaudy colour (Chelmonski, Mehoffer, etc.); in like manner the Slovak Joza Uprka (b. 1862) exploited his native land, his materials being peasant customs and types and the peasant's love of colour. Frantisek Bilek (b. 1872) mirrored in mighty contours the ardent faith of the Slav peoples, while Jan Stursa, endowed with equal power, refined it into an art of truly European quality. In contrast with these two Czech sculptors may be placed the highly gifted Southern Slav Mestrovic, who expressed in his art the refractory energy and wild fanaticism of his race. Among German-Austrian artists the originality of the Tirolese Albin Egger-Lienz (b. 1868) deserves special mention, for in it the Tirolese element plays an important part.

In Vienna the leading personality of his generation was Gustav Klimt (1862–1918); his very delicate decorative art, his subtle taste in colour, his inclination towards industrial art, make his painting so Viennese that it would hardly be comprehensible in other surroundings. A pendant to him is the architect Josef Hoffmann (b. 1869), who originated in the school of Otto Wagner, whose stiff principles he softened, however, by his richer taste (*e.g.* the Stoclet House in Brussels); the tendency towards decorative and industrial art which Klimt had revived in Vienna was turned into a systematic school by Hoffmann. In theatrical decoration, in domestic architecture, in all branches of the handicrafts, Vienna became a leading centre of the moderns, the "Viennese Workshops" (*Wiener Werkstätte*) and the "Austrian Craft Guild" (*Österreichische Werkbund*) being the centre of their activity. A leading figure among the younger generation of artists, after the war, was Oskar Kokoschka (b. 1888). (H. Tk.)

Literature and Drama.—Between 1910 and 1920 new tendencies and personalities came into the literary foreground in Austria, and moreover death made many gaps in the ranks of the leading representatives of the older traditions. In 1916 died Marie von Ebner-Eschenbach (*see* 8.843*). Born in the same year as Francis Joseph (1830), she had continued her literary activity to the very end of her life. In 1915 she published the sketches entitled *Stille Welt*, and from her literary remains appeared in 1916 *Erinnerungen an Grillparzer* and *Blätter aus einem zeitlosen Tagebuch:* prose poems, satirical attacks on Ibsen, Hauptmann and the modern school, for whom she had no sympathy. Her enthusiasm for Tolstoy was correspondingly great, and among her successors she marked out for special praise Enrica Handel Mazzetti, with whom she carried on a correspondence which was published under the title of *Der Dichterinnen stiller Garten.* In 1918 died the Styrian dialect poet Peter Rosegger (*see* 23.734). He too delighted in creation till the end of his life, and was occupied in revising his collected works for an edition in 40 volumes. *Rückblicke auf den Schauplatz des Lebens: Abenddämmerung* appeared posthumously in 1919; it deals with questions of time and eternity, religious, social and political problems, and the characters of eminent people, *e.g.* Schiller and Francis Joseph. His greatest successor as a dialect poet he held to be the Tirolese dramatist Karl Schönherr. During the decade several other notable writers died. Count Albrecht Wickenburg (1838–1912), husband of the poetess Almasy-Wickenburg, was a fine lyrical poet who made a masterly translation of Shelley's *Prometheus.* Freiherr Alfred von Berger (1853–1912), important as an essayist and playwright, founded the Deutsches Schauspielhaus at Hamburg, and ultimately became director of the Burgtheater. Max Burckhard (1857–1912), a distinguished jurist, who was director of the Burgtheater for eight years, was a champion of Ibsen, Hauptmann, Schnitzler and Anzengruber, and patron of the greatest actors of the rising generation—Hedwig Bleibtreu, Lotte Medelsky, Mitterwurzer and Kainz; he was active as a critic, dramatist and story-teller, but the artistic merit of his work was unequal. In 1917 died Bertha von Suttner, authoress of the novel *Die Waffen nieder!*, well known as a protagonist of the League of Peace, and winner of the Nobel prize. The Zionist Hugo Zuckermann (1881–1917), whose song, *Drüben am Wiesenrand sitzen zwei Dohlen*, was much sung at the beginning of the World War, fell in battle. Peter Altenberg (1859–1919) died at the age of 60; he was equally original in his life and his art, and his books, *Wie ich es sehe, Was der Tag bringt, Semmering*, etc., have a highly personal touch.

In spite of these losses there was no lack of talent in Austrian literature, for many followed in the footsteps of their predecessors but most of them sought and found ways of their own. The creations of Ibsen, Zola, Maeterlinck, Dostoievsky, Tolstoy, Shaw and Strindberg had their influence on the younger generation. Modern and ultra-modern tendencies, the new romanticism, symbolism, occultism, expressionism, took the place of realism, naturalism and impressionism. The partisans of Stirner and Nietzsche, the *Sturm und Drang* school, lost all sense of reason and moderation. Far removed from these wandering fires, and yet receptive to the subtle innovations of Ibsen and Hauptmann, there developed the most powerful of contemporary German-Austrian writers, Karl Schönherr. Born in 1830 at Axams near Innsbruck, the son of a schoolmaster, he spent his life in Tirol, going to the university of Vienna, where he qualified as a doctor. In 1895 he first appealed to the public in his dialect poems, *Innthaler Schnalzer*, and his sketches *Allerhand Kreuzköpf'.* His drama, *Judas von Tirol*, was an unsuccessful attempt to represent the betrayer of Andreas Hofer on the stage. *Die Bildschnitzer* and *Sonnwendtag* met with success both at the Volkstheater and the Burgtheater. In 1907 followed the tragi-comedy *Erde*, in which the principal rôle, that of the old peasant Grutz, was splendidly played by Josef Kainz, and is a finely conceived type. The character was so convincing that the original of old Grutz was looked for in every walk of life and mistakenly supposed to be Francis Joseph, since he kept the impatient heir, Francis Ferdinand, waiting in vain for the throne. After a fairy play, *Das Königreich*, Schönherr composed his tragedy, *Glaube und Heimat*, a national-historical drama which gave a vivid picture of the Reformation and Counter-Reformation and the proscription of Protestants in the Alpine regions, and in spite of ultramontane agitation was played hundreds of times with the greatest success. In 1915 Schönherr completed his technically unique drama for three characters only, *Der Weibsteufel;* it was violently attacked by ecclesiastical fanatics, and its morality was defended by the poet in an indignant answer to the bishop of Munich. In the middle of the war Schönherr published the drama on the subject of Hofer which he had begun in 1909, *Volk in Not*, a German heroic poem, which represented so impartially the light and dark sides of the Tirol's struggle for freedom that the military censorship of Berlin and Vienna, on trifling pretexts, for years prevented this masterpiece from being produced. Schönherr's remaining plays are: *Fruchtbarkeit*, the tragedy of a childless peasant woman; the *Kindertragödie*, again for three characters only; and two pessimistic pictures of academic life, *Narrenspiel des Lebens* (1918) and *Der Kampf; ein Drama geistiger Arbeiter* (1920). Schönherr's stories, *Caritas* (1907) and *Aus meinem Merkbuch* (1911), are worthy to rank with his plays, and in their sober form, grim humour and tragic reticence bear the true impress of the Tirolese race.

Fundamentally different in method and art is the most notable Austrian dramatist next to Schönherr, Arthur Schnitzler.

* *These figures indicate the volume and page number of the previous article.*

Schönherr in his substance and method everywhere proclaims himself of the Alps; Schnitzler always shows himself a citizen of the Viennese capital and a man of the world. Schönherr is a moralist, Schnitzler a sceptic. Whether in jest or in earnest, both as a writer of short stories and verse drama, he is principally preoccupied with the love motive; *Anatol*, a set of dialogues representing the world of pleasure and inspired by an exuberant wit recalling Maupassant, was followed in 1895 by his best youthful production, *Liebelei*, and by a series of plays which discuss in sophisticated dialectic the problems of love and marriage. In *Litteratur der Bohême* and *Comtesse Mizzi* he attacks with exuberance and wit the highest Austrian aristocracy. In the grotesque *Der grüne Kakadu* he shows an avenging doom ready to break forth boldly over the unconscious *ancien régime* from a low drinking-den, on the day of the storming of the Bastille. The historical piece, *Der junge Medardus*, has its scene laid during Napoleon's stay at Schönbrunn; it is a picture of the times, in which he does not fail to include the episode of Napoleon kicking his hat. *Professor Bernhardi* is a satirical picture, drawn by a master hand, of Austrian university and parliamentary life; it was played hundreds of times in Berlin, but under the Habsburg Monarchy it was forbidden by the censor owing to its only too true reflection of insignificant ministers and party leaders; it was not till the republic that the ban was removed from this comedy. As a story-teller Schnitzler achieved uncommon success when most happily inspired (*Leutnant Gustl*, 1901; *Masken und Wunder*, 1912). His novel, *Der Weg ins Freie* (1908), has the Jewish question as its subject.

The Jewish problem was also treated, with far deeper penetration, by Schnitzler's friend, Richard Beer-Hofmann, who had been silent since the appearance of his *Graf von Charolais* half a generation earlier, in his Biblical drama *Jaakobs Traum*, which both in its form and contents is of lasting value. Another close friend of Schnitzler, Hugo von Hofmannsthal, the much-fêted leader of the aesthetic school of lyrical poets, wrote the libretto for Richard Strauss's *Elektra, Der Rosenkavalier* (1911), *Joseph, Ariadne auf Naxos* (1912), *Die Frau ohne Schatten* and so shared in the world-wide fame of the musician. He gave a new version of *Alkestis* and of the mediaeval drama *Everyman* (*Jedermann*). Widely read in the literature of the world, he formulates his opinions in refined though sometimes over-elaborate prose: the earlier collections of shorter works were supplemented after the war by several volumes of *Rodauner Nachträge*. The former protagonist of this group, Hermann Bahr, suffered from an excess of versatility. The theatrical success of his much-acted *Concert* (1909) was not repeated in the case of any of his later pieces. In his *Erinnerung an Burckhard* (1913), *Aufsätze für Religion und Philosophie, Inventur, Expressionismus* (1917), and the many volumes of his *Tagebuch* he aimed at being an index to all the vicissitudes in art and life. He sprang from one extreme to another; once a follower of Marx, a free-thinker and an anarchist, after the World War he was for the moment preaching reaction in science and uncompromising Catholicism. Hans Müller (b. 1882) is a writer of verse drama whose downright methods hit the taste of the masses. His drama *Könige* (1915), which enjoyed the special patronage of the German emperor and dealt ostensibly with the feud between Louis of Bavaria and Frederick of Austria, but in reality with the rivalry of the Hohenzollerns and Habsburgs, had an enormous popular success. He modelled himself on Sudermann in one piece, *Der Schöpfer*, the hero of which is the self-confident inventor of a serum; a weaker effect was produced by his play *Sterne*, which explains Galileo's retraction as due to timidity. On the other hand his *Flamme* (1920–1), which represents on the stage the life of the *demi-monde*, ran for months in the great theatres of Berlin and Vienna, in spite of all the [illegible] of the critics.

Austrian achievements in lyrical poetry were no less noteworthy than in the drama. According to the testimony of the German Soergel, the young lyric poets of the time venerated above all others two poets, Dehmel, the poet of will, and Rainer Maria Rilke (b. 1875), the poet of mood. They regard Rilke's bewitching melodies, his delicacy of observation, his mystic ardour, his absorption in God, as the highest revelation of their kind. Rilke himself, in his autobiographically-coloured *Aufzeichnungen des Malte Laurids Brigge* (1910), thus defines his poetic mission: "Verses are not sensations, as people think—they are experiences. For the sake of a single verse one must see many towns, men and things, one must know the animals, one must feel how the birds fly and in what wise the little flowers open in the morning."

Regardless of Rilke, Stefan George, or Hofmannsthal, the singers of the older generation continued to write lyrics in the traditional form: for example, the Styrian pastor Ottokar Kernstock (h. 1878), canon of Vorau, *Aus dem Zwingergärtlein*, and with Rosegger, *Steirischer Waffensegen* (1915), *Schwertlilien aus dem Zwingergärtlein, Kriegsgedichte*. In Tirol too there was an ecclesiastic, Brother Williram (Müller), who wrote patriotic songs during the World War. Arthur von Wallpach (b. 1866) and Franz Karl Ginzkey (b. 1871) also preserved their old skill. A new note was struck both in war and peace hy Anton Wildgans (b. 1881), who put forth, in quick successsion to his first work, *Herbstfrühling* (1909) and his self-revealing *Sonette an Ead* (1913), *Infanterie, Mittag*, and several dramas with a lyric quality, *Armut, Liebe*, and *Dies Irae*, which led to his appointment as director of the Burgtheater.

The greatest talent among the younger poets was Franz Werfel (b. 1890), who in his version of the *Trojan Women* of Euripides (1917) vividly painted the curse of war, and afterwards, like Albert Ehrenstein (b. 1886), openly confessed himself a violent opponent of militarism. But the most outspoken condemnation of the war party, military or civil, was pronounced by Karl Jeremias Kraus (b. 1874), editor of the review *Die Fackel*, a very considerable satirist and an unshrinking adversary of social abuses in his books, *Sittlichkeit und Criminalität* (1909), *Die chinesische Mauer* (1910), *Pro domo et mundo* (1912), *Kultur und Presse* (1915). In 1919 he displayed, as in a mighty fresco, "the last days of humanity" (*Die letzten Tage der Menschheit*), a series of scenes arising during the World War, which, changing from wild mockery to awful tragedy, pictures the atrocities and misdeeds of army commanders and diplomatists, the credulity of the masses, the barbarity of military justice, the brainlessness and heartlessness of those in high places. Exaggerated in some details, and on the whole over-severe to his native land, *Die letzten Tage der Menschheit* is none the less, in spite of all reservations, a considerable literary achievement, a picture of the times having the value of a document.

Among the older generation of Austrian novelists we may mention Emilie Mataja (Emil Marriot, b. 1855) for descriptions of ecclesiastical and social life; Adam Müller-Guttenbrunn (b. 1852) for novels dealing with life in the Banat; and Stüber Gunther (b. 1872), the successor of Pötzl and Chiavacci among Viennese humorists. Among the most remarkable artistically are Enrica Handel Mazzetti (b. 1871) and Rudolf Hans Bartsch (b. 1873). Baroness Handel, who had been given a strictly religious education by the "englische Fräulein" at Sankt Pölten, gave in her principal works—*Meinrad Helmpergers denkwürdiges Jahr* (1900), *Jesse und Marie* (1906), *Die arme Margaret* (1910), *Stephana Schwerdtner* (1913), *Ein deutscher Held* (1920)—propagandist stories in which free-thinkers, Protestants and blasphemers are led by their tragic experiences to become Catholics. The action takes place sometimes in the 18th century, sometimes at the time of the Counter-Reformation, and in *Ein Deutscher Held* in the days of the Archduke Charles. Capacity for drawing convincing historical pictures here goes hand-in-hand with the gift of dramatic intensity. Her Catholic ideas do not make the authoress unjust to heretics, but she has a fatal taste for spiritual and physical torture, and wallows in scenes of blood and torment. Bartsch, originally an officer, won his first success with *Zwölf aus der Steiermark*, which was followed by many others, the greatest of which was *Schwammerl*, a novel about Franz Schubert. More closely knit in his technique is Jakob Wassermann, born at Fürth in 1873, a precisian in form and a virtuoso in language; and richer in ideas is Erwin Guido Kolbenheyer (b. 1878), notably in his novel about Spinoza and Paracelsus.

Up to the end of the World War the Vienna Burgtheater had still the ambition of ranking with the Comédie Française as the first theatre of the continent of Europe. The dialect drama, to which Raimund, Nestrey and Anzengruber had contributed, still had the reputation of being, as Platen said, a popular form of comedy which is more comic than the whole of the German theatre. In the meantime the Burgtheater lost its brilliant *doyen* Bernhard Baumeister (1828–1917), and its greatest master of declamation, the famous emotional actor, Josef Kainz (1858–1918). Finally Alexander Girardi (1850–1918) died too, the popular Viennese comedian, whose gift for music and improvisation showed him no unworthy representative of the Italian tradition.

See Albert Soergel, *Dichtung und Dichter der Zeit* (1916); Oscar F. Walzel, *Die deutsche Dichtung seit Goethes Tod* (1919); Alfred Maderno, *Die deutsch-österreichische Dichtung der Gegenwart* (1920).
(A. B.)

History.—During 1910–20 the influence of the work of Theodor von Sickel (1826–1908), and of the Austrian Institute for Historical Research, which had been brought by him to a high pitch of excellence, was shown in a marked activity on the part of Austrian historical writers. In the footsteps of Sickel, and also of his great contemporary Julius von Ficker (1826–1902), came their disciples Engelbert Mühlbacher (1853–1903) and Emil von Oltenthal (b. 1855); Oswald Redlich (b. 1858), with his *Rudolf von Habsburg;* Alfons Dopsch (b. 1868), with his *Wirtschaftliche Entwicklung der Karolingerzeit* (2. vols., 1912–3) and *Wirtschaftliche und soziale Grundlagen der europäischen Kulturentwicklung* (2 vols., 1918–9); Ludo Moritz Hartmann (b. 1865) with his *Geschichte Italiens*, etc.

A number of the historians who came from the school of Sickel turned to modern history, under the influence of Ottokar Lorenz (1832–1903). Distinguished among them by his gift for vivid exposition was Heinrich Friedjung (1851–1920), notable for his *Der Kampf um die Vorherrschaft in Deutschland* (2 vols., 11th ed. 1919), *Oesterreich, 1848–1860* (2 vols., 4th ed. uncompleted), *Das Zeitalter des Imperialismus, 1884–1914* (vol. i., 1919), *Gesammelte Aufsätze* (1910). A rich literary activity was displayed by August Fournier (1850–1920), whose biography of *Napoleon* (3rd ed., 1913, Eng. trans. 2nd ed. 1911) became widely known even beyond the sphere of the German-speaking public. From the pen of A. F. Pribram there appeared, among other works, the second volume of *Die englisch-oesterreichischen Staatsverträge* (1913), and *Die geheimen politischen Staatsverträge Oesterreich-Ungarns 1879–1917* (1920; English trans. by A. C. Coolidge, 1920).

Worthy of note among the younger historians trained at the Institute were Hans Uebersberger (b. 1877), with *Russlands Orientpolitik in den letzten Jahrhunderten* (vol. i., 1913); H. R. von Srbik (b. 1878), with *Wallenstein's Ende* (1920); Wilhelm Bauer (b. 1877), with *Die öffentliche Meinung auf historischer Grundlage* (1917); Viktor Bibl (b. 1870), with *Der Tod des Don Carlos* (1919); H. Kretschmayer (b. 1870), with his *Geschichte Venedigs* (2nd vol. 1920). The methodical research into texts inaugurated in Austria by Sickel and Ficker produced valuable fruits in the sphere of German and Austrian legal and constitutional history. Prominent among the workers in this field were Arnold Luschin von Ebengreuth (b. 1841); H. von Voltelius (b. 1862) and Siegmund Adler (1813–1920).

Among historians unconnected with the above-mentioned movement, Josef Freiherr von Helfert (1820–1910) was distinguished by a rare devotion to work; a man of great talents, he crowned his life-work by a history in two volumes of the Austrian Revolution of 1848. Ludwig von Pastor (b. 1854) continued his widely read *Geschichte der Päpste* (5th vol., 1920); Eugen Guglia (1855–1918) published a book on *Maria Theresa* (2 vols., 1917). In the sphere of Slavonic history the unfinished *Geschichte Serbiens* of J. Jirecek (1857–1918) is also worthy of note. As an economic historian Karl Grünberg (b. 1891) established his reputation during the decade.

The eminent Viennese professor of constitutional law, Josef Redlich (b. 1869), widely known abroad through his masterly works on English local government and English parliamentary procedure, published in 1920 the first volume of *Das oesterreichische Staats- und Reichsproblem*, a history of the internal policy of the Habsburg Monarchy from 1848 to the break-up of the empire. This first volume brings the account down to 1861.
(A. F. Pr.)

Foreign Policy, 1909–18[1]

Austro-Hungarian foreign policy in the crucial decade which, through the World War, led to the downfall of the empire, can only be understood by recalling the main historical problem that confronted the old monarchy.

Rivalry with Russia in the Near East.

Since the foundation of the German Empire and the kingdom of united Italy an extension of Austria-Hungary towards the S. and W. of Europe had become impossible. Only in the S.E. could she still count on an expansion of her territory and power. Thus from the seventies of the 19th century onwards the policy of the leading Austro-Hungarian statesmen had taken the direction indicated by geographical conditions. In this Austria had to reckon with the opposition of Russia, which, with the pressing back of Turkish influence, had become her great rival in S.E. Europe. In order to maintain herself as a Great Power, make her frontier secure against hostile attacks, and suffer no restriction on her further development, she could not allow another Great Power to command the Danube and its mouths, and arrogate to itself the hegemony of the Balkan peoples. This political and economic opposition between the Habsburg Monarchy and Russia was reënforced by opposition of an ethnical and cultural nature. In view of this struggle against a competitor far superior in population and military strength, Austrian statesmen had sought an alliance or understanding with those European states whose interests appeared to run parallel with their own. It was to the benevolent attitude of Germany and England that Austria had owed the occupation of Bosnia and Herzegovina and the right of maintaining garrisons in the Sanjak of Novibazar—the door to the Near East and the first step towards an expansion of Austria-Hungary's sphere of influence in the Balkans, which promised rich prospects, but at the same time an increase in Russian hostility.

From the early eighties of the 19th century Andrassy's successors did indeed try to arrive at a *modus vivendi* with Russia, and were zealously seconded in this effort by Prince Bismarck, who wished to hold the balance between his two allies. Numerous crises were successfully overcome, but the conflict of interest remained, and was especially heightened after the Russo-Japanese War (1904–5) had ended unfavourably for Russia. Russian statesmen renounced the policy, which they had followed for a time, of getting to the "warm ocean" in the Far East, and returned to the one which had been followed by Peter the Great and Catherine and never entirely given up, the goal of which had been the conquest of Constantinople and the command of the Dardanelles. The constantly increasing differences between Germany and the Western Powers, and the advances made by the latter towards friendship with the court of the Tsar, led in 1907–8 to a close entente between Russia and England, and hence to the development of the long-standing alliance between Russia and France into a Triple Entente.

Aehrenthal's Policy.

Baron Aehrenthal, who from the autumn of 1906 had directed the foreign policy of the Habsburg Monarchy, recognized the threatening danger, which became greater and greater as the internal affairs of the Turkish Empire assumed a more and more critical aspect. This empire he wished to preserve, if it could by any means be done; but in the event of its final liquidation he was firmly determined to safeguard the interests of Austria-Hungary. It was above all necessary to make sure of the possession of the occupied prov-

[1] The article under Europe, written from a British historian's point of view, should be read for a somewhat different perspective of the European situation which resulted in the World War. See also Serbia. The account given here naturally reflects, in various aspects, the point of view of an Austrian historian.—(Ed. *E. B.*)

inces of Bosnia and Herzegovina, which had been under Austro-Hungarian government for 30 years past. The Young Turk Revolution, in July 1908, served as a pretext for carrying into effect the annexation of these territories, which had been planned long since. It happened opportunely that at this very time Russian statesmen wished to effect the realization of their designs on the Dardanelles. Isvolsky, who directed Russian foreign policy, knew indeed that it would not be easy to win over Great Britain to his plan. But since he believed himself sure of French support, he hoped to achieve at least his immediate aim, the opening of the straits to Russian ships-of-war, so soon as he had come to an understanding with the Central Powers, and especially with Austria-Hungary. During the negotiations entered upon, on Aehrenthal's initiative, between the Cabinets of Vienna and St. Petersburg, Isvolsky expressed his consent to the annexation of Bosnia and Herzegovina in the event of the Vienna Government's falling in with his plans as to the straits question. Aehrenthal seized upon this proposal, for he hoped that the annexation of these provinces would enable him to take active measures in face of the Greater Serbia movement.

At the beginning of July 1908 Isvolsky handed in at Vienna a memorandum which guaranteed to the Habsburg Monarchy, besides Bosnia and Herzegovina, the greater part of the Sanjak of Novibazar as well. Aehrenthal accepted Isvolsky's offer in so far as it applied to the annexation of Bosnia and Herzegovina; but he demanded the same right for the warships of Rumania and Bulgaria as for those of Russia, and in addition a guarantee against an attack on Constantinople by a Russian fleet entering the Bosporus. In return he was ready to give up the Sanjak and the rights appertaining to Austria-Hungary in Montenegro, and therefore the plan of an advance on Salonika, the seizure of which Andrassy had had in view as the next objective in Austria-Hungary's policy of expansion in S.E. Europe. On Sept. 15 Aehrenthal met Isvolsky at the château of Buchlau in Moravia, informed him of the impending Austrian annexation of Bosnia and Herzegovina, and promised him in return a free hand in his proceedings with regard to the question of the Dardanelles. The two ministers promised each other mutual support; Aehrenthal renounced the Sanjak of Novibazar, as a set-off for which Isvolsky gave a promise that Russia would not take possession of Constantinople. A European conference was to give its sanction to their settlement. A binding written agreement was contemplated, but was not arrived at on this occasion.

When, however, at the beginning of Oct. 1908 Francis Joseph publicly announced the annexation of Bosnia and Herzegovina as a *fait accompli*, a storm of indignation burst forth in many quarters. It was insisted, especially in England, that agreements settled by international treaties could only be modified with the agreement of all the contracting Powers. Both in Paris and in London, where Isvolsky had betaken himself in order to obtain the consent of the Western Powers to the measures which he had concerted with Aehrenthal, he met with a decided refusal. Disappointed in his expectations, he now declared that he had been led astray by Aehrenthal.

Effect on the International Situation.

Serbia lodged a protest against the annexation of Bosnia and Herzegovina, demanded autonomy for these territories under the guarantee of the Great Powers, and a port on the Adriatic for Serbia, with a strip of territory to connect it with Serbia. Since Austria-Hungary showed no inclination to take these demands into consideration, Serbia now began to strengthen her military forces. At the same time a violent anti-Austrian movement began to make itself felt in Turkey. All goods coming from Austria-Hungary were boycotted, and Austro-Hungarian traders living in Turkey were subjected to annoyance. Bulgaria, whose prince, Ferdinand of Coburg, had assumed the royal crown on Oct. 5 1908, also took sides against Austria-Hungary. Aehrenthal had made himself personally offensive to that country, which now entered into negotiations with Russia and Serbia. In Italy, too, a hostile tendency towards Austria gained the upper hand. Victor Emanuel III described the annexation of Bosnia and Herzegovina as a blow at the Treaty of Berlin, and Tittoni, who had spoken on Oct. 7 in terms favourable to the annexation, declared in his great speech in the Consulta at the beginning of Dec. 1908—in contradiction with the tenor of a letter which he had addressed to Aehrenthal on Oct. 4—that he had entered into no engagements with regard to it. The nationalist press and the irredentists fanned the flames, and in the Austrian Parliament the Slavs, and above all the Czech leaders, raised loud complaints.

But Aehrenthal remained firm. He was convinced that Russia, which had not yet recovered from the defeat which she had suffered in the Russo-Japanese War, would not draw the sword, and that he would therefore succeed in achieving his ends without bloodshed. His own efforts were directed towards the preservation of peace. In this point of view he was at odds with a powerful party, led by Conrad von Hötzendorff, chief of the Austro-Hungarian general staff, which was in favour of a decision by force of arms. In order to meet Russia's views Aehrenthal expressed his consent to the convening of a European conference, but insisted at the same time that he could only promise Serbia and Montenegro economic compensations, and made it a condition that the question of Austria-Hungary's sovereignty over Bosnia and Herzegovina should not be discussed at the conference, but only taken cognizance of by it. Aehrenthal's attitude aroused violent indignation in London and Paris. But since Germany resolutely took its stand on the side of the Habsburg Monarchy, France, with an eye to her Moroccan interests, only gave a lukewarm support to the Russian demands; and Isvolsky found himself compelled to beat a retreat. As early as Dec. 1908 he agreed that the conference should recognize the annexation of Bosnia and Herzegovina after a previous discussion of the matter had taken place between the several Cabinets. Meanwhile Sir Edward Grey, the English Secretary of State for Foreign Affairs, advised the Turkish Government to give their consent to the annexation of Bosnia and Herzegovina to be bought by a proportionate cash indemnity. Aehrenthal fell in with a suggestion in these terms, and on Feb. 26 1909 concluded an agreement with Turkey which secured to the Sultan, in return for his recognition of the annexation of Bosnia and Herzegovina by Austria-Hungary, a considerable sum of money in compensation for Ottoman State property in the annexed provinces. In the course of the month of March the negotiations as to the form of consent to the annexation to be given by the Great Powers concerned were brought to a conclusion. It was to be effected by official declarations on their part, a European conference being avoided. On March 24 declarations in this sense were handed in at Berlin and Vienna by the Russian Government; those of England followed on March 28.

Stubborn Attitude of Serbia.

The danger of an Austro-Serbian war, which for some time had appeared inevitable, had fortunately passed by. Even after the settlement of the Austro-Turkish conflict the Serbs remained stubborn; Aehrenthal, however, wanted to avoid war, and now, as before, hoped to reach his goal by calm firmness and conciliation. At the beginning of March 1909 he declared that Serbia, in order to avoid the humiliation of having her fate settled by the statesmen of Vienna, might submit to the decision of the Great Powers. But the Serbian Government declined, and continued to arm. The Cabinet of Vienna then decreed that the troops in the S.E. of the Monarchy should be reinforced. Isvolsky now saw that Francis Joseph was in earnest. Since he could not venture on war, he accepted the proposal of the German Imperial Chancellor, Bülow, that Russia herself should use her influence over Serbia in the direction of moderation. On Great Britain's initiative negotiations were entered upon with the Government of Vienna, which led to the drafting of a note which should secure to Austria-Hungary the satisfaction which she demanded.

Submission of Serbia.

After overcoming great difficulties it was possible to effect an agreement. On March 31 the Serbian Government handed in a note at Vienna in which it declared that Serbia had not suffered any injury to her rights through the annexation of Bosnia and Herzegovina by Austria-Hungary, and promised to change the attitude which she had hitherto taken towards the Habsburg Monarchy, to maintain

good neighbourly relations with the monarchy, and to reduce her army to the footing of the previous year (1908). In so doing Serbia submitted to the behest of the signatory Powers, but at the same time to the will of Austria-Hungary. Montenegro thereupon followed suit. The event was a victory for Achrenthal, but a pyrrhic victory, in that through it was effected the cleavage of Europe into two hostile camps. Russia now broke definitely with Austria-Hungary and became increasingly hostile to German policy, while England recognized with increasing clearness the significance of the Southern Slavs in the struggle against Germany, and especially of Serbia as a battering-ram against Germany's ally, the Habsburg Monarchy.

Triple Entente Reenforced.

Two other events led to a further strengthening of the Triple Entente. One was the *rapprochement* between Russia and Italy, made manifest by Nicholas II.'s visit to Racconigi (Oct. 24 1909); the other was the secret treaty concluded in Dec. 1909 between Russia and Bulgaria, which ranged the latter in the Russian sphere of influence, and contained among other things the declaration that the realization of the ideals of the Slav peoples in the Balkan peninsula would only be possible after a favourable outcome of Russia's contest with Germany and Austria-Hungary.

Aehrenthal's Efforts for Peace.

Yet at this time these opposing tendencies did not come out into the open. The Central Powers sought rather to overcome them. At the beginning of the year 1910 negotiations took place with Russia which were intended to further the establishment of better relations. After hopeful preliminaries they split on the irreconcilability of their conflicting interests. Aehrenthal's efforts at Rome seemed to meet with more success. He was able at the end of 1909 to arrive at an agreement with the Italian statesmen on the Albanian question, by which further friction between the two states, who were rivals in this quarter, should be avoided. In subsequent conversations which he held on frequent occasions in 1910 with the Italian Foreign Minister, San Giuliano, measures were considered which should smooth the way towards the establishment of friendly relations between the Cabinets of Vienna and Rome. In the years 1910 and 1911, moreover, Achrenthal was eagerly striving to do everything for the maintenance of peace. He endeavoured to reconcile the differences which were forever cropping up anew between England and Germany. In order to win over Rumania and conciliate Serbia, commercial treaties were concluded with them. In the interest of peace, too, he placed no obstacle in the way of the assumption of the royal style by the Prince of Montenegro (Aug. 29 1910). Yet Achrenthal kept his aim steadfastly in view: namely, the upholding of Austria-Hungary's interests in the Near East; and he left the Balkan peoples in no doubt that he would not be a peaceful spectator of the downfall of Turkey. He was in a difficult position when, in the autumn of 1911, Italy seized the opportunity for taking possession of Tripoli. A strong party, headed by the chief of the general staff, Conrad von Hötzendorff, held that the moment had arrived for coming to a reckoning with their faithless ally. In any case they wanted to use this favourable opportunity for assuring to Austria-Hungary the hegemony of the Balkans. But Achrenthal, supported by Francis Joseph, stood up for the maintenance of the Triple Alliance. He even held that it was in the interest of the Habsburg Monarchy that Italy's imperialistic aspirations should find satisfaction on the south of the Mediterranean. He therefore asked Italy, in leaving her a free hand in Tripoli, not to interfere with the designs of the Vienna Cabinet in the Balkan peninsula. Also he requested the withdrawal of the Italian fleet from the coast of Albania, and protested against Italian designs on Salonika.

Aehrenthal Succeeded by Berchtold.

The fact that Aehrenthal gained his ends by these demands confirmed him in the idea that he had hit upon the right way, and increased his hopes of being able to guard Austria-Hungary's interests in this difficult crisis without resorting to arms. Aehrenthal's death (Feb. 17 1912) was therefore a heavy loss to the Habsburg Monarchy, which made itself all the more felt since just at that time new dangers were arising for it in S.E. Europe. His successor as Austro-Hungarian foreign minister was Count Leopold Berchtold, who had formerly been ambassador at St. Petersburg.

The Balkan League.

The Italo-Turkish War, and especially the closing of the Dardanelles at the instance of the Turks, had done severe harm to Russian trade, and increased the desire of Russian statesmen to gain command of the Black Sea. It was widely held, too, that this was a favourable opportunity to bring about a Balkan alliance under Russian leadership, which should make it possible for Russia, as protector of the Slav peoples of the Balkans, to take possession of Constantinople. Hartwig, the Russian minister in Belgrade, was particularly active in this direction. Other circles, led by Charykov, the Russian ambassador in Constantinople, thought it possible to attain the same end by other means. They wanted to preserve Turkey, but to make her Russia's vassal. She was to be admitted to the Balkan alliance and, in return, to allow the Russian fleet a free exit to the Mediterranean. But Charykov's efforts failed. Turkey refused; and in March 1912 Charykov had to leave Constantinople. The old plan of forming a Balkan alliance against Turkey was now taken up again. The greatest difficulty in its way was the jealousy between the Bulgarians, on the one hand, and the Serbs and Greeks on the other. Bulgaria would not hear of conceding to these peoples the extensions of territory which they claimed in Macedonia. It was not till March 1912, when the Russophil Gueshoff-Daneff Cabinet came into power in Sofia, that the Serbo-Bulgarian treaty was concluded, which was indeed aimed in the first place against Turkey, but also had the Habsburg Monarchy in view. Two military conventions (of May 12 and July 12 1912) further developed this Serbo-Bulgarian alliance. Bulgaria now undertook, in case Austria-Hungary occupied the Sanjak of Novibazar, to contribute 250,000 men towards a war with this Power. On May 29 Ferdinand of Bulgaria concluded a treaty with Greece against Turkey. But at the same time he handed in peaceful declarations at Vienna, Berlin and Constantinople, and let himself be fêted in Vienna as a friend of the Habsburg Monarchy.

Balkan War.

At the beginning of July 1912 the Tsar Nicholas II., at his meeting with the German Emperor at Baltiski Port (Port Baltic), in Esthonia, laid stress upon his pacific intentions. But as early as Aug. there began the long-prepared conflict of the Christian peoples of the Balkans with Turkey, leading to bloody local struggles, in which there was no lack of atrocities on either side. In vain did the Central Powers endeavour to bring about an intervention of the Great Powers of Europe. On Sept. 30 1912 the order for mobilization was issued in Sofia, Belgrade and Athens. In order to have her hands free in this direction, Turkey thereupon determined to bring to an end the war against Italy by sacrificing Tripoli and Cyrenaica, and on Oct. 18 1912 the treaty of peace was signed at Lausanne. In the meantime the Balkan States had completed the last preparations for war. On Oct. 8 Montenegro declared war on Turkey, and soon after, on Oct. 17 and 18, Serbia, Bulgaria and Greece did likewise. To the astonishment of the European Great Powers they gained decisive victories over their opponent from the outset. The battle of Kirk Kilisse (Oct. 22) went in favour of the Bulgars, that of Kumanovo (Oct. 26) in favour of the Serbs. The Turkish troops, falling back rapidly, did indeed defend themselves successfully on the Chatalja lines against the oncoming Bulgarians, and thereby saved their threatened capital. But since none of the Great Powers would take active measures in their favour, they could not hope to reconquer the lost provinces. On Dec. 3 1912 an armistice was concluded between Turkey and Serbia, and between Turkey and Bulgaria. Greece took no part in it, but continued the struggle.

Berchtold's Balkan Policy.

The success of the Balkan States against Turkey meant a marked weakening of the prestige of Austria-Hungary in the Balkans. The entry of the Greeks into Salonika (Nov. 8 1912) and the advance of the Serbian troops to the Adriatic produced a particularly painful impression in Vienna. But consideration for the Slav peoples of the monarchy, who hailed with joy the victory of the Christian states of the Balkans over Turkey, and the dread of

incurring the open enmity of Russia by an energetic intervention on behalf of the Sultan, held the Vienna Government back and disposed it, as early as the end of Oct. 1912, to modify its demands. Albania was to be allowed to develop freely; Serbian aspirations towards the Adriatic were to be rejected, and Rumania's claims to an extension of territory to be considered. Berchtold demanded no more than security for Austro-Hungarian economic interests in the Balkans. On this account he refused in the most decided terms to consent to the proposal of the French Government that Austria-Hungary, like all the other Great Powers, should express her *désintéressement* in the events taking place in the Balkan peninsula.

Renewal of the Triple Alliance.

In so far as his plans concerned Albania and Serbia, Berchtold found Italian politicians in favour of them, since they saw in the spread of the Slav peoples to the Adriatic a danger to Italy, to oppose which in good time seemed to them more important than any further check to the influence of the Habsburg Monarchy, divided as this was against itself. The common danger brought about a *rapprochement* between the two Cabinets, which was considerably strengthened by Italy's annoyance at the attitude of France at the time of the Libyan War. Thus it happened that as far back as Dec. 5 1912, in spite of violent opposition on the part of the nationalist deputies, of the more important section of the press, and of Italian public opinion, the Triple Alliance was renewed once more for another six to twelve years, the period being reckoned from 1914 onwards.

Serbia and Russia.

But the moderation displayed by Austria-Hungary in her Balkan policy did not produce the effect which had been hoped for at the Ballplatz. It weakened rather her credit in the Balkans, disappointed the few partisans she had there, and encouraged the hopes of her many opponents. Paying no attention to Berchtold's declarations, the Serbs continued their efforts to extend their power to the Adriatic. On Nov. 10 1912 Serbian troops reached Alessio. At the same time Serbian politicians laboured to incite the other Balkan peoples against Austria-Hungary, since it was only at her expense they could hope to find compensation for the concessions which they had made in the March treaty with Bulgaria. In St. Petersburg, too, they left no stone unturned to create opinion against Austria-Hungary. And, in fact, in Nov. 1912 the Russian Cabinet declared itself in favour of the cession of an Adriatic port to Serbia, and was supported in this by France and England. The Russian trial mobilization increased the danger of a bloody collision. The Vienna Government on its side proceeded to prepare for war. The fact that Conrad von Hötzendorff was again entrusted with the position of chief of the general staff, which he had had to give up a year before because he had spoken in favour of an active military policy, showed that the war party had increased its influence at the Court of Vienna.

But the disinclination of the three emperors to conjure up a world war for the sake of Albania or Serbia, together with the influence of Great Britain, proved stronger than the urgency of the war parties either in Vienna or St. Petersburg. In opposition to Austria-Hungary, Bethmann Hollweg, the German imperial chancellor, and Kiderlen-Wächter, the German foreign minister, energetically upheld the point of view that a compromise with Russia was both desirable and possible. And in a like sense William II., when the Archduke Francis Ferdinand tried to convince him at Springe (Nov. 23 1912) of the necessity of an energetic course of action against the demands of the Serbs, insisted that, while he was in favour of using firm language, he was anxious to see all steps avoided which might lead to a rupture with Russia. In order that no doubt should arise as to the policy of the German Empire, Bethmann Hollweg, in announcing in the German Reichstag (at the beginning of Dec. 1912) the successful renewal of the Triple Alliance, added the remark that Germany must leave it to her Austrian ally to realize her aspirations alone, and would only join in a conflict in the case of a war of aggression against her, for the preservation of her own position in Europe and the defence of its own future and security.

Conferences in London.

Under the impression of these declarations Berchtold at the end of 1912 rejected Conrad's propositions, which aimed at the occupation of the Sanjak of Novibazar and ridding Albania of Serbian troops, and he sought rather to serve the interests of the monarchy by diplomacy. In this connexion it stood him in good stead that a change had meanwhile come over affairs at the Court of St. Petersburg, not uninfluenced by external factors, and especially by England. The peace party had gained the upper hand. As late as Nov. 1912 the Russian Government made a communication at Belgrade to the effect that it would offer no active opposition to the formation of an autonomous Albania, and requesting an attitude of reserve towards Austria-Hungary on the part of the Serbian Cabinet. Shortly afterwards, on the suggestion of Sir Edward Grey, a conference of ambassadors in London was decided upon, to take place at the same time as the peace negotiations which were being carried on there between Turkey and her opponents, with a view to finding a solution of the outstanding questions at issue between Russia and Austria-Hungary. After long hesitation Berchtold, under pressure from Germany and Italy, consented to the conference of ambassadors, but insisted that as a matter of principle Austria-Hungary should take no part in any discussion of the question as to whether Serbia should be permanently established on the Adriatic. Serbia thereupon declared her willingness to yield to the decision of the Great Powers. Yet the Austro-Hungarian and Russian troops remained under arms, and Serbian intrigues still went on. The negotiations of the London conference of ambassadors proceeded slowly. When the peace conference, which was sitting at the same time, came temporarily to an end on Jan. 7 1913, owing to Turkey's refusal of the demand of the Balkan States that she should cede the three fortresses of Adrianople, Scutari and Janina, which had not yet fallen, the conference of ambassadors presided over by Sir Edward Grey made efforts to prevent a resumption of hostilities; but these attempts were unsuccessful. On Feb. 3 1913 began the second Balkan War.

Austro-Russian War Averted.

Meanwhile the deliberations dragged on in London as to the frontier of the new Albanian state which was to be set up. Russia in this matter presented the views of Serbia and Montenegro, but met with resolute opposition not only from the representatives of Austria-Hungary but also from those of Italy. And it looked at last as if it would come to an armed conflict between Austria-Hungary and Russia. But at the last moment the danger was averted. Prince Gottfried zu Hohenlohe was sent on a special mission to St. Petersburg and succeeded in convincing Nicholas II. of Francis Joseph's pacific intentions. The negotiations now opened led in March to the cancelling of the mobilization on the frontiers which had been set on foot by both Powers. At the same time the Russian representative at the London conference of ambassadors announced his sovereign's readiness to consent to the allotment of Scutari to Albania in the event of Austria-Hungary's acceding to the separation of Diakova, Ipek (Peć) and Prisren from Albania. On March 20 the representative of Austria-Hungary handed in a declaration in the same sense.

Second Balkan War.

By now the war between the Balkan States and Turkey had taken its course, leading, in spite of the unexpectedly gallant defence of the Turks, to the fall of Janina (March 6) and Adrianople (March 26). On account of the wrangling which broke out between Bulgaria on the one hand, and Serbia and Greece on the other, as to the partition of Macedonia, on April 16 1913 Ferdinand of Bulgaria concluded an armistice with Turkey. But there was no sign of the peace which was desired on all sides. Serbia, in defiance of the protests of the Vienna Cabinet, continued to occupy Northern Albania with Durazzo, and Montenegro continued to besiege Scutari, although the London conference of ambassadors had assigned it to the Albanian state; and the Great Powers decided on a naval demonstration against Montenegro, which was not, however, intended seriously by all the participants. The war party at Vienna, led by Conrad, wished to force the Montenegrins to raise the siege, if necessary by arms,

but did not win their point. On April 23 Scutari fell into the hands of the Montenegrins. It was not till then that Berchtold nerved himself to the declaration that the Habsburg Monarchy would not tolerate such an insult, and made the necessary preparations for armed intervention. Montenegro thereupon submitted to the dictates of the Great Powers. On May 5 the Montenegrin troops evacuated Scutari and on the next day the Serbs left Durazzo. At the end of May peace preliminaries were concluded between the Turks and their opponents. But it was impossible to arrive at an agreement between the victors as to the division of the territory which had fallen to them.

Austria-Hungary and Rumania.

Notwithstanding the fact that it had had its way so far as Albania was concerned, the prestige of the Vienna Government in the Balkans had seriously diminished in the course of the two wars, not only in the eyes of the victorious peoples, whose self-confidence had mightily increased, but also in the eyes of its Balkan ally Rumania. King Charles had wanted to join in from the beginning of the first Balkan War, in order to prevent a hegemony of Bulgaria in the Balkans, and had only allowed himself to be persuaded to renew for the fifth time his alliance with the Powers of the Triple Alliance by an engagement from the Central Powers that they would see to it that Rumania received a corresponding extension of territory in the S.E. (Silistria and the surrounding territory was what they had in view). He now strongly pressed the Court of Vienna for the fulfilment of this engagement. Berchtold did in fact make every effort to decide the Bulgarian Government in favour of suitable concessions to Rumania. But when his efforts broke down, those circles in Bucharest which favoured the Triple Entente (France, Russia, England) managed to make King Charles acquiesce in invoking Russia's mediation in order to acquire the desired increase of territory. But Russia's success at Sofia did not satisfy the Rumanians, and induced them to join hands with Ferdinand of Bulgaria's enemies. This was an advantage for Austria-Hungary, which was, however, set off by the increasing influence of the Entente Powers and their party in Rumania.

Strained Relations with Italy.

Austria-Hungary's leading statesmen met with no better success in their efforts to establish permanently friendly relations with Italy. San Giuliano's desire for common action with the Habsburg Monarchy in the Adriatic question had indeed led recently to a *rapprochement* between the two Cabinets. In the course of 1913 German statesmen had also succeeded in persuading Italy to further military commitments and to the conclusion of a naval convention, the object of which was defined as "the attainment of naval supremacy in the Mediterranean by the defeat of the enemy fleets" in a war against the Western Powers. But the voice of the Italian press and of nationalist circles, who demanded more and more insistently the dissolution of the Triple Alliance and union with the Triple Entente, did not leave the Central Powers any confidence in Italy's loyalty to her engagements. Meanwhile the third Balkan War had broken out. Serbia and Greece, joined by Rumania and Turkey, advanced against Bulgaria. The latter, left in the lurch by Russia and only supported diplomatically by Austria-Hungary, succumbed, and by the Peace of Bucharest (Aug. 10 1913) Bulgaria found herself compelled to enter into an agreement with her enemies by which she was a serious loser.

Effect of the Balkan Wars.

The outcome of these three wars meant for the Austro-Hungarian Monarchy a notable loss of prestige in the Balkan peninsula. Her adversaries in this quarter, Serbia and Montenegro, and especially the former, had achieved a considerable extension of their possessions, and henceforth, being no longer separated by the Sanjak of Novibazar, were in a position to join forces against the Habsburg Monarchy when the right moment came. The Bulgarians, however, disappointed in their hopes, ascribed the humiliating defeat which they had suffered in the third Balkan War to the feeble attitude of the Vienna Cabinet, which had indeed taken the first steps in the direction of active participation in the war in favour of Bulgaria, but had then, out of fear of Russia and under German and Italian pressure, contented itself with a fruitless diplomatic intervention. The fact that Berchtold's efforts to obtain a revision of the Peace of Bucharest in favour of Bulgaria met with no result could not contribute towards strengthening Austria-Hungary's credit at Sofia. On the other hand, the line of action of the Vienna Government, which in its own interest was working incessantly for a compromise between Bulgaria and Rumania, but could satisfy neither of these two Powers, led to a clearly perceptible estrangement between the Courts of Vienna and Bucharest, which enabled the Rumanian friends of the Triple Entente to win from the King his acquiescence in paving the way to better relations with the Western Powers and Russia. The only advantage which balanced these heavy losses of power and prestige for Austria-Hungary was the dissolution of the Balkan League, the revival of which was prevented by the inextinguishable hatred between Serbs and Bulgarians, a fact of all the greater importance for the Vienna Government as its relations with Serbia became more and more strained and the probability of an armed conflict increased.

Resistance of Serbia.

The London conference of ambassadors had, on July 29 1913, come to an agreement as to a fundamental law for Albania, and at its final sitting on Aug. 11 had settled the southern frontier of Albania, long a subject of controversy. Serbia alone declined to give up the Albanian territories which she had already occupied in defiance of the London decrees, and persisted in her resistance when the Vienna Government pressed for their evacuation. The growing differences between the Triple Alliance and the Triple Entente meant that no united action could be expected from the European Great Powers. Italy and Germany—the latter more on grounds of prestige, the former because her interests in this case ran parallel with those of Austria-Hungary—associated themselves with the Vienna Government when, on Oct. 15 1913, it again insisted at Belgrade on the execution of the London decrees. Serbia at first again refused; but when Berchtold showed that he was in earnest and on Oct. 19 demanded at Belgrade, under threat of force, the evacuation of the Albanian territory occupied by Serbia, the Serbians submitted to the dictates of the Vienna Government (Oct. 20 1913) in accordance with advice from the Triple Entente. The Serbian press, however, continued to create prejudice against the policy of the Ballplatz, and the Serbian Government used every opportunity of encouraging movements which had as their object the winning over of the Southern Slavs living under the Government of the Habsburg Monarchy to the idea of a Greater Serbia.

Doubtful Attitude of Rumania.

In Rumania, too, the agitation against Austria-Hungary made headway every month. The agitation in Bucharest in favour of the Hungarian Rumanians became more and more active, and their liberation from the domination of the Magyars was indicated as a desirable and possible object of Rumanian policy. In order to achieve it a *rapprochement* was advocated between Rumania and Russia, and a suitable pretext was found in Nicholas II.'s very cordially expressed congratulations on King Charles's successes in the last Balkan War. It is true that the visit of the Rumanian heir to St. Petersburg (March 27 1914) did not bring about that open passing-over of Rumania into the camp of the Triple Entente which Russia had hoped for. King Charles could not be brought to this point, and the Rumanian Government, too, did not at that moment want to break definitely with the Central Powers. But the speeches accompanying the exchange of toasts at the meeting of Nicholas II. with Charles at Constantza on June 14 1914 left no possible doubt that the friends of the Triple Entente had gained the upper hand at Bucharest. As early as this, Count Ottokar Czernin, the representative of Austria-Hungary at Bucharest, expressed the decided opinion that, in the event of a war between the Central Powers and the Triple Entente, King Charles would not fulfil his pledges. At the same time he uttered a warning against underrating the danger of an encirclement of the Dual Monarchy through the formation of a new Balkan League under the patronage of Russia and France.

To hinder this encirclement now became the principal endeavour of Viennese statesmen, who were untiringly at work trying to compose the outstanding differences between Bulgaria on the one hand and Turkey and Rumania on the other, and if possible also to win over Greece to a closer adhesion to the Central Powers. But all their efforts broke down owing to the divergent interests and the mutual distrust of the Balkan States, which came clearly to view during the negotiations conducted under the mediation of the Central Powers during the winter of 1913–4. The Turko-Bulgarian Treaty, which was nearly concluded in May 1914, did not come to anything; still less did the compromise between Rumania and Bulgaria, which had been furthered with such especial zeal on the part of Vienna. And the *rapprochement* of Greece with the Triple Alliance, desired by Emperor William, could not be realized, since the claims of the Greeks met with insuperable opposition both in Sofia and in Constantinople.

Balkan Policy of Austria-Hungary.

Not the least of the factors contributing to these unsatisfactory results was the difference of opinion in influential circles in Vienna and Berlin as to the value of the various Balkan States in case of an international conflict. Emperor William was a resolute opponent of King Ferdinand of Bulgaria, whom he did not trust; on the other hand, he was firmly convinced that in case of war Charles of Rumania would be true to his engagements as an ally. On this account he endeavoured to persuade the Vienna Government to bring Rumania over entirely into the camp of the Triple Alliance, even at the cost of sacrifices and of the danger that Bulgaria might join the opponents of the Central Powers. But Berchtold was afraid that the Bulgarians, left in the lurch by Austria-Hungary, might come to terms with Serbia, Greece and Rumania, and in company with them and with Russia fall upon the Habsburg Monarchy. Hence he held fast to his policy, which saw in the maintenance and exacerbation of the differences existing between Bulgaria and the other Balkan States the only means of preventing the formation of an alliance of all the Balkan peoples against the monarchy. The conflicting points of view of leading statesmen in Vienna and Berlin led to very lively debates, and threatened seriously to impair the good understanding between the two Governments. However, Berchtold gradually succeeded in bringing round the Emperor William and the German statesmen to his views. From March 1914 onwards it was determined that the union of Bulgaria with the Central Powers must remain the main object of their policy, and that agreements with the rest of the Balkan States must only be entered into in so far as they should not be in conflict with the just desires of Bulgaria.

Disagreement between Vienna and Berlin.

The removal of this discord was hailed with all the more joy by the Vienna Cabinet since its relations with Italy were getting more and more strained. San Giuliano, it is true, maintained a correct demeanour towards the Vienna Government and worked for a compromise in the ever-recurring conflicts to which the divergent interests of the two states in the Balkans gave rise. It was even possible, in the discussions which took place between him and Berchtold at Abbazia in April 1914, to arrive at an agreement as to the policy of Austria-Hungary and Italy in the Balkan question, based upon the maintenance of the autonomy of the Albanian state, which had been set up in the meantime and for the government of which Prince William of Wied had been designated. But the attitude of the press and of the deputies with nationalist sympathies, not to speak of the Italian representatives in Albania, made it apparent that influential circles beyond the Alps were endeavouring to frustrate San Giuliano's policy.

Tension with Italy.

In the eyes of leading Viennese statesmen the sympathy for the Triple Entente which was displayed by the Italians with ever-increasing frankness was all the more ominous since they saw that France, Russia and England were taking steps to increase their own military strength, and also had information of the negotiations which were being conducted by all three Governments with those of Spain, Italy and the Balkan States, which were believed to have as their object the isolation of the Central Powers. At that time, however, the outbreak of a world war was not held to be imminent in Vienna, for it was known that negotiations were going on between Berlin and London aiming at the establishment of better relations. Count Mensdorff, the Austro-Hungarian ambassador at the Court of St. James, did his utmost to further these efforts. But conditions in the Balkans pressed for a decision. In Vienna it was believed that France and Russia had been successful in their efforts to bring into existence a Balkan League which should also include Turkey, and which would have threatened the existence of the monarchy.

The "Encirclement" Danger.

On June 22 1914, before the assassination of the heir to the throne of Austria-Hungary, Conrad von Hötzendorff, as chief of the general staff, drew up a memorandum in which he described the existing conditions in the Balkans as intolerable, and insisted on the necessity for using clear language at Bucharest. The Rumanian Government must be forced, he said, to declare openly whether it would make common cause with the Central Powers or not. In the latter case an attempt must be made to decide Bulgaria, by far-reaching promises, to bring to a conclusion the negotiations for an alliance which had been going on for a considerable time. These views of Conrad's were shared not only in military circles but also by Austrian statesmen of authority. In a memorandum intended for the German Government, which was also drawn up before the murder of Francis Ferdinand, Count Berchtold[1] emphasized the urgency of making every effort to form a Balkan League, under the leadership of the Central Powers, which should include Bulgaria, Rumania, Greece and Turkey, and have as its objective the suppression of Serbia as a political power in the Balkans.

Austria for Strong Measures.

Before this document was dispatched to Berlin the news arrived in Vienna that Francis Ferdinand, with his consort, Sophie, Duchess of Hohenberg, *née* Countess Chotek, had been murdered in Sarajevo. It confirmed the already settled conviction in this quarter of the necessity for coming to a reckoning with Serbia. On July 5 the Vienna *mémoire* was handed to the German Emperor by Councillor of Legation Count Alexander Hoyos (b. 1876), who had been sent on a special mission to Berlin, in the presence of the Austro-Hungarian ambassador, Count Ladislaus Szögyeny-Marich (1841–1916), and on the following day to the imperial chancellor, Bethmann Hollweg. Authoritative circles in Berlin adopted the views of the Vienna Government, and gave it to understand that it might reckon on Germany's aid even in case international differences were to arise from the Austro-Serbian conflict.

Berlin Agreement.

It was in reliance upon these promises, which were repeated in the most emphatic way by the German ambassador at the Court of Vienna, Tschirsky-Bögendorff, that Berchtold, at the sitting of the council of ministers on July 7 1914, gave utterance to the opinion that they would be forced at last to a military reckoning with Serbia. His point of view met with general agreement; nevertheless Count Stephen Tisza, the Hungarian prime minister, who had already on July 1st expressed his dissent and the reasons for it in a memorandum presented to Emperor Francis Joseph, desired not only the opening of diplomatic negotiations but also the formulating of demands possible of fulfilment. His first point he carried, but in the second he failed. The council of ministers decided to adopt the course of diplomatic negotiations, but at the same time to lay down conditions the rejection of which would be inevitable. In that case the Serbian question would have to be solved by the power of the sword. Tisza, ill content with this conclusion, reiterated his dissentient

Ultimatum to Serbia.

[1] The basis of this document is to be found in a *mémoire* drawn up by the envoy extraordinary and minister plenipotentiary, Baron Ludwig Flotow (b. 1867). It was later amplified by Rudolf Pogatscher (b. 1859), who occupied the same position and was particularly well informed as to the Balkan question. From the middle of June onwards it was revised by Baron Franz Matscheko (b. 1876), of the Austro-Hungarian Foreign Office, and finally by Count Berchtold.

views in a second memorandum of July 8 and counselled moderation, laying stress on the danger of international complications. This view should have been reënforced by the report drawn up by Friedrich von Wiesner (b. 1871), who had been sent by the Vienna Ballplatz to Sarajevo, on the circumstances in which the murderous attack on the heir to the throne had taken place. This report established the fact that no direct connexion could be proved between the murderer and the Serbian Government. But this report failed of its effect. Authoritative circles in Vienna remained under the conviction that the Court and Government of Belgrade had for long lent their benevolent support to the Greater Serbian movement, and held to their determination of putting an end to an unbearable situation. The dangers which might arise from drastic measures were indeed weighed; the possibility of a world war was even considered. But the opinion predominated that all must be staked on one card. "Better an end by fear than fear without end," ("*Lieber ein Ende mit Schrecken, als ein Schrecken ohne Ende*") was the *mot* of a leading statesman. These circles were confirmed in their resolve to appeal to arms by the pronouncements of Conrad von Hötzendorff, who, in reply to a question, summed up his judgment in the following sense: that the military prospects of the Central Powers in a world war (Great Britain's intervention on the side of the enemy not being yet reckoned with seriously) were no longer so favourable as in previous years, but were certainly more favourable than they would be in the near future. That decided it. On July 14 the decision was adopted of sending Serbia an ultimatum with a short time-limit. Tisza, after long vacillation, acquiesced, but with the condition that Austria-Hungary was to make a solemn declaration that—with the exception of necessary minor rectifications of the frontier—she sought no territorial gains at the expense of Serbia. By this means Tisza hoped to placate Russia and to deprive the Italians of any pretext for advancing any claim to compensations under Article VII. of the Treaty of the Triple Alliance. This request of Tisza's was indeed taken into account at the conference of ministers of July 19, but on the same occasion Berchtold declared that Serbia was to be made smaller and the provinces taken from her were to be divided among some of the other Balkan States.

The note to Serbia, which had not found its final form till after repeated modification of its language,[1] was read out, and the time for its presentation to the Serbian Government appointed for the afternoon of July 23.

Its essential points ran as follows:—Since the Greater Serbian movement directed against Austria-Hungary has been proceeded with in recent years with the ultimate object of separating from the Habsburg Monarchy certain of its parts; and since the Serbian Government, in contradiction with the declarations handed in by it on March 31 1909, has not only done nothing towards its suppression, but has rather encouraged it, the Austro-Hungarian Government must formulate certain demands in order to put an end to this state of affairs. In these demands are included, amongst others, the condemnation of agitation having as its object the breaking away of portions of the monarchy and the admonition of the peoples against a continuance of this course: both to be accomplished through an announcement in the official press organ and through an army order on the part of the king; the suppression of the Greater Serbian agitation on Serbian soil; the dissolution of societies working for this object; the dismissal of the officials and teachers compromised; the participation of representatives of the Imperial and Royal Government in the measures which the Serbian Government should be under the obligation to undertake with a view to the suppression of the Greater Serbian movement.

The presentation of the note took place at the appointed time; on July 24 the world was informed of its contents. Only Germany approved unreservedly the *démarche* of the Vienna Government; the remaining Powers raised objections. Sazonov, the Russian foreign minister, broke into a violent outburst against Austria-Hungary, and declared it to be a matter of international concern. Sir E. Grey described the note as "the most formidable document" that one State had ever addressed to another. Negotiations began at once between the groups of Powers. They aimed at the extension of the time-limit of 48 hours which had been allowed to the Serbs. England and Russia were especially active in this sense. But Austria-Hungary refused any prolongation of the time-limit. On July 25, shortly before the expiry of the appointed interval, the Serbs handed in their answer. They declared themselves ready to comply with the majority of the demands of the Vienna Government, but with regard to certain points—for instance, where it was a question of the participation of the Austro-Hungarian representatives in the judicial enquiry to be held in the territory of the kingdom of Serbia, and of the dismissal of the officers and officials who were compromised—certain reservations were made; at the same time the Serbs emphasized their willingness to endeavour to reach a friendly solution of the conflict by referring the decision to the Hague Court of Arbitration, or to those Great Powers who had collaborated in the composition of the Serbian declaration of March 31 1909. But the Austro-Hungarian minister declared Serbia's answer to be unsatisfactory, and diplomatic relations were broken off between Vienna and Belgrade.

Efforts to Avert War.

The Vienna Cabinet's harsh attitude nowhere met with approbation; the German Government itself did not approve it. The Emperor William indeed was of opinion that Austria-Hungary had gained a great moral victory, and that no cause of war remained. But neither his efforts, nor those of Sir Edward Grey, which were directed towards the mediation of the Great Powers not directly involved, met with success. On July 28 Austria-Hungary declared war on Serbia. The Great Powers now strove to localize the conflict. But all their attempts came to naught. Even the English proposal for direct negotiations with a view to an understanding between the Cabinets of Vienna and St. Petersburg led to no result. On the evening of July 29 the order was given for mobilization in the military area on the S.W. front of Russia situated on the border of Austria-Hungary. On July 31 the Russian order for a general mobilization was issued, and answered by similar measures on the part of Austria-Hungary and Germany. On Aug. 2 Germany declared war on Russia, and the day after on France; on Aug. 4 England and Belgium on Germany; on the 6th Austria-Hungary on Russia; other Powers followed suit. The World War, so long dreaded by the Great Powers of Europe, had broken out.

The World War.

Attitude of Italy.

The Central Powers had now to make sure of the aid of their allies and to win new combatants to their side. But the efforts which they made towards this end brought them disappointment upon disappointment. The conversations which had taken place with Italy in July 1914 had made them realize that they could not reckon on an immediate participation of the Italian troops on the side of the Triple Alliance. As early as July 25, moreover, San Giuliano had announced that he would open the question of compensation for Italy in case of an Austro-Serbian war. This announcement he repeated after the declaration of war, but made it clear at the same time that Austria-Hungary was not to expect active support from the Italians, since she had taken the offensive against Serbia. Under pressure from the German Government, which still cherished the hope of deciding Italy, by far-reaching concessions, to take part in a world war on the side of the Central Powers, Berchtold declared himself ready in principle to recognize the Italian claims to compensation for every annexation made by Austria-Hungary in the Balkans, but in any case only on the assumption that Italy would observe a friendly attitude towards the Habsburg Monarchy in an Austro-Serbian war, and in case of a world war fulfil her obligations as a member of the Triple Alliance. But as early as Aug. 1 San Giuliano insisted that the *casus foederis* had not arisen for Italy in the case of the Russians also; for the time being she would remain neutral; but coöperation with her allies at a later time was referred to as not excluded. It was in the same sense, though in the most cordial terms possible, that Victor

[1] A prominent part in the drafting of the ultimatum was played by Count Johann Forgach (b. 1870) and Baron Alexander Musulin (b. 1866), who had also, as Berchtold's advisers, a decisive influence on the course of events generally at this time.

Emmanuel answered the telegram in which Francis Joseph expressed his expectation of seeing the Italian troops fighting side by side with those of the Habsburg Monarchy.

Still less gratifying to Vienna were the reports which came in at the same time from Bucharest. The hopes which the Emperor William had built on King Charles's faithfulness to his treaty obligations were not realized. The Rumanian ruler evaded a decisive pronouncement as to his attitude in a world war; and Bratianu, the minister-president, did likewise. Czernin, the Austro-Hungarian minister at Bucharest, maintained that at first nothing but neutrality could he reckoned on on the part of Rumania, and insisted that the attitude of the Bulgarians and Turks, together with the course taken by the events of the war, would be decisive for any further action of the King and Government. It was significant that Bratianu spoke of the necessity of maintaining a balance in the Balkans, and at the same time pointed out the difficulties which would confront the King and the Government in consequence of the hostile attitude of influential Rumanian circles to the Magyars. It was in vain that Francis Joseph and William II. used their personal influence to try and persuade King Charles to take action in the sense they wished. No effect was produced even by the promise made by them to the King on Aug. 2 1914 that they would help Rumania to obtain possession of Bessarabia, after the war had come to a successful end, if she would join in the struggle on the side of the Triple Alliance Powers. The crown council held on Aug. 4 decided that Rumania could not admit that the *casus foederis* had arisen. The assurance given hy Charles at the same time, that he would safeguard the Rumanian frontiers and apprise Bulgaria that she would have nothing to fear from Rumania if she ranged herself with the Central Powers, could be of no greater comfort to his disillusioned allies than his solemn declaration that he would never consent to Rumania taking the field against Austria-Hungary.

Attitude of Rumania.

The Central Powers were rather more fortunate in their quest for new allies than in their attempts to persuade Italy and Rumania to fulfil their engagements. On Aug. 1 1914 the representatives of Germany and Turkey had signed a treaty by which they hound themselves to remain neutral in the conflict between Austria-Hungary and Serbia; but the *casus foederis* would arise at the moment when Russia entered the war. In this event Germany promised Turkey military support, and guaranteed her existing territorial position as against the Russians. By identical notes of Aug. 1 1914 Austria-Hungary adhered to this treaty, which was to last till the end of 1918. But for the time heing the Turks did not actively intervene, for their army was not yet properly equipped, and the influence of the friends of the Entente at Constantinople was still too strong. In order to strengthen the Government, which was friendly to the Central Powers, and to make it possible for them shortly to take an active part against the Entente, Germany promised them, as early as the first weeks of Aug. 1914, though only verbally, that in the event of a complete victory of Germany and her allies, their wishes should be furthered both in the matter of the abolition of the Capitulations and of final settlement with Bulgaria; that all Turkish provinces which might be occupied by the common enemy in the course of the war should be evacuated; a series of rectifications of the frontier to her advantage would be made, and they would receive a proportionate share in the war indemnity which was to be expected. Direct [illegible] from the Turks were met by Berchtold with the [illegible] promises in the name of Austria-Hungary.

Alliance with Turkey.

On the other hand, the efforts of the Central Powers to decide Bulgaria to an alliance broke down. At first, indeed, it looked as if the negotiations which had already been conducted by Austria-Hungary at Sofia for a long time in this sense would speedily lead to a profitable result. Austria-Hungary showed herself inclined, in return for Bulgaria's adhesion to the Triple Alliance, to guarantee her existing territorial possessions, and, in the event of a favourable outcome of the impending conflicts, to gratify Ferdinand's aspirations towards the acquisition of "ethnico-historical boundaries" against states which had not joined the Triple Alliance. By the early days of Aug. 1914 the negotiations had advanced so far that the signature of the treaties with Germany and Austria-Hungary seemed imminent. Berchtold and Bethmann Hollweg pressed for a decision, the latter more especially on the ground that he still hoped to win over Rumania definitely to the side of the Central Powers. If this could be achieved, then Bulgarla, assured against attacks from the Rumanian side, might be prompted to draw the sword against Serbia, and the majority of the Austro-Hungarian troops which were marching against Serbia could be diverted against Russia. But Ferdinand of Bulgaria refused to embark on a war against Serhia. He laid stress on the dangers which threatened his kingdom in such a case from Greece, Rumania and Turkey; he also alluded to the large offers which had been made him by Russia, and held that he could only come to a decision after his relations with Rumania and Turkey had been cleared up and the negotiations for a treaty with these Powers had heen concluded. It was clear that Ferdinand of Bulgaria, too, did not wish to enter the war before the preponderance of the Central Powers over their opponents could be assumed with greater confidence. But successes in the field remained to seek in the Eastern theatre of war. After promising beginnings, the campaign of the Austro-Hungarian armies took an unsuccessful turn, and decided Ferdinand to be prudent. He declared that he would remain neutral, hut for the present he could do no more.

Negotiations with Bulgaria.

But the ill success of the Austro-Hungarian armies did not produce an effect on the Bulgarian Government only. With the advance of the Russians and their approach to the Rumanian frontiers, the influence of the friends of the Entente at Bucharest increased. The news arriving at Berlin and Vienna at this time caused the worst to he feared. It was believed that an overthrow of the dynasty was imminent, together with an immediate alliance of Rumania with the enemy, and an advance of Rumanian troops into Transylvania. The most pressing advice reached Vienna from Berlin in favour of far-reaching concessions, even of a territorial nature. But, strongly influenced by Tisza, Berchtold refused any concessions in this direction. Under the advice of King Charles, who was already seriously ill, and was torn by a terrible conflict between personal honour and the wishes of his people, the Central Powers sought to work upon public opinion in Bucharest by a declaration that the defection of Rumania would be met by an immediate advance of troops into the country. But their threats remained ineffectual, for it was known in Bucharest that the troops necessary for such an enterprise were not forthcoming. In reality Germany was counselling Vienna not to oppose the march of Rumanian troops into Transylvania by force of arms, since for the moment a defence of the frontiers was impossible; but rather to tolerate the advance, and to announce that it had taken place in order to defend the territory from occupation by Russian troops. Berchtold refused, and Tisza, whose acrimony over the German proposals know no bounds, declared that he would rather see the Russians than the Rumanians in Transylvania. Meanwhile the tide of warlike enthusiasm at Bucharest mounted higher and higher. The Government entered into a written agreement with Italy providing for common action on the part of both of them. A crown council was summoned for the early days of Oct., which was to come to a decision against the Central Powers. Only at the last moment was it possible to avert the danger. The crown council was cancelled, and Rumania for the time being remained neutral. A few days later, on Oct. 10 1914, King Charles of Rumania died. He had not fulfilled the engagements into which he had entered, but he had at least successfully prevented his troops from fighting against the Central Powers.

Central Powers and Rumania.

One of the chief reasons which had delayed the Rumanians in going over to the camp of the Entente was the fear enter-

tained by leading Rumanian politicians that so soon as her troops had crossed the Hungarian frontier Bulgaria and Turkey would attack Rumania. The negotiations carried on through the intermediary of Austria-Hungary between the Courts of Sofia and Bucharest had then, it is true, been proceeded with, but had broken down again, this time owing to the reciprocal distrust and the irreconcilable interests of the two Powers. At the same time it had become known to those in Bucharest how closely the Turks had attached themselves to the Central Powers, and that they were holding themselves in readiness to enter the World War on their side. Rumania consequently declared that she could no longer leave Bulgaria a free hand against Serbia. Thus under the new King of Rumania, Ferdinand, who was not bound by ties of personal friendship with the sovereigns of Austria-Hungary and Germany, the party hostile to the Central Powers gained in influence. Ferdinand did indeed stand firm in his neutrality, and he rejected Russia's summons to hasten to the aid of the Serbians, who had been attacked by Austria-Hungary. But Czernin could not succeed in obtaining from him a binding declaration that he would not let his troops enter the field against the Central Powers.

Negotiations with Bulgaria.

At this time Germany and Austria-Hungary were equally powerless to decide the King of Bulgaria to take part in the Serbian War. Even the increased inducements held out to him in this event by the Vienna Government did not move him from this attitude of reserve. This was due not only to his distrust of Rumania, Greece and Turkey and his fear of Russia, but also to his doubt as to whether by joining the Central Powers he would really be placing himself on the winning side. Accordingly he was forever changing his attitude and that of his Government according to the vicissitudes of the war. If the armies of the Central Powers met with success, they all showed a growing inclination to bring the treaty negotiations, which had never been allowed to drop for a minute, to a conclusion. But if, as in Dec. 1914, unfavourable news reached Sofia as to the military situation of the Central Powers, then the old reasons for dragging on the negotiations were raked up again. The fact that the Entente Powers kept going further and further in their offers to Bulgaria, should she enter the war on their side or even should she remain neutral, contributed towards strengthening the resolve of the Bulgarian Government to put the screw on the Central Powers in the matter of their demands. Thus at the end of 1914 they demanded far-reaching concessions in the matter of their territorial claims, and that under a written promise. Austria-Hungary was refractory for a time, but at the beginning of 1915 declared herself prepared even for these concessions, but demanded, with the backing of the German Government, the armed intervention of Bulgaria on the side of the Central Powers. But neither King Ferdinand of Bulgaria nor Radoslavov, the Bulgarian minister-president, was willing to concede this, for the military situation of the Central Powers was for the moment unfavourable. They declared their wish to remain neutral.

Negotiations with Italy.

The negotiations with Rumania and Bulgaria revealed the fact that both Powers, different though their interests might be, followed a similar policy. They wished to delay their decision as long as possible; they wished at the right moment to join the side of the winning party so as to carry off the greatest possible advantages at the price of the least possible sacrifices. In these circumstances the importance to the outcome of the war of Italy's decision increased every month. For a long time, until far on in the winter of 1914, the policy of leading Italian statesmen was dictated by the wish to preserve their neutrality while keeping up their armament. They accounted for their attitude by referring to the letter and the spirit of the Triple Alliance; they gave their former allies friendly words, but maintained a cordial attitude towards the Entente Powers. At the same time they urged at Vienna their demands for compensations by interpreting Article VII. of the Triple Alliance Treaty in their own favour. It was not at first clear what they meant by it. During the official negotiations which took place between the Cabinets of Vienna and Rome, no word was spoken on the Italian side of old Austrian territories. But it was learnt at the Ballplatz, by way of Berlin, that Italy was thinking of the Trentino. Berchtold absolutely refused to listen to any such demands. He would not hear of a territorial indemnification on any account, and was warmly supported in this by Tisza, while Conrad even at that time, or at any rate in times of military misfortune, considered that even Italian neutrality would not be too dearly bought at the price of great sacrifices. But neither the prayers of the leading military commander nor the unceasing efforts of leading German political and military circles were able to change Berchtold's mind. He went on, indeed, with the negotiations, but spun them out without binding himself to anything. When San Giuliano died on Oct. 16 1914, nothing decisive had yet happened. Even during the few weeks for which Salandra, the then Italian minister-president, directed Italy's foreign policy, no energetic steps were taken. Salandra fell in with the feeling of the country. It was not until Sonnino had taken over the leadership of Italy's foreign affairs that a further advance was ventured on by Italy in view of the unfavourable military position of the Central Powers, and under the influence of that section of the Italian press which was active in the interests of the Entente. It was once more reported in Vienna that Sonnino had spoken in Berlin of the cession of the Trentino, and that the German Government was now advocating this sacrifice. But even now Berchtold refused to entertain the question. Francis Joseph, so it was said, would never give his consent to a diminution of his empire. Only Sonnino kept on his way unperturbed. At the beginning of Dec. 1914—when Austria-Hungary was advancing upon Serbia—he had a declaration made at Vienna to the effect that the excited state of opinion in Italy compelled him to press for the adjustment of the question of compensations. Salandra supported him, by speaking in Parliament of Italy's *sacro egoismo*, her just aspirations and legitimate interests, and, while giving expression to the pacific character of the Italian Government, he stated emphatically that neutrality alone was not sufficient to assure Italy's interests in all circumstances until the end of the war.

In the middle of December the negotiations between Vienna and Rome began afresh, but at once came to a deadlock. The German Government, which attached extraordinary importance to winning over Italy, now tried to persuade the Ballplatz to make concessions. At the same time it sent to Rome Prince Bülow, who worked in the same sense, and represented concessions on the part of Austria-Hungary as a sacrifice, heavy indeed, but necessary in order to assure Italy's neutrality. But Berchtold was still resolutely opposed to such a demand, and expressed this view also in his direct negotiations with the Italian ambassador in Vienna, the Duke of Avarna.

Burian Succeeds Berchtold.

Berchtold's fall from power, and the appointment of Baron Burian to succeed him as Austro-Hungarian foreign minister (Jan. 13 1915), made but little change in the position of the Vienna Government. Negotiations with Italy were indeed continued, but led to no *rapprochement* between the two opposing points of view. It was not till March 9 1915 that Burian expressed his willingness to discuss with Italy, in principle, the cession of Austrian territory. He did so under the impression of the unfavourable military position of the Triple Alliance Powers—the Russians were fighting in the Carpathians, and Przemysl was about to fall—and with the knowledge of the renewal in Feb. 1915 of the agreement between Italy and Rumania, which let it be feared that a declaration of war by Italy would be followed by that of Rumania; under increasingly heavy pressure, moreover, from the German Government, which, in the event of a favourable outcome of the war, held before the eyes of the Vienna Government, as compensation for the losses of the monarchy in Tirol, not only a loan in cash but also the rich coal-mines of Sosnovka.

The opening of negotiations at once showed how far the Italian demands exceeded what Austria-Hungary was now pre-

pared to concede. Sonnino asked for wide territories and their immediate transfer to the Italians. Burian firmly refused the latter proposal, and only offered the greater part of Italian Southern Tirol, and even this on condition that Italy should preserve a benevolent neutrality towards the Central Powers until the end of the war and leave Austria-Hungary a free hand in the Balkans. Sonnino rejected Burian's offers as insufficient, and during the next few weeks increased his demands. On April 10, on Sonnino's instructions, a memorandum containing Italy's new conditions was handed in at Vienna. They made it clear that Italy was no longer striving to complete her national growth while preserving her former relations with the Habsburg Monarchy, but was aiming at the realization of her national unity and at the achievement of complete supremacy in the Adriatic. She demanded, among other things, the whole of S. Tirol, with the boundaries of the Italian kingdom of 1811, Gorizia and Gradisca, and the conversion of Trieste with its surrounding territory into a community independent of Austria-Hungary; the cession of a number of the most important islands in the Adriatic; the immediate occupation of these lands by the Italians; the recognition of the full sovereignty of Italy over Valona and its territory; and a declaration of Austria-Hungary's *désintéressement* as regards Albania. In return Italy was prepared to promise neutrality for the duration of the war, and to renounce for this period the construction in her own favour of the provisions of the Triple Alliance Treaty. In spite of the extent of these demands, they were not flatly refused by Burian, since the military situation compelled him to continue negotiations, and German statesmen and generals pointed out to him the disastrous consequences which would follow if Italy went over into the enemy camp. The fall of Constantinople was threatening, the Russians were pressing relentlessly forward, Hungary seemed at their mercy, and it might happen that a declaration of war by Italy would be followed by Rumania, and even by Bulgaria. Then the hemming-in of the Central Powers would be complete and the seal would be placed upon their ruin. Burian could not cast doubt upon these arguments; it was not without influence upon him that Conrad now advocated every concession to Italy. Burian therefore increased his concessions, but did not yield all that Italy demanded. He retreated, rather, step by step, always led by the hope that a new turn would be given to events in the theatre of war; he sought to hold the Italians in place without rebuffing them. But since the latter did not count upon achieving their demands from Vienna, and were convinced that the Habsburg Monarchy would take back again what had been squeezed from it in the hour of need, should the military situation take a more favourable turn, they determined to bring to a conclusion the negotiations which they had long carried on with the Entente Powers. On April 26 1915 the Treaty of London was signed, which pledged Italy to enter the war by the side of her new allies at the end of a month's interval. As compensation for this, it contained the assurance of an extension of territory for Italy going far beyond that which she had demanded from Austria-Hungary as the price of maintaining neutrality.

Having come to terms with the Entente Powers, Italy resumed negotiations with the Vienna Cabinet, not with the intention of pursuing them to any profitable end, but rather in order to find in the refusal of the Vienna Government to fulfil Italy's demands just grounds for going over to the enemy camp, and time to complete her warlike preparations. It was, therefore, in vain that Burian, under pressure of both the Austro-Hungarian and German army commands and of the German Government, went further and further in concessions to Italy. On April 21 1915 Sonnino declared that the points of view on either side were too wide apart for the differences to be bridged over; and on April 25 the Duke of Avarna, the Italian ambassador, who had up till then worked untiringly for a friendly understanding, expressed his opinion that a breach was inevitable. Even Prince Bülow, who continued the negotiations at Rome up to the last moment, let it be understood that he no longer believed the Italians to be in earnest in seeking a compromise. On May 3 1915, in fact, the Italian council of ministers resolved to denounce the existing alliance with Austria and to claim full freedom of action for Italy. In vain the Vienna Cabinet made yet further concessions, so that in the end these included almost everything that the Italians had demanded. Sonnino continued indeed to negotiate, but he was always finding fresh reason for postponing a decision. On May 20 1915 the Italian Government received from the Chambers the extraordinary powers necessitated by the approaching conflict, and on the 23rd war was declared by Italy on Austria-Hungary.

Italy Declares War.

One of the chief reasons which had decided Burian to offer such far-reaching concessions to Italy in April and May 1915 was the pressure from the military higher command, and especially Conrad, who never ceased to insist in his memoranda that Italy's entry into the war would be followed by that of Rumania, and on this account adjured Burian to make every sacrifice in order to avert the otherwise unavoidable catastrophe by winning over Italy. That his fears were well grounded was all the less doubtful, since it was already known in Vienna by Feb. 1915 that on Feb. 6–23 the agreement concluded in Sept. 1914 between Italy and Rumania as to their attitude in the war had been renewed for four months and had received an extension to the effect that the two Governments bound themselves to render each other mutual aid in the event of an unprovoked attack on the part of Austria-Hungary. The negotiations as to the cession of Austrian territory, which had been begun with Italy under the impression of this news, had now as their result that Rumania, too, raised the price of her continued neutrality. It was no longer only the Bukovina that was mentioned, but also Transylvania. But Tisza declared that he would not sacrifice a square yard of Hungarian soil, and the Vienna Cabinet agreed with him. The result was an increase of the influence of the Triple Entente in Rumania, which was further heightened by Russia's victories in the Carpathians and the breakdown of the negotiations conducted between Burian and Sonnino. The climax of this spirit of hostility to the Central Powers in Bucharest was reached on April 27 1915, when the Italian minister announced a declaration of war on the Habsburg Monarchy to be unavoidable. Only one thing could restrain Rumania, and decide her to maintain her neutrality: a great victory of the Central Powers over the Russians. And this now happened: the break-through at Gorlitz, on May 2 1915. Its effect was felt at once. Bratianu, the Rumanian minister-president, now declared that the position was indeed very critical, but that he hoped to contrive to maintain neutrality; further news of the successes of the German and Austro-Hungarian troops in Galicia and Poland contributed towards strengthening the Rumanian Government in their resolve not to give up their neutrality for the present. In these circumstances even the Italian declaration of war did not alter the Rumanian position, but the altered conditions of the war certainly influenced the attitude of the Vienna Government. Its interest in Rumania now sensibly declined, since her neutrality seemed assured by the military situation.

Equivocal Attitude of Rumania.

The desire of the Central Powers to arrive at a decision in their negotiations with Bulgaria became all the more urgent. Since Jan. 1915 the Turks had been successfully defending the Dardanelles against the attacks of the allied Western Powers, but their position was menaced by the fact that they lacked arms and munitions, which Germany had bound herself to provide by the terms of a treaty concluded on Jan. 11 1915, with which Austria-Hungary associated herself on March 21 1915. It was therefore necessary to establish secure communications with the Turks, and since all the efforts of the Central Powers to obtain the transport of arms and munitions through Rumania remained fruitless, it was necessary to try and make sure of a way through Bulgaria into Turkish territory. The adherence of Bulgaria would also give a further advantage. With Bulgaria in alliance with the Central Powers, Rumania would be less inclined to risk join-

Negotiations with Bulgaria.

ing their enemies, as in that case she would have to reckon with Bulgaria, which had not forgiven the wounds inflicted by the provisions of the Treaty of Bucharest in 1913.

It was not an easy matter for the Cabinets of Vienna and Berlin to win over the Bulgarians. Both the King and Radoslavov distrusted the Rumanians and Turks, and feared the Greeks and Russians. Moreover, the far-reaching offers of the Entente Powers were not without influence upon them. Their attitude in their dealings with the representatives of the Central Powers was guarded, and they kept increasing their demands. As early as the end of 1914 the Vienna Government, in view of the unfavourable military position in Serbia and Galicia, and in consequence of the pressure exerted upon it not only by the German politicians and military commanders, but also by Conrad, had declared its readiness to concede to the Bulgarians, in the event of their entry into the war on the side of the Central Powers, the possession of those Serbian territories to which they advanced historical and ethnographical claims; only, however, so far as they should occupy them with their own troops during the course of the war. The negotiations started at the beginning of 1915 on this basis were protracted by the Bulgarians, for in view of the unfavourable military situation of the Central Powers at the time, King Ferdinand and Radoslavov did not think it expedient to enter into permanent engagements. They therefore declared that they could promise only to remain neutral, but demanded in return considerable extensions of territory in Macedonia, increasing their claims in March and April under the impression of the Russian victories in the Carpathians and the danger threatening Turkey from the Western Powers. Burian, however, held firmly to the position that he could make territorial concessions only in return for active participation on Bulgaria's part. The breakthrough at Gorlitz and the subsequent victorious advance of the Germans and Austro-Hungarian troops also produced their effect in Sofia. The negotiations with the Central Powers were carried on with more zeal; but they failed to reach a settlement, since the demands of the Bulgarians continued to be out of all proportion to any services which they seemed disposed to offer in return. They declined to attack Serbia, refused a military convention proposed to them by the Central Powers, but at the same time increased the price of their continued neutrality. The entry of Italy into the war against the Central Powers, and the increasingly extensive offers on the part of the Entente, added to the difficulty of the negotiations between Vienna and Sofia. But gradually the conviction gained ground in Sofia that adherence to the Central Powers would serve the interests of Bulgaria better than an alliance with the Entente. For it would be easy for the former to concede the extensions of territory desired by Bulgaria in Macedonia at Serbia's expense, whereas the Entente Powers were bound to fear that similar concessions on their part would give offence to their faithful ally Serbia. The Triple Entente failed in their efforts to persuade the Serbs to consent to this sacrifice by promising them, in the event of ultimate victory, the possession of Bosnia, Herzegovina and Dalmatia, for Bulgaria demanded immediate possession of the Macedonian territories promised her, while Serbia wanted the transfer of these territories to be postponed until she herself should have secured the extension of territory promised to her by way of compensation.

Treaty with Bulgaria.

It was only when the continued victorious advance of the Germans and Austro-Hungarians in Poland made the prospects of the ultimate victory of the Central Powers in the World War seem very favourable, that the advantage to be gained by joining them was definitely recognized at Sofia. From July 1915 onwards negotiations were energetically carried on. The Central Powers insisted on the signature of a military convention in addition to the treaty of alliance, and that Bulgaria should at the same time conclude a treaty with the Turks. After innumerable difficulties had been surmounted, the treaties between Austria-Hungary and Bulgaria were signed on Sept. 6 1915. The most important article of one treaty contained a guarantee by Austria-Hungary of the independence and integrity of Bulgaria against any attack not provoked by Bulgaria herself, this guarantee to be valid for the duration of the alliance, *i.e.* till Dec. 31 1920, and after that for a year, and so on until the treaty should be denounced in proper form. Bulgaria, for her part, undertook to give Austria-Hungary proportionate armed assistance in the event of the monarchy being attacked by a State bordering on Bulgaria, and demanding her aid. The second agreement, signed on the same day, contained a pledge from Bulgaria that she would take the offensive against Serbia, in return for which what is now Serbian Macedonia—the so-called "disputed" and "non-disputed" zones, as established by the Serbo-Bulgarian Treaty of March 13 1912—was promised to her. In the meantime it was agreed that, in the event of an attack by Rumania on Bulgaria or her allies—including the Turks—which should not have been provoked by Bulgaria, Austria-Hungary would consent to the recovery by Bulgaria of the territory ceded by her to Rumania by the Peace of Bucharest, and a rectification of the Rumano-Bulgarian frontier as defined by the Treaty of Berlin. A similar promise was made to Bulgaria, under the same conditions, with regard to the territory ceded by her to Greece by the Peace of Bucharest. The military convention signed on the same day settled the provisions for the carrying-out of the impending joint offensive against Serbia. The negotiations between the Turks and Bulgarians, which had been going on for a year past, were also brought to a conclusion on Sept. 6, thanks to persistent pressure from the Central Powers. Turkey gave in on the essential point by agreeing to a rectification of the frontier in favour of Bulgaria on both banks of the Maritsa.

The significance of the adhesion of Bulgaria to the Central Powers lay in the facts that it secured their communications with Turkey, and also the possibility of a victorious campaign against Serbia. The campaign now began and proceeded according to programme. Though valiantly defended by the Serbs against overwhelming numbers, their country fell, towards the end of 1915, into the hands of the Central Powers and Bulgaria. Shortly afterwards Montenegro shared the same fate.

The Polish Question.

The year 1915 also brought "Congress Poland" into the possession of the Central Powers. After the fall of Warsaw (Aug. 5 1915) General Governments were set up on behalf of Germany at Warsaw and on behalf of Austria-Hungary at Lublin, to which all governmental powers were handed over. At first the Central Powers had not contemplated the permanent acquisition of "Congress Poland." It was merely considered as a pawn and an item for compensations at the end of the war. But after the fall of Warsaw, the Cabinets of Vienna and Berlin tried to arrive at an agreement as to the future destiny of Poland. The most diverse solutions were discussed, but no definitive agreement was arrived at by the end of the war. The idea of handing Poland back to Russia was indeed repeatedly advanced by Germany—both in the year 1915 and again very actively after July 1916—when Stürmer was at the head of foreign affairs in the empire of the Tsar. But since the condition of such a solution—namely a total separation of Russia from the Entente—could not be brought about, it was allowed to drop. The plan of dividing the whole of the conquered territory of Poland between Austria-Hungary and Germany was also considered. But insuperable difficulties arose in the course of the negotiations, particularly with regard to the frontiers of the respective territories. It was also foreseen that the Poles would not voluntarily submit to a new partition of their country and that they would struggle for its reunion. It was feared, moreover, that far-reaching differences between the Allies would be revealed the moment economic and military questions should come under discussion. The idea of annexing "Congress Poland" to Germany, first ventilated by a section of public opinion and in military circles in Germany, was rejected not only by the Vienna Cabinet but also by the German Imperial Chancellor, since he feared the increase of Polish influence in Germany that would be bound to follow. The plan advocated for a time by Bethmann Hollweg,

of founding an independent Polish buffer state, which should be in economic, political and military alliance with the Central Powers, also split upon the opposition of the Vienna Government. Thus the union of "Congress Poland" with the Habsburg Monarchy, which Burian had proposed in Aug. 1915, and which had been advocated by the writings of Count Andrassy among others, stood out more clearly as the only possible solution of the Polish question. But this, too, presented great difficulties on closer examination. There were adherents of the idea of a personal union and on the other hand of an actual union; among the latter were those who were in favour of a trialistic form for the new greater Austria-Hungary, and those who advocated the incorporation of Poland in the Austrian State.

Under the influence of the Hungarian Government, whose spokesman, Count Tisza, protested in the strongest terms against the organization of the monarchy on a trialistic basis, the idea now prevailed of annexing Poland to Austria-Hungary and granting to the united territory of Poland, with the addition of Galicia, a far-reaching autonomy. This had the further object of diminishing the damage to the interests of the German-Austrians which was feared by wide circles in Austria and Germany. Since the autumn of 1915 negotiations were carried on between leading statesmen of Germany and Austria-Hungary on this basis. But the more deeply the question was gone into the greater were the difficulties which presented themselves. Bethmann Hollweg declared that the German people could only agree to such a strengthening of Austria-Hungary in the event of the German Empire coming out of the war with an equally large increase of territory. Economic and military objections were also advanced on the German side, and as a solution it was proposed to incorporate a small portion of "Congress Poland" with Austrian Galicia, and out of the greater part of the rest to create a Polish State independent in form but in reality under the protectorate of Germany. But this proposal was firmly rejected by the Vienna Government, which for its part advanced the idea of a genuinely autonomous State comprising the whole of Polish territory, which should be allied by a long-term economic and military agreement with both the Central Powers equally. But it was impossible to win the consent of the Berlin Government to this plan.

Such was the position when the Austro-Hungarian troops were defeated at Lutsk. The result of this was that in Aug. 1916 the Germans carried the day with their proposal to found an independent State, practically comprising the former "Congress Poland" under a hereditary constitutional monarchy, but subject to the most far-reaching limitations in military and economic matters. On the Austro-Hungarian side the bestowal of the crown of Poland on a member of the family of Habsburg-Lorraine was waived. A more exact definition of the sphere of influence of the Central Powers was reserved for further discussion. But their subsequent course showed that the opposition of interests was too deep-seated for it to be possible to settle matters in a hurry. In Oct. 1916, therefore, they came to an agreement for the present to shelve the question of an independent Polish State. But in order to calm the Poles, who were anxious about their fate, and to secure the assistance of their armed forces for the Central Powers, a proclamation was issued on Nov. 5 1916, in which a prospect was held out of the restoration of an independent Poland as a hereditary constitutional monarchy closely attached to the Central Powers. But the two military governments at Warsaw and Lublin continued to administer the country.

Rumania Joins the Entente.

Even before this agreement had been arrived at, Rumania had actually gone over to the Entente camp. The Central Powers had indeed not been wanting in offers to the Rumanian Government between Italy's entry into the war (March 1915) and the conclusion of the treaties with Bulgaria (Sept. 1915), but had made their concessions conditional on the active intervention of Rumania on their side. But the leading statesmen of Bucharest would not agree to this; for in spite of the great military successes of the Central Powers, their final victory seemed to them doubtful. They accordingly continued to insist on important cessions of territory in the Bukovina and Transylvania by Austria-Hungary in return for a continuance of their neutrality. To this, however, Burian, strongly influenced by Tisza, refused to agree, although not only the German Government but also Conrad von Hötzendorff actively supported Rumania's demands. Thus the negotiations, which had been reluctantly continued by Burian, remained without results. Even Bulgaria's adhesion to the Central Powers, and the successful campaign against Serbia, did not produce any change in the attitude of the two Governments. The majority of Rumanian politicians counted on a rapid change in the military situation, and the Entente diplomatists made every effort to confirm them in this belief. But the Rumanian Government maintained its conviction that it must for the present preserve its neutrality. It was the Russian victories at Lutsk and Okna which first led to a change in their views. At the end of July 1916 the Vienna Cabinet was aware, from its ambassador, Count Czernin, that preparations for war were being completed in Bucharest, that negotiations were being carried on with the Entente Powers as to the conditions of going over to them, and that the probability was that Rumania would draw the sword as soon as the harvest was garnered. In spite of this, and though the news during the next few weeks was more and more unfavourable, Burian firmly refused the demands made by Rumania for the maintenance of their neutrality, and was not to be moved from his resolve even by the German Government and Conrad von Hötzendorff. And so towards the end of August the union of Rumania with the Entente Powers was accomplished, in return for far-reaching territorial concessions granted by them to their new ally at the expense of the Austro-Hungarian Monarchy. On August 27—on the day of Italy's formal rupture with Germany—followed Rumania's declaration of war on Austria-Hungary, and hostilities began without delay. But the hope of the Entente that Rumania's entry on their side would quickly decide the war in their favour was not fulfilled. After preliminary Rumanian successes against the weak troops of the Habsburg Monarchy, the armies of the Quadruple Alliance, fighting under German leadership, achieved a decisive victory. On Dec. 6 1915 Bucharest was taken, and at the beginning of Jan. 1917 two-thirds of Rumania was occupied.

New Agreements with Turkey.

Turkey's danger had grown through the entry of Rumania into the war on the side of the Entente Powers. She, therefore, addressed herself to the Central Powers with fresh demands. So early as Sept. 28 1916 Germany assured the Porte that, in accordance with her treaty engagements, she would not conclude a separate peace, would allow Turkey a share, proportionate to her military efforts, in any territorial conquests, and would not agree to any peace so long as Turkish territory was occupied by the enemy. Soon afterwards, on Jan. 11 1917, a further agreement was arrived at between these two Powers, in which the abolition of the Capitulations, which Turkey found oppressive, was contemplated. The provisions of these two treaties were expanded in a manner favourable to Turkey on Nov. 27 1917. The Austro-Hungarian Government, after long hesitation, associated itself on March 22 1917 with the German settlements of Sept. 28 1916 and Jan. 11 1917. But her ratification was not given. A treaty was signed between Austria-Hungary and Turkey on May 30 1918 as to the question of the Capitulations, which corresponded to the Turco-German one of Nov. 27 1917, and by which Austria-Hungary pledged herself not to sign any peace which should reëstablish the Capitulations.

First Peace Proposals.

The success of the Central Powers in Rumania was a ray of light in the last days of the Emperor Francis Joseph I., who had entered the war with a heavy heart, and always remained full of anxious care as to the fate of his empire. His armies and those of his allies had achieved decisive victories in several theatres of war in the course of the year 1916; they had occupied new territories, and in other quarters had successfully repelled the increasingly formidable offensive of their enemies. The battles on the

Isonzo had thrown the heroism of the Austro-Hungarian troops into particularly clear relief. But the number and military efficiency of their enemies increased, and since Great Britain commanded the sea and the United States supported them more and more lavishly, the Entente armies had at their disposition vast masses of arms and munitions of every kind and also immense supplies of foodstuffs. The Central Powers, thrown back upon their own industrial resources, and hampered in the import of foodstuffs and the production of weapons by the British blockade, could not keep pace in the race. For this reason the desire to put an end to this internecine struggle of the nations grew from month to month, especially in Austria-Hungary, where from the beginning of the war a great part of the population had only fought unwillingly for interests which were not regarded as their own. In the course of the year 1914 Francis Joseph, for his part, had not refused to listen to suggestions for a peace which should take into account the most important interests of his empire; he had approved the numerous proposals for peace which in the years 1915–6 had come from more or less authoritative quarters; but he had always insisted most strongly that these negotiations must be conducted in full agreement with his allies, and especially with Germany. But all these peace proposals had proved abortive, since neither Germany nor Austria-Hungary saw the possibility of ending the war on any terms commensurate with the military situation and their desires. But in Oct. 1916, in order to prove to the public opinion of the world that it was not the insatiability of the Central Powers which stood in the way of peace, Burian proposed to the German Imperial Chancellor, at the general headquarters at Pless, that the Quadruple Alliance should inform their enemies, through neutral channels, of their conditions of peace, and also publish them, in order to enlighten their own peoples as to their war aims and win over the neutral Powers to an active intervention with the enemy Governments. Bethmann Hollweg and the other German statesmen agreed in principle with Burian's idea. But they declined, for their part, to communicate their concrete peace conditions, since they felt themselves bound, especially in the Belgian question, to advance demands which their enemies, and especially Great Britain, could not possibly accept. On this point excited debates took place and serious conflicts between the Vienna and Berlin Cabinets, in the course of which the Austrians demanded the recall of Tschirschky, the German ambassador at the Court of Vienna, who represented the German point of view with uncompromising harshness. Even the sovereigns of Austria-Hungary and Germany took part in this conflict. The Emperor William sought insistently to convince his ally that Germany could not fall in with Burian's plan. It was one of Francis Joseph's last acts to invoke every means in order to accomplish a settlement of the outstanding difficulties. It was only after long negotiations—Francis Joseph having in the meantime died on Nov. 21 1916—that it was possible to reach a compromise. It was agreed to submit the proposal of the Quadruple Alliance to their enemies through the neutral Powers, and immediately to enter upon deliberations as to a peace, in which the peace conditions of the Quadruple Alliance should be exactly defined.

Strained Relations with Germany.

The death of Francis Joseph and the accession of the Emperor Charles to the throne of Austria-Hungary notably reinforced the peace party at Vienna. In his very first declarations Charles emphasized his firm intention of doing everything in his power to put an end to the terrible world conflict. In this attitude he was most strongly confirmed by his wife, Zita, by her mother, the influential Maria Antonia of Parma, and by his brothers-in-law, Sixtus and Xavier. On Dec. 12 1916 the peace offer of the Quadruple Alliance was made public. It contained a promise to submit to a conference of the Powers proposals which should aim at assuring to their peoples existence, honour, and freedom of development, and at laying foundations calculated to establish a lasting peace. In conversations with Germany, Austria-Hungary defined her standpoint as follows:—She claimed the integrity of her territory, trifling frontier rectifications as against Russia, a more favourable strategic frontier against Rumania, the cession to Austria-Hungary of a small portion of the territory of the Serbian Monarchy and of larger portions to Bulgaria and Albania, and a more favourable strategic frontier against Italy; in addition to this the economic union of Serbia with the Habsburg Monarchy, and Albanian autonomy under an Austro-Hungarian protectorate. Independently of the peace activity of the Quadruple Alliance, Mr. Woodrow Wilson, who had shortly before been re-elected President of the United States, on Dec. 18 1916 invited the belligerent Powers to communicate their peace terms, and had a note handed in at London in this sense on Dec. 21. Both proposals, however, were declined by the Entente Powers. On Dec. 30 1916 Briand, on the part of France, declared the peace offer of the Quadruple Alliance to be a war manoeuvre, and that all negotiations were useless, so long as no security was given for the restoration of violated rights and liberties and the recognition of the right of peoples to self-determination. In the note drawn up in concert by the Entente Powers on Jan. 12 1917, in answer to President Wilson's communication of Dec. 18, all the blame for the outbreak of war was imputed to the Central Powers, and the demand was formulated, among other things, for compensation for all war damages, the restoration of Alsace-Lorraine to France, and from Austria-Hungary in particular proportionate cessions of territory to Italy as well. The German Government, which had by now fallen into more and more obvious dependence on the higher army command, thereupon resolved to carry on the war by the employment of the most extreme measures, the most important and most promising of which was indicated in authoritative quarters to be unlimited submarine warfare.

Peace Proposal of Dec. 1916.

Baron Burian, meanwhile, had ceased to be Austro-Hungarian foreign minister on Dec. 22 1916, being succeeded by Count Ottokar Czernin, the former ambassador at Bucharest. Austro-Hungarian statesmen generally did not share the exaggerated expectations of German military circles as to the effects of the submarine campaign, and Czernin in particular gave open expression to his doubts about the subjugation of England within a few months, which the German authorities seemed to regard as certain. He drew attention to the danger of an active intervention of the United States, if unlimited submarine warfare were entered upon. The Emperor Charles shared his minister's views. But the continual pressure of German statesmen and the German higher command, powerfully supported by the Emperor William, at last succeeded in obtaining the consent of the Austro-Hungarian Government to the unlimited submarine warfare. The war was resumed by Germany and her allies by land, by sea and in the air. But the hope of forcing their enemies to their knees by decisive successes was not realized. During the year 1917 there were indeed moments in which it looked as if the final decision would be in their favour. But their enemies, in spite of all the successes of the Central Powers and their allies, rejected all thoughts of a peace unsatisfactory to them.

Czernin Succeeds Burian.

The opening of unlimited submarine warfare was followed immediately by the rupture of diplomatic relations between the Cabinets of Berlin and Washington, and on April 6 1917 by the declaration of war on Germany by the United States. It was not till Dec. 7 1917 that the United States declared war on Austria-Hungary. Meanwhile, since the successes of the submarine warfare, though in themselves considerable, did not produce the result foretold by Germany, the Emperor Charles's inclination towards peace grew from month to month. Under the influence of his *entourage* he determined, by secret negotiations with the enemy, to work for a peace which should include a guarantee of the integrity of the Habsburg Monarchy by the Entente Powers. His brother-in-law, Prince Sixtus of Bourbon Parma, undertook the rôle of mediator. On March 24 the Emperor Charles empowered him, by letter, to declare to M. Poincaré, President of the French Republic, that in order to obtain peace he would

American Declaration of War.

Secret Peace Proposals.

exert every effort in his power to support the just claims of France to Alsace-Lorraine *vis-à-vis* his allies. In other questions too, notably in that of Belgium, the Emperor Charles showed a wish to further the desires of the enemy Powers as far as possible. On the other hand, there was no mention in Charles's letter of any readiness to cede Austrian territory to Italy. Count Czernin, who was well informed as to essentials in the negotiations, but was unacquainted with the text of the imperial letter, endeavoured in the meanwhile to win over the German Government to the idea of peace. On March 27 1917 an agreement was signed at Vienna between him and Bethmann Hollweg which provided for a minimum and maximum programme. In the former the restoration of the territorial *status quo ante bellum* of the Central Powers in the E. and W. was laid down as the condition precedent to their evacuation of the occupied provinces of Russia (except Poland), Serbia, Albania, Greece and Rumania; in the latter, which was to hold good in the event of the war taking a more favourable turn, provision was made for a permanent acquisition of enemy territory in proportion to their respective military achievements. In this event Germany's field of expansion was to be in the East, Austria-Hungary's in Rumania.

German Peace Programmes, 1917.

Shortly afterwards, April 3 1917, the Emperor Charles and Count Czernin arrived at Homburg as guests of the Emperor William. Czernin here came forward with a proposal (the connexion with Prince Sixtus's *démarche* being noteworthy) that Germany might make concessions to France in Alsace-Lorraine, and as a substitute for her losses in the West take permanent possession of a Poland supplemented by Galicia. These plans found a basis in the prospect of concluding a favourable peace with Russia, which had opened up shortly before the abdication of the Tsar Nicholas II. in March. To reinforce his efforts, Count Czernin, on April 14, sent to the Emperor William a report, drawn up by himself and the Emperor Charles in person, in which the internal situation of the Habsburg Monarchy was painted in the blackest colours, and its collapse, involving a revolution and the downfall of the dynasty, was represented as imminent. At the same time Czernin renewed in authoritative quarters in Germany his offer to compensate the German Empire for eventual losses in Alsace-Lorraine by the permanent acquisition of Poland enlarged by the addition of Galicia. But the Emperor William and his counsellors refused to open negotiations with the enemy on this basis, and urged the continuation of the war. It soon afterwards became clear that the secret negotiations conducted by Sixtus of Parma with the Entente Powers would not lead to the results desired by the Emperor Charles and Czernin. For Italy held by her hond, and demanded the cession of all those provinces of the Habsburg Monarchy which had been promised her by the Treaty of London of April 26 1915. To this, however, the Emperor Charles, particularly in view of the military situation at the time, neither would nor could consent.

The negotiations with the Western Powers having thus for the present led to no tangible results, the Emperor Charles and Count Czernin decided at Kreuznach (May 17–18 1917) to come to an agreement with the German Government, in which there was no further mention of the cession of Alsace-Lorraine, but in which it was stipulated by Austria-Hungary that not only should her integrity be guaranteed but she should receive considerable accessions of territory in the Balkans. Germany, furthermore, agreed in the event of her being able to carry out "the territorial incorporation (*Angliederung*) of Courland and Lithuania, together with the dependence (*Anlehnung*) of Poland contemplated on the German side," that "Rumania so far as occupied, with the exception of the Dobruja (frontier anterior to 1913) and a border strip to the S. of the Cernavoda-Constantza railway, falls as a separate State into the Austro-Hungarian sphere of interests, subject to a guarantee of Germany's economic interests in Rumania." On the fulfilment of these conditions Austria-Hungary consented to renounce her condominium in Poland, and promised to declare her *désintéressement*, political and military, in Poland. On June 8 1917 the Emperors William II. and Charles signed an agreement as to Poland's military forces, by which their organization was placed entirely in the hands of Germany.

Kreuznach Agreement with Germany.

The war continued. The Quadruple Alliance waged it with the exertion of all its military strength, and even now gained not inconsiderable successes. On the western front the Germans held at bay the attacks of the French and British troops, lavishly furnished with war material. On the eastern front the armies of the Alliance fought successfully against the Russians. In the S. the armies of Austria-Hungary, stiffened by German troops, undertook an invasion of Italy which led to the occupation of further Italian territory. But all these successes did not suffice to compel a desire for peace on the part of the enemy, while, in the countries of the Quadruple Alliance, war weariness, furthered by a skilfully managed propaganda on the part of the Entente, kept spreading to wider circles among the soldiers and citizens of the Central Powers and their allies. This feeling among the people, and the recognition of the fact that the war could only be ended by diplomatic means, decided Czernin to resume with the greatest energy his efforts to achieve a peace which should preserve the vital interests of the monarchy. In this he was strongly supported by the declaration made by the majority in the German Reichstag on July 19 1917 in favour of a peace by agreement, in which the forcible acquisition of territory, and oppressive political, economic and financial measures were repudiated, and the freedom of the seas and the renunciation by the enemy of the economic blockade of the Central Powers were demanded. Yet neither the Pope's official efforts for peace nor the secret Revertera-Armand (July–Aug. 1917) and Mensdorff-Smuts (Dec. 1917) negotiations led to tangible results, since the enemy had exact information as to the critical internal situation of the Powers of the Quadruple Alliance, and, counting upon the strong support of the United States for the following year, made conditions to which, in view of their favourable military situation at the end of the year 1917, Germany and her allies would not accede. At this time, moreover, the prospect was opening to them of concluding a favourable peace with their enemies in the E. which would enable them to fall with their full strength upon their enemies in the West.

Growing War Weariness.

The revolution which had taken place in Russia in March 1917 had not brought peace; on the contrary, the numerous negotiations which took place between the Central Powers and Russia, having as their aim the conclusion of a separate peace, dragged on inconclusively. The war went on; it was waged successfully by Germany, and brought wide territories in the East into the possession of the allies. But a decisive change took place for the first time in the attitude of the Russian politicians in Nov. 1917, when the second phase of the Russian revolution—the "social revolutionary" phase led by Kerensky—was succeeded by a third, that of the "Bolsheviks," led by Lenin and Trotsky. As early as the end of Nov. 1917 the new Government summoned all the combatant Powers to enter immediately upon an armistice and begin negotiations for the conclusion of a general peace, which should assure to every nation freedom of economic and cultural development. When the Entente Powers refused to comply with this summons, the Russians on Dec. 3 entered into a suspension of hostilities with Germany and her allies, which was to last till Dec. 17. On Dec. 15 the suspension of hostilities was succeeded by an armistice, which was to last till Jan. 14 1918 and then be continued with the right to denounce it on seven days' notice. Peace negotiations began on Dec. 22 at Brest-Litovsk. They were conducted in public. The upshot was that on Dec. 25 the Quadruple Alliance accepted the Russian proposals for the conclusion of a peace without annexations and indemnities as the basis for a general peace. At the suggestion of the Russian delegates, the negotiations were suspended for ten days and a request was addressed to the enemies of the Quadruple Alli-

Effect of Bolshevik Revolution

Negotiations at Brest-Litovsk.

ance that they should take part in further deliberations on the basis of the resolutions adopted on Dec. 25. But the Entente Powers refused. Thereupon negotiations were begun (Jan. 9 1918) for a separate peace between Russia and the Quadruple Alliance. But they did not run so smoothly as the majority of Austro-Hungarian politicians had hoped. Trotsky, the chief of the Russian delegation, demanded full freedom for the plebiscites to be held in the Russian provinces occupied by the Central Powers, and with this object proposed that their troops should evacuate them. On the rejection of this proposal by the German and Austro-Hungarian delegates, Trotsky protracted the negotiations in order meanwhile to introduce Bolshevik ideas into the territories of the Quadruple Alliance. The progress of the negotiations was hampered by quarrels among the Russians, and by the appearance at Brest-Litovsk of an Ukrainian delegation which pressed for the establishment of a Russian federal republic. Since on this question no agreement could be reached, the representatives of the Ukraine, on Jan. 24 1918, announced the complete independence of the Ukrainian People's Republic, and on Feb. 9 concluded a separate peace with the Quadruple Alliance, which, so far as Austria-Hungary was concerned, left the frontier between the two States unchanged. Inspired by his eagerness to bring to the starving population of Austria, and above all to the inhabitants of Vienna, the longed-for "bread peace," which stipulated for the delivery of foodstuffs from the Ukraine, Czernin, in compliance with the violent desire of the Ukrainian delegation, carried out their demand for the incorporation of the district of Cholm in the newly created republic, and for the erection of East Galicia into an autonomous Austrian crown territory.

Treaty with the Ukraine.

The negotiations with Russia had meanwhile been continued. Czernin, zealously seconded in his efforts for peace by the Emperor Charles, pressed for a conclusion, but met with determined opposition from the German negotiators. On Feb. 10 1918 Trotsky declared that Russia, renouncing a formal treaty of peace, regarded the state of war against the Quadruple Alliance as at an end, and would reduce her troops to a peace footing on all fronts. But since this solution did not meet with the whole-hearted consent of the Central Powers, Germany resumed the struggle. The Austro-Hungarian troops did not enter into the war against Soviet Russia, but after a few days joined the march of the German troops into the Ukraine. The Russians, defeated by Germany in the field, now changed their tactics and declared themselves prepared to conclude a formal peace, which was signed on March 3 1918 at Brest-Litovsk. It brought the Habsburg Monarchy no accessions of territory, but, by the official retirement of the Russians from the ranks of their enemies, it involved a considerable strengthening of the Quadruple Alliance.

Peace of Brest-Litovsk.

Poland had become independent of Russia by the provisions of the Peace of Brest-Litovsk; but this did not settle the Polish question. The negotiations conducted by the Cabinets of Vienna and Berlin as to the fate of Poland in the spring and summer of 1917 led to no issue, since the conflicting interests of the two Powers concerned were shown to be irreconcilable. The plan advocated by Austria, that the Archduke Charles Stephen should be made regent, and afterwards king, was accepted neither by the Emperor William nor by the German Government. In the autumn of 1917 the decision made earlier in the year to abandon Poland to Germany and compensate Austria-Hungary in Rumania was given up, and the Austro-Polish solution advocated by the Emperor Charles and Czernin was approved in principle. In the negotiations which followed as to the carrying-out of this plan, however, the old opposition of interests again became apparent. Germany declared that she would make her acquiescence in the Austro-Polish solution contingent upon the cession to her of large portions of Polish territory, as "rectifications of frontier," and, beyond this, upon her retaining a decisive influence upon the utilization of the economic and military forces of a Polish State which was not to be incorporated in Austria-Hungary but merely joined to her by a personal union. To this, however, the Vienna Government would not agree, and once more the attempt to reach a definitive solution of the Polish question had broken down. The Poles, anxious about their future and keenly desirous to make it as favourable as possible to themselves, took advantage of these differences to continue negotiations with both sides, in order to secure for their State the widest possible territorial extension and the greatest possible measure of independence. They resolutely protested against the cession of the district of Cholm to the Ukraine, and on March 4 1918, with the aid of the Poles in the Habsburg Monarchy, they succeeded in obtaining the signature, by the Powers concerned in the conclusion of the Peace Treaty of Feb. 9, of a protocol in which it was laid down that the frontiers between Poland and the Ukraine were to be settled by a new agreement, arrived at with the coöperation of the Poles, and perhaps to be altered in favour of the Poles. The negotiations between the Cabinets of Vienna and Berlin as to the future destiny of Poland still went on. The former clung to the Austro-Polish solution, but it was evident from many indications that the German Government showed less and less inclination to consent to it. In July 1918, after the luckless Austrian offensive in Italy, the German Imperial Chancellor, Count Hertling, declared that he would no longer recognize the Austro-Polish solution. Poland was to have the free choice of her future form of government, but before its establishment must come to arrangements with the Central Powers, permanently calculated to secure their economic and military interests. Austria-Hungary agreed with these proposals in principle. But the negotiations which were now entered upon led, like all the preceding ones, to no definitive results, though they provided the Poles once more with the desired opportunity for fishing in troubled waters.

The Polish Question, 1917.

The ending of the war between Russia and the Quadruple Alliance also compelled Rumania to conclude peace with the victors, having already, on Dec. 17 1917, had to submit to an armistice. After rather long negotiations the peace preliminaries were signed at the château of Buftea near Bucharest on March 6 1918, and on May 7 the definitive peace; but the latter was not ratified by Rumania. Austria-Hungary received a favourable strategic frontier in the Carpathians, important economic concessions, and the promise of an immediate evacuation of the provinces of the Habsburg Monarchy still occupied by Rumania. King Ferdinand had to thank the personal intervention of the Emperor Charles for the fact that he retained his crown.

Peace Treaty with Rumania.

The successes in the East, gratifying though they were in themselves, did not deceive the governing circles at the Ballplatz as to the danger on the verge of which they hovered. They knew that the filling-up of the seriously depleted ranks of the troops, the production of arms and munitions, the provisioning of the soldiers and of the population, would get more difficult every month. Reports kept coming in as to the increasing war-weariness of the troops, and the more and more openly expressed anti-dynastic sentiments of the non-German or non-Magyar portions of the population of the monarchy, as to the correctness of which there could be no doubt. All these reasons increased the desire of the Emperor Charles and of Czernin to bring the war to an end as quickly as possible. As early as the autumn of 1917 the German Government had been informed from Vienna that Austria-Hungary's strength was exhausted, and insistently urged to sacrifices which might content the enemy. The same point of view had been adhered to during the negotiations at Brest-Litovsk. Germany was to find in the East compensations for the cessions which she must make in the West in order to bring the enemy round the peace-table. For the negotiations secretly carried on by several Austro-Hungarian statesmen with the representatives of the Entente States had left no doubt as to the fact that there could be no thought of a serious entry upon peace negotiations on the part of the Western Powers before

Exhaustion of the Monarchy.

Germany should have handed in precise declarations which should meet their views in the questions of Belgium and Alsace-Lorraine. It was, then, very opportune for the Court of Vienna when President Wilson, in his message to Congress of Jan. 8 1918, defined the Fourteen Points, in which he perceived a suitable basis for the establishment of a lasting peace. It is true that several of these points involved considerable damage to Austro-Hungarian interests: but in their entirety they seemed to afford Czernin the possibility of initiating peace negotiations.

Czernin's Peace Efforts, 1918.

He endeavoured in divers ways, and especially through the mediation of the King of Spain, to enter into negotiations with President Wilson, but failed to attain his end. Equally fruitless were the informal conversations carried on by Austro-Hungarian representatives, in intelligence with their Government, with French delegates in Switzerland and other places. Czernin firmly refused the demand of the Western Powers for the conclusion of a separate peace; but he continued his efforts at negotiation, though he knew that German headquarters had prepared a new campaign in the West which was intended to be decisive.

Burian again Foreign Minister.

At the beginning of April 1918, shortly after this German offensive had successfully begun, Czernin emphasized, in an address to a delegation of the Viennese town council, his loyalty to Germany, as proved by his rejection of the French peace offers, which were conditional on the recognition of France's claims to Alsace-Lorraine. Clémenceau, the French prime minister, declared this assertion to be a lie, and, in the course of the publicist feud that followed, published among other things the letter of the Emperor Charles to Prince Sixtus of March 24 1917, in which he alluded to his willingness to advocate with his Allies France's "just claims" to Alsace-Lorraine. The Austro-Hungarian monarch's loyalty to his alliance was thus placed in an equivocal light, and Czernin's refusal to accept full responsibility for the Emperor Charles's proceedings led to his resignation, Count Burian being reappointed as his successor. In order to calm the agitation of the Emperor William and the German statesmen and generals, the Emperor Charles had to make another "journey to Canossa" at Spa, and there, on May 12 1918, he set his signature to agreements for a closer political and military union between the two countries, the coming into force of which would have meant heavy damage to the independence of Austria-Hungary. But since the condition of the validity of this treaty, namely an understanding between the two Powers on the Polish question, broke down, the Spa agreement, too, remained a scrap of paper.

Last Stages of the War.

Meanwhile Germany was putting forth her last strength in the hope of achieving a decisive success. But her initial successes were followed by reverses. Austria-Hungary had taken part in the battles on the western front, but only within modest limits. In June 1918 she attempted a sudden attack on Italy with the principal body of her troops. But here, too, the decisive victory which had been expected was not achieved. These failures, together with the ever-increasing lack of effective soldiers, arms, munitions and foodstuffs, deepened the longing of the peoples of the Habsburg Monarchy for peace. In addition, the Emperor Charles became alive to the more and more open opposition of the non-German and non-Magyar peoples of his dominions, and likewise to the revolutionary spirit which was becoming conspicuous among the working-classes in many places, and he began to tremble for his crown and the fate of the dynasty. In proportion as the German hope of extorting peace by force of arms diminished, a more favourable prospect seemed to open up for the efforts of Austro-Hungarian statesmen to put an end to the war by way of diplomatic negotiations.

Negotiations for Peace.

At the end of July 1918, Baron Kühlmann, the German Secretary of State for Foreign Affairs, had been compelled to resign in consequence of his saying in the Reichstag that an end of the war through a purely military decision could not be expected. But by Aug. 14 Ludendorff himself, who had played a prominent part in bringing about Kühlmann's fall, declared at headquarters in Spa that they could no longer hope to break the military spirit of the foe by force of arms. Thus when Burian again approached the German Government, he no longer met with any opposition on principle. Yet great differences presented themselves in the course of the deliberations as to the course to be adopted. The Germans wanted to wait for an improvement of the military situation in the West and then begin negotiations with the enemy through a neutral Power—Holland or Spain—while Austro-Hungarian statesmen advocated an immediate and open appeal to all the combatant Powers. At the beginning of Sept. 1918 the German Minister Hintze spent some time in Vienna in order to arrive at an agreed course of action. But since this could not be achieved, Burian determined, without regard to Germany's opposition, to have an appeal sent out to all the combatant States for the opening of peace negotiations. President Wilson answered, however, after a few days' interval, that he had repeatedly and in the plainest terms made known the conditions on which he was prepared to consider the conclusion of peace; hence the Government of the United States could not and would not accept a proposal for the holding of a conference concerning a matter in which it had already clearly made known its attitude and aims. And the Cabinets of Paris and London were equally cold. The sole result of Burian's new effort for peace was the increase of the Entente's hopes of victory. On Sept. 15 ensued a violent attack against the Bulgarian army, in the ranks of which war-weariness had for long past made serious inroads. The Bulgarian troops offered but little resistance; great bodies of them laid down their arms, and returned to their homes. The Sofia Government, at the head of which Malinov, who was friendly to the Entente, had for some months taken the place of Radoslavov, resolved to propose an armistice, which was granted on Sept. 29 under conditions which signified for the Central Powers the loss of the Balkans. King Ferdinand abdicated. These events, and the great successes of the English troops in Palestine, produced their effect upon Turkey. At the beginning of October the fall of Enver and Tal'at took place at Constantinople, and thus the way was opened here too for a separate peace. An armistice was concluded between Turkey and the Entente on Oct. 31 1918, which brought the Dardanelles and the Bosporus under their power, and pledged the Turks to break off all relations with the Central Powers.

Break-up of the Monarchy.

Meanwhile the catastrophe had taken place in Austria-Hungary as well. Encouraged by the repeated pronouncements of President Wilson as to the right of nations to self-determination, the separatist ideas of those peoples of the monarchy which did not acknowledge German or Hungarian nationality became more and more articulate. There were disturbances in various parts of the monarchy, and these disruptive influences made it month by month increasingly difficult to keep the army efficient for war. Both Austria-Hungary and Germany now decided to address to President Wilson the offer of an armistice, to be followed by negotiations for peace. To this offer the President at first made no reply; and thereupon the Emperor Charles, in order to save the dynasty, issued on Oct. 16 a manifesto in which he proclaimed that Austria, in accordance with the will of her peoples, was to be erected into a Federal State, in which every race would be free to establish its own form of body politic on the territory occupied by it. But the union of the Austrian Poles with an independent Polish State was not to be anticipated by this. The imperial manifesto was only to apply to Austria. For Hungary, where they were already working for a personal union and for a complete separation from Austria, the manifesto laid stress upon the integrity of the Hungarian kingdom. It thus became clear to the Southern Slavs that they must no longer hope for a realization of their national aspirations within the bounds of the monarchy. But the Emperor Charles's expectation of conciliating the opinion of the Austrian Slavs by means of the manifesto met with no success. President Wilson, too, rejected the Vienna Cabinet's peace offer. He declared

that the Government of the United States had already recognized Czechoslovakia as a belligerent Power and the Czechoslovak National Council as a belligerent Government, as well as the justice of the national aspirations of the Southern Slavs. It was, therefore, for these peoples themselves to decide which of the resolutions of the Austrian Government were acceptable to them. Upon this the request for an armistice made by the Emperor Charles at the beginning of October was declared to be no longer in force. During October independent national representative bodies assembled in Prague, Agram, Laibach and Vienna. The Emperor's dominions thus dissolved and slipped from his grasp. These internal movements led to the disintegration of the armies, which up to this moment had fought bravely. The Governments of the several countries constituting the monarchy, Hungary leading the way, summoned their co-nationals to the defence of their particular frontiers or called them back home. The Emperor Charles tried to save what still could be saved. He was prepared to conclude a separate peace with the enemy on terms which would make possible the continuance of the old monarchy, even though with diminished territory and as a loose aggregation of separate territorial groups under the dynasty of Habsburg-Lorraine.

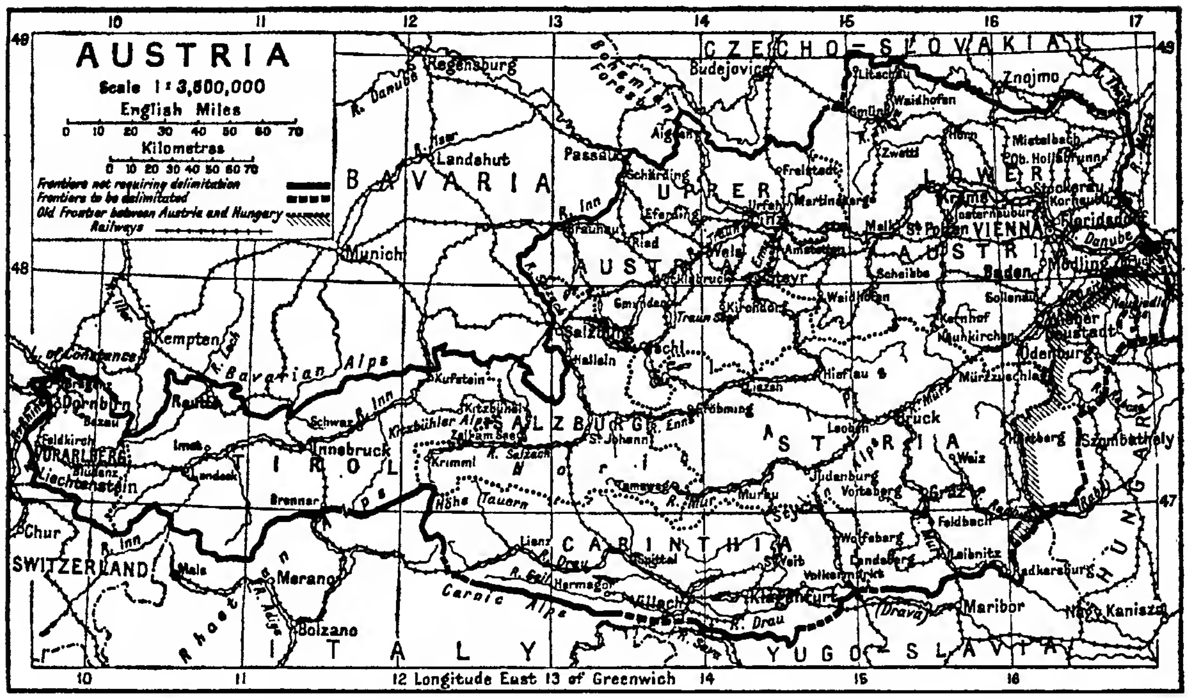
On Oct. 24 Count Julius Andrassy succeeded Burian as Foreign Minister, in order to begin negotiations for a separate peace. Three days later the office of minister-president was given to Heinrich Lammasch, professor of international law and a well-known pacifist. On the same day renewed proposals for an armistice were made to President Wilson, and the peace *pourparlers*, which had never been entirely interrupted, were resumed in Switzerland with representatives of the Entente by various emissaries of the Habsburg Monarchy. Once more, however, they reached no result. At the end of October, after the revolution in Hungary (*see* HUNGARY: *History*), and when increasing numbers of the troops fighting in Italy had started homewards, the Austro-Hungarian army command asked for an armistice from the Italians, who were victoriously advancing against the demoralized and dissolving Austro-Hungarian forces. This was granted on Nov. 3 1918 on conditions of pitiless severity. Austria-Hungary had to reduce her army at once to a peace footing—only 20 divisions were excepted; to evacuate all enemy territories still occupied by her troops; to surrender to the enemy large portions of Austrian territory, and to hand over all war material actually in these territories, as well as the whole of her fleet. By this means all resistance was made impossible even after the expiry of the armistice. Utterly defenceless, the Emperor Charles had to place his own fate and that of the ancient monarchy in the hands of the victors. The latter also demanded free passage for their armies over all roads, railways and waterways of the monarchy. Germany's resistance was thus to be broken by new dangers threatening her from the south. It was only under protest, and bowing to necessity, that the Emperor Charles gave his consent to these demands, which promised to be fatal to his ally. The negotiations for a separate peace were indeed even now still carried on by the diplomatists who remained true to the dynasty, but they hardly met with a hearing from the Entente Powers.

The process of dissolution ran its course in the old monarchy. On Nov. 11 1918 the Emperor Charles renounced all share in the business of government in Austria; the Lammasch Government retired. The Emperor Charles did not, however, renounce his crown. On the following day, in the Austrian National Assembly, a republic was proclaimed (*see* AUSTRIA, REPUBLIC OF), which was at first intended to form a component part of the new German Republic. On Nov. 16 the republican form of government was introduced in Hungary. The ancient Austro-Hungarian Monarchy had thereby ceased to exist, and its rôle as a European Great Power was at an end.

BIBLIOGRAPHY.—Up to 1921 no comprehensive critical account had been published of Austro-Hungarian foreign policy in 1910–8. *The Foreign Policy of Austria-Hungary* (1920), No. I. of the handbooks prepared under the direction of the Historical Section of the British Foreign Office, is a summary survey. The period 1875 to 1914 is treated in an inadequate and one-sided way in Jean Larmeroux, *La Politique extérieure de l'Autriche-Hongrie* (2 vols., 1918). The foreign policy of the monarchy is discussed in its connexion with world politics in, among other works, A. Debidour, *Histoire diplomatique de l'Europe*, vol. iv. (1918); Ernst Reventlow, *Politische Vorgeschichte des grossen Kriegs* (1919); Julius Hashagen, *Umrisse der Weltpolitik*, vol. ii. (2nd ed. 1919); Gottlob Egelhaaf, *Geschichte der neuesten Zeit*, vol. ii. (8th ed.) and Heinrich Friedjung, *Das Zeitalter des Imperialismus*, vol. ii. (1922). Friedrich Wieser's study, *Oesterreichs Ende* (1919), and F. Kleinwächter's book, *Der Untergang Oesterreich-Ungarns*, throw more light on the internal disintegration of the Habsburg Monarchy, but also contain interesting discussions of foreign policy. Meisser's *Politische Chronik der Oesterreich-Ungarischen Monarchie* (1910–8) and Schulthe's *Geschichtskalender* (1910–8) contain extracts from the reports of the proceedings of the delegations and the Austrian and Hungarian parliaments and other important documents and speeches. Of the official publications of the Ministry for Foreign Affairs should be mentioned: *Diplomatische Aktenstücke betreffend die Ereignisse am Balkan, 13. August 1912 bis 6. November 1913* (Vienna 1914); *Diplomatische Aktenstücke betreffend die Beziehung Oesterreich-Ungarns zu Italien in der Zeit vom 22. Juli 1914 bis 27. August 1916* (Vienna 1916); *Diplomatische Aktenstücke zur Vorgeschichte des Krieges 1914* and *Diplomatische Aktenstücke zur Vorgeschichte des Krieges: Ergänzungen und Nachträge zum Oesterreichisch-Ungarischen Rotbuch* (3 parts [June 28–Aug. 27 1914], Vienna 1920). At the instance of the Ministry for Foreign Affairs there appeared Richard Gooss, *Das Wiener Kabinet und die Entstehung des Weltkrieges* (1919). A. F. Pribram's *Die politischen Geheimverträge Oesterreich-Ungarns 1879 bis 1914* (1920) also contains a detailed history of the development of the Triple Alliance treaties (English trans. by A. C. Coolidge, 1920). Valuable information as to Austro-Hungarian foreign policy is to be found in memoirs of German and Austro-Hungarian statesmen and military commanders which have appeared since the end of the war. Among these may be especially indicated: G. Jagow, *Ursachen und Ausbruch des Weltkrieges* (1919); Paul von Hindenburg, *Aus meinem Leben* (1920); Theodor von Bethmann Hollweg, *Betrachtungen zum Weltkrieg* (1919); Erich Ludendorff, *Kriegserinnerungen* (1919); *Urkunden der Obersten Heeresleitung über ihre Tätigkeit 1916 bis 1918* (1920); A. von Tirpitz, *Erinnerungen* (1919); Karl Helfferich, *Der Weltkrieg* (3 vols., 1919); Karl Hertling, *Ein Jahr in der Reichskanzlei* (1919); A. von Cramon, *Unser Oesterreich-Ungarischer Bundesgenosse im Weltkrieg* (1920); Ottokar Czernin, *Im Weltkriege* (1919); Julius Andrassy, *Diplomatie und Weltkrieg* (1920); L. Windischgrätz, *Vom roten zum schwarzen Prinzen* (1920); Auffenberg-Komarow, *Aus Oesterreichs Höhe und Niedergang* (1921); Erich von Falkenhayn, *Die Tätigkeit der Obersten Heeresleitung 1914 bis 1916* (1919); Matthias Erzberger, *Erlebnisse im Weltkriege* (1920); J. V. Szilassy, *Der Untergang der Donaumonarchie* (1921). Separate problems of Austro-Hungarian foreign policy are treated among others by Leopold Chlumecky, *Die Agonie des Dreibundes* (1915); Wilhelm Fraknoi, *Kritische Studien zur Geschichte des Dreibundes* (1916); Severus, *Zehn Monate italienischer Neutralität* (1915); Th. v. Sosnosky, *Die Balkanpolitik Oesterreich-Ungarns seit 1866* (2 vols., 1914); *Die Politik im Habsburgerreich* (1912); Berthold Molden, *Alois Graf Aehrenthal: Sechs Jahre äusserer Politik Oesterreich-Ungarns* (1917). (A. F. PR.)

AUSTRIA, REPUBLIC OF.—The republic of Austria, reconstituted after the collapse in 1918 of the old empire (*see* AUSTRIAN EMPIRE) is bounded on the E. by Czechoslovakia, Hungary and Yugoslavia, on the S. by Yugoslavia and Italy, on the W. by Switzerland, Liechtenstein and the Lake of Constance, on the N. by Germany (Bavaria) and Czechoslovakia.

Under the new régime, Austria had in Aug. 1921, including the Burgenland (which was in process of being handed over by Hungary), an area of 32,491 sq. m., somewhat less than that of Ireland. Its population is less than one-fifth that of England. It belongs almost entirely to the Danubian region and for the greater part to the Eastern Alps; a small part of it embraces the outlying spurs of this mountain system, which form a connexion with the Carpathian; and another part comprises the Austrian Granite Plateau, the most southerly portion of the Boic *massif*. But Austria's frontiers, especially towards the Alps, are not natural boundaries, and their long extension is a source of geographical and economic inconvenience. Czechoslovakia received three minor border territories of Lower Austria; Italy advanced as far as the Adriatic watershed, and even passed beyond it in various places in the basins of the Inn and Drau (Drava); Yugoslavia received South-Eastern Carinthia and Southern Styria as far as the Posruck and the Mur. Thus the closed territories of Tirol and those of the Carinthian basin



and Central Styria were cut off; the two great natural triangular routes, that of German Tirol and that within Austria, and hence also the southern longitudinal railway of the Eastern Alps (Franzensfeste-Marburg) were split up between different states (*see* CARINTHIA, STYRIA, TIROL).

Population.—The territories under Austrian administration in May 1920, which alone could be included in the census of Jan. 31 1920, embraced a portion of Lower Austria belonging to Czecho-slovakia; on the other hand, electoral district No. I. of Carinthia and a few communes of Styria were occupied by the Southern Slavs, and the disputed Burgenland (German Western Hungary) by Hungary. With these reservations the figures in the appended table hold good.

Territory	Area in sq. m.	Pop. Dec. 31 1910.	Pop. Jan. 31 1920.	Density per sq. m.
Lower Austria . .	7,639	3,525,094	3,313,155	434
Upper Austria . .	4,626	853,006	857,234	185
Salzburg . . .	2,762	214,737	213,877	77
Styria	6,304	952,590	946,721	151
Carinthia . . .	3,017	299,091	297,257	99
Tirol	4,787	304,713	306,153	64
Vorarlberg . . .	1,005	145,408	133,033	132
Total . . .	30,140	6,294,639	6,067,430	201
Carinthia, Zone I .	667	72,138	—	—
Burgenland . . .	1,684*	345,082*	—	—
Total . . .	32,491*	6,711,859*	—	—

* Approximate.

The returns show that, in consequence of the war and the shortage of foodstuffs in all countries from 1910-20, the populations of Upper Austria and Tirol decreased greatly during that period (the average decrease was 3·6%). In Vienna, the birth-rate had slightly increased, but in 1921 was still lower than the death-rate. In 1910, the proportion of males and females was as 1,000 to 1,024; in 1920 as 1,000 to 1,089. The nationalities of the inhabitants are not shown in the census of 1920; only the Czechs in Vienna and the Slovenes in Carinthia form important minorities.

The population of the mountainous districts is sparse; only Lower Austria, thanks to Vienna, shows a dense population. Excluding Vienna it would show only 194 inhabitants per sq. m. In the area covered by the census of 1920, 39·8% of the population was in 3,551 communal districts having up to 2,000 inhabitants; 14·1% in 295 such districts having 2,001 to 5,000 inhabitants; 4·8% in 43 districts of 5,001 to 10,000 inhabitants; 2·8% in 13 districts of 10,001 to 20,000 inhabitants; 3·0% in seven districts of 20,001 to 50,000 inhabitants, and 2·5% in two districts of 50,001 to 100,000 inhabitants; 33·0% were, however, in two districts of over 100,000 inhabitants (Vienna and Graz). In 1910 94·12% of the population was Roman Catholic, 2·6 Evangelical, 2·98 Jewish, other faiths 0·3%.

Education.—At the end of 1918 there were 4,102 free public primary schools (*Volksschulen*), with 17,497 teachers and 788,891 pupils; 331 higher elementary middle-class schools (*Bürgerschulen*), with 3,310 teachers and 82,739 pupils; 362 private lower elementary schools with 35,511 pupils; and 69 private higher elementary schools with 6,114 pupils; 1,875 teachers served these private schools. In 1910 the average proportion of persons over 10 years of age who could both read and write was 95·70% (in Vorarlberg 99·12%, in Carinthia 85·43%); 0·80% (in Carinthia 2·28%) could only read and 3·5% could neither read nor write. At the end of 1918 there were 37 institutions for training teachers—16 for men and 21 for women. In addition to the elementary schools there are three groups of higher schools: intermediate schools, professional and technical schools, and "high" schools. There are also higher and lower schools for forestry and agriculture. In 1917-8, 46 of the intermediate schools (*Mittelschulen*) were *Gymnasien* (classical schools), 26 *Realgymnasien, Reform Realgymnasien*, etc. (in which Latin is taught); 39 *Realschulen* (modern, without Latin) and 26 *Madchenlyzeen* (girls' colleges) with, together, 3,135 teachers and 40,147 pupils. Of the girls' colleges, one ranked as a *Gymnasium* and two as *Realgymnasien*. But girls are required to attend the other intermediate schools; the number of girls' colleges is diminishing. The churches have charge of religious instruction in the elementary and intermediate schools. In 1917-8, there were 9 higher and 32 second-class commercial schools, 19 higher technical schools and 53 special technical schools; and 4 intermediate and 38 lower agricultural and forestry schools.

The higher educational establishments are:—Three universities (Vienna, Graz and Innsbruck), each with four faculties—Catholic theological, law and political sciences, medicine, and philosophy; two technical colleges (Vienna and Graz); the Evangelical theological faculty in Vienna, and that of Catholic theology in Salzburg. There are also in Vienna the high schools of commerce, agriculture and veterinary science, the consular academy, the academy of plastic arts, the special school for medal and stamp engraving, the academy of music and graphic arts, and at Leoben the college of mining.

Agriculture and Forestry.—In the returns according to occupations taken in 1910, it appeared that 40·14% of the population was engaged in agriculture and forestry, 34·81% in manufacture, 17·40% in trade, and 7·65% in other occupations. Not taking Vienna into account, 56·36% was engaged in agriculture and forestry. In 1900, 10·4% of the land was unproductive (in Tirol 23·7%; in Lower Austria 3·7%).

Of the productive areas, 25·6% was arable (in Lower Austria 45·2% and in Vorarlberg 3·4%), 1·7% gardens and vineyards (in Lower Austria 3·5% and in Vorarlberg 0·2%), 12·4% meadow (in Upper Austria 20·1% and in Tirol 7·4%), 17·8% grazing-lands (Vorarlberg 51·3% and Upper Austria 2·7%), 42·5% forest (Styria 54·4% and Vorarlberg 29·4%). The high Alpine lands of Vorarlberg, Tirol and Salzburg are characterized by the smallness of their total

cultivated area and their large expanse of pasturage, and the country of the Danube valley by its large area of arable and small amount of meadow-land. The territories of Styria and Carinthia have an intermediate character, being mostly thickly wooded.

The chief crops are rye, oats, barley, potatoes, maize, pulse, turnips and flax; but the supply falls far short of the demand. In 1913 3·5% of the arable land lay fallow, and in 1918 no less than 17·5%. Fruit-growing is wide-spread, but vine-culture has attained importance in Lower Austria only. The timber output, on the other hand, is very important, the forests in 1910 covering 11,912 sq. m., of which 8,576 were covered with pine forest and 926 with deciduous trees only. Stock-raising is important in many districts, but in 1921 by no means met demands. Excellent breeds of cattle are reared in Vorarlberg (Muntafun breed), Tirol (Tuxertal, Pustertal, etc., breeds), Carinthia and Styria (Noric Alpine breed). In 1918, there were 1,841,883 head of cattle (of which 901,894 were milch-cows) and 1,269,875 swine. Good breeds of horses are raised, especially in Salzburg (Pinzgau breed), but the total number scarcely reached 200,000. There were some 300,000 sheep and a slightly smaller number of goats. Poultry abounds (some six million head in 1918). Bee-culture thrives in Carinthia and Styria in combination with the cultivation of buckwheat.

Minerals.—The mining output of 1915 included some 75,000 tons of coal (almost all from Lower Austria), 2·4 million tons of brown coal (1·8 from Styria), 1·8 million tons of iron ore (almost all from Styria), 17,000 tons of copper ore (almost all from Salzburg), 12,500 tons of lead ore (almost all from Carinthia), 14,000 tons of graphite (almost all from Styria), considerable quantities of magnesite (from Styria and Lower Austria), some sulphur and ores of zinc and antimony, and (from Styria) bitumen. The output of salt was 160,000 tons; of which 100,000 tons were produced in Upper Austria, the remainder in Styria, Salzburg and Tirol. Natural gas is obtained at Wels in Upper Austria.

The most important mines are:—The iron mines in the Styrian Erzberg (Eisenerz and Vordernberg) and those of Hüttenberg in Carinthia; the copper mines of Mitterberg in Salzburg; the lead mines of Bleiberg in Carinthia; and the brown-coal mines of Köflach and Voitsberg, Wies and Eibiswald, Fohnsdorf and Leoben, in Styria, Wulfsegg in Upper Austria. The salt mines have already been mentioned. The smelting industries produced 500,000 tons of pig iron (almost exclusively in Styria), some 5,000 tons of copper (in Salzburg), about 8,000 tons of lead (in Carinthia), besides copper sulphate, mineral colours, a little silver and a very little gold. The output decreased after 1915 but was recovering in 1921. With the exception of iron ore and magnesite, the minerals do not suffice to meet the needs of Austria herself; she can only supply one-seventh part of the coal she requires.

Manufactures.—The industries of Vienna are very varied. Industrial areas of the first rank are:—Lower Austria, Vorarlberg and Upper Styria; next to them come Upper Austria and Middle Styria. The largest iron works are in Styria (Eisenberg, Vordernberg, Hieflau, Donawitz, Zeltweg, Kapfenberg, Mürzzuschlag); in Lower Austria (Waidhofen an der Ybbs); in Upper Austria (Linz, Wels). There are also machine factories in the above territories, especially in the neighbourhood of Vienna. Iron smallware, such as scythes and sickles, is chiefly made in the districts along the border between Upper and Lower Austria and Styria; Steyr is an important centre. Locomotives are made in Vienna, Wiener Neustadt, Graz and elsewhere; small arms in Steyr, Vienna and Ferlach; carriages and automobiles in Vienna and Graz; bicycles at Steyr and Graz; river boats at Linz. Lower Austria (Berndorf and elsewhere) is noted for the manufacture of base metal goods. Carinthia produces leaden articles.

The cotton and woollen industries are important, especially in the Vienna district, Vorarlberg and near Linz and Graz. Important, also, are the jute industry of Lower Austria and the manufactures of machine-made knitted goods in Vorarlberg. The coarser kinds of woollen cloth are made in Tirol and Vorarlberg; clothing, silk goods and articles of luxury of all kinds are made in Vienna, hats in Vienna and Graz. Vienna is also noted for the manufacture of furniture. The wood, cellulose, pasteboard and paper, and paper-goods industries of Lower Austria, Styria and Upper Austria are very important. Leather and leather goods are chiefly produced in Lower Austria; shoes and gloves in Vienna. The Vienna district and the foot-hills of the Alps are flour-milling centres, while distilling and malting are chiefly carried out in Vienna. The chemical industry is notably active in Vienna and its neighbourhood; also the manufacture of colours and varnishes. The manufacture of explosives is centred in Middle Styria (Deutsch-Landsberg), and there are chemical works in the Alps, when water-power is available. The pottery and glass-making industries are also noteworthy. Vienna is the chief centre of printing and the graphic arts, and of artistic trades generally.

The manufacture of tobacco is a State monopoly (there are factories in Vienna, Hainburg, Fürstenfeld and other places). (R. Si.)

Constitution and Administration

The collapse of the Austrian Empire in the autumn of 1918 was an event which all nationalities living within its frontiers anticipated. They were thus prepared, sooner or later, to set themselves up as independent states. Serious resistance was not to be expected, as the military *débâcle* had been so complete as to prevent any possibility of stopping the process of disintegration. A premonitory symptom had been the Imperial Manifesto of Oct. 16 1918, in which the Emperor Charles announced his resolve, in accordance with the wish of his peoples, to transform Austria into a Federal State in which every nationality was to form a separate state-entity within its own ethnographical limits. Not many years previously such a manifesto might have initiated a happy development by which the World War would have been avoided and Austria perhaps been consolidated. But now it was too late, and the manifesto was thus no more than a signal given in the highest quarters of the approaching general dissolution.

Independently of the Imperial Manifesto, and by a procedure purely revolutionary, the German members of the former Austrian Reichsrat, on Oct. 21 1918, established themselves as the Provisional National Assembly of German-Austria, and as such established the new state of "German-Austria," for which a provisional constitution was adopted on Oct. 30. The new constitution, which was republican, was carried at once, and without the least resistance being encountered, though it was not till Nov. 11 that the Emperor Charles issued a proclamation, countersigned by his last prime minister, Lammasch, in which he declared himself ready to acknowledge beforehand whatever decision German-Austria might come to concerning her future constitution, and renounced all share in affairs of State. The revolution out of which the new German-Austria emerged was thus not only bloodless, but was carried through without any open struggle. It was, none the less, a revolution; for the constitution of German-Austria was not evolved by any legal process out of the constitution of old Austria. Between the two lies the break in the continuity of constitutional practice, and it is for this reason that German-Austria cannot, any more than Czechoslovakia, be looked upon as identical with the old Austria.

The Provisional Constitution.—The first provisional constitution of German-Austria, created by the resolution of Oct. 30 1918 and supplemented by several later laws (above all, that of Nov. 14 1918 on the taking-over of State authority in the Territories, and that of Nov. 19 1918), exhibits an extreme type of democratic parliamentary government. The supreme power in the State, executive as well as legislative, was conferred upon the Provisional National Assembly. This exercised its legislative power directly through its enactments. Its executive power, however, was exercised through a Council of State (*Staatsrat*) elected from among its members, the three parliamentary parties—Christian Socialists, Social Democrats and German Nationalists—being proportionally represented. The Council of State thus formed a parliamentary committee which functioned as a sort of head of the State.

In contradistinction to the old Austrian Reichsrat, with its Upper and Lower House, the first legislative body of German-Austria was organized on the single-chamber system. Each of the three parties elected a president to act as speaker of the parliament. These three presidents were coequal and occupied the chair week by week in an agreed rotation.

The legislative power of the Provisional National Assembly was restricted, in that legislation on certain matters, which under the old system appertained to the autonomy of the so-called Crown Territories (*Kronländer*) of the Austrian Empire, was reserved for the Provisional Territorial Assemblies, which had taken the place of the former Territorial Diets (*Landtage*) in which the functions of self-government had been vested. For these, under the style of "Territories" (*Länder*), remained within their old frontiers—though, of course, only to the extent in which they formed part of the new State: viz. Lower and Upper Austria, Salzburg and Vorarlberg, in their entirety; Styria and Carinthia, with the exception of areas inhabited by Yugoslavs; Tirol, without its southern part mainly inhabited by Italians. Out of the former "crown lands," Bohemia,

Moravia and Silesia, which were inhabited by about 3½ million Germans, two new Territories were carved: German-Bohemia and Sudetenland, each with a Provisional Territorial Assembly. In actual practice, however, the executive power of German-Austria could not extend to these Territories, as they were held by the Czechoslovak State, to which they were eventually assigned. As the revolutionary constitution of the Territorial Assemblies and of the Territories themselves took place at the same time as that of the National Assembly and of the State, but independently, the limits between Territorial legislation and State legislation were not clearly defined from the very outset. The Territories became the centres of a movement in favour of an extreme form of federalism, and this led to the constitution of Austria being ultimately that of a Federal State.

A State law required essentially only a resolution of the National Assembly, which had to be registered and attested by the Council of State and published in the Government law gazette.

The Council of State had a suspensive veto on legislation, but this was overridden by the simple passage of a measure a second time through the National Assembly, a bill then passed at once becoming law. According to the constitution a Territorial law to be valid required not only to be passed by the Territorial Diet but to receive the assent of the Council of State, which, in this as in other respects, had taken the place occupied by the Emperor under the old Austrian constitution. In view of the actual power of the Territories, however, the Council of State was unable to assert its right of veto.

Apart from the 20 delegates, and an equal number of substitutes, elected as already described, the Council of State included the three presidents of the National Assembly, who presided over it in rotation. Though the Council, thus constituted, was the supreme organ of parliamentary Government, it did not itself carry on the administration directly, but through a Cabinet, nominated by it, consisting of so-called secretaries of State, who acted as heads of departments. The Cabinet was also to be presided over by the presidents of the National Assembly in rotation, and it was only in the absence of these that the State Chancellor, whose functions were in fact those of minister-president, took the chair. The Cabinet was subject to the principle of ministerial responsibility, which could be enforced in the special court for dealing with infringements of the laws and constitution (*Staatsgerichtshof*), the functions of which had originally been transferred to a parliamentary committee of twenty.

The whole machinery of administration was taken over from the old Austria almost without a change. Only in the case of the offices forming an intermediate link between the administrations of the Territories and the State was there any drastic reform. Each one of the so-called "Crown Territories" (*Kronländer*), of which the Austrian monarchy was composed, constituted the area of an intermediate administration, at the head of which was a governor or lieutenant (*Statthalter*) nominated by the Emperor and subordinate to the central Government. Side by side with this, however, the Territories existed as autonomous bodies politic, with an administrative system of their own in all matters not falling within the province of the central administration. This autonomous administration was exercised by the Territorial Diet (*Landtag*) through a Territorial Committee (*Landesausschuss*) elected from among its members and presided over by the president of the Diet, who was nominated by the Emperor.

This parallelism of the autonomous and State administrations in the Territories, with the rivalry between them, had been one of the worst evils of the old monarchy; it was done away with under the provisional constitution of German-Austria by the simultaneous democratization of the intermediate administrative system. The whole administration in the Territories was declared to be a State concern; the autonomous and State administrative organizations were amalgamated and subordinated to a Territorial Government, consisting of the head of the Territory (*Landeshauptmann*) and several substitutes elected by the Territorial Assembly from among its own members. This Territorial Government was subordinated to the central State Government in all matters of Territorial administration, but there were no legal provisions for making this subordination effective. The central State Government could not depose a Territorial Government, nor could it in any way call it to account for disobedience; it was, in short, wholly dependent on the goodwill of the Territorial Government, which, since it was elected by the Territorial Diet, felt itself politically responsible to this alone. This led to a very serious loosening, almost indeed to the complete dissolution, of the administrative system of the State, and was one of the factors which ultimately led to the adoption of the Federal constitution.

As regards the organization of justice and the relations of the citizen to the State, the new provisional constitution confined itself to adopting, more or less unaltered, the respective rules of the old Austrian constitution. In the same way all the remaining private and public law of the monarchy, in so far as it was not inconsistent with the new constitution, was expressly taken over under an article of the provisional constitution, and thus, formally at least, given a fresh validity.

The main task of the Provisional National Assembly, in addition to the creation of a provisional constitution, was to prepare the way for the Constituent Assembly, for which the framing of a definitive constitution was reserved. According to the electoral law passed by the Provisional Assembly, the Constituent Assembly was to consist of 225 members, who were to be elected in 38 constituencies on the basis of equal, secret and personal suffrage for all citizens at least 20 years of age, without distinction of sex, and on the system of proportional representation. Actually, however, only 170 members were returned, as no elections could be held in the territories occupied by Czechoslovakia, Italy and Yugoslavia. Of the 170 deputies, 72 were Social Democrats, 69 Christian Socialists, 26 German Nationalists, the three remaining being a Bourgeois-Democrat, a Czechoslovak, and a Jewish Nationalist (the two latter having supporters in Vienna only).

The Constituent Assembly.—The Constituent National Assembly met at Vienna on March 4 1919. Before settling the definitive constitution it made one or two not unimportant modifications in the provisional constitution (laws of March 4 on Popular Representation and the State Government). Above all, the relation between State and Territorial legislation was regulated. In the first place it was decided that all legislative acts of the Territorial Diets were to be submitted to the central State Government, to which was assigned the power of suspensive veto and, in the event of such acts being contrary to the constitution, the right to challenge them before the court established to try constitutional cases (*Verfassungsgerichtshof*). Acts of the Territorial Diet needing the coöperation of the central Government for their execution were made subject to the endorsement of the latter. Drastic alterations were made in the organization of the executive power. The Council of State, with its directory, was abolished, and its governmental and executive powers transferred to the Cabinet, which was henceforth to be directly elected by the National Assembly. The election of the Cabinet was entrusted to the Principal Committee (*Hauptausschuss*), itself elected from the body of the Parliament, the three chief parties being proportionally represented. This Committee, through which Parliament exercised a decisive influence over the executive and without whose consent no important act of Government could be undertaken, to a certain extent took the place of the Council of State, but, unlike this, without any public appearance of functioning as the head of the State. These functions—representation of the State in its relation with foreign Powers, more especially the ratification of treaties, the nomination of officials, the right of pardon, etc.—were entrusted to the president of the National Assembly; so that in this way, too, the character of parliamentary Government found outward expression.

The conclusion of the Treaty of St. Germain compelled a further alteration of the constitution of German-Austria. By

the law of Oct. 1 1919 (on the form of the State) the frontiers of the State were legally defined in accordance with the provisions of the treaty, *i.e.* the Territories assigned to the other "succession states" were cut off. In these Territories there lived, in a solid group, nearly half as many Germans as the treaty had left to German-Austria, now sadly diminished. The name of the State, which had hitherto been German-Austria (*Deutschösterreich*), was legally altered to "the Republic of Austria" (*Republik Oesterreich*), for it was only under this name that German-Austria could obtain international recognition. The sentence "German-Austria is a constituent part of the German Reich," which had hitherto been embodied in the constitution but had represented an aspiration rather than a fact, was now excised, in accordance with Art. 88 of the Treaty of St. Germain, which decreed the "independence" of German-Austria.

Of the remaining provisions of the treaty affecting the constitution of German-Austria, attention need only be called to those dealing with the protection of minorities, which did not, however, add anything essential to the safeguards for nationality and creed secured by the old Austrian fundamental law of Dec. 21 1867 on the general rights of citizens of the State, which had been adopted in the German-Austrian constitution.

The Federal Constitution.—It was only under the greatest possible political difficulties that the Constituent Assembly could be brought to fulfil its proper function, that of framing a definitive constitution. From the very first the Federal character of this constitution was above all determined by the fact that this was the only possible way of overcoming the ever-increasing tension between the Territories and the State as a whole. Moreover, the provisional constitution had already contained certain Federal elements, and these had now to be developed in order to give the Territories, constitutionally as well as in fact, the position which they claimed.

From the point of view of technical organization a Federal State may exhibit one of two types of character. In one the legislative and executive power may be divided between a central legislature and executive, whose activity constitutionally covers the whole State, and a number of local legislatures and executives, with jurisdiction over territorial subdivisions of the State, which are known as subordinate states. In the other, the legislatures and executives of the subordinate states may share the legislative and executive powers of the organs of the central State. The first of these types was already exhibited in the provisional constitution of German-Austria. To make the constitution of the Federal State complete, the Austrian Republic really only needed to give the subordinate states, *i.e.* the so-called Territories (*Länder*), a share in the legislative and executive powers of the central organs of the federation or super-state. The federal constitution created by the law of Oct. 1 1920, however, was not confined to completing the provisional constitution by adding provisions to this effect; it was an effort at a complete reconstruction of the State, in which an attempt was made to balance the strengthening of the federalistic elements by an equivalent elaboration of a centralized legal jurisdiction over legislative and executive acts.

The division of legislative and executive functions between the super-state, known as the Federation (*Bund*), and the subordinate states, known as Territories (*Länder*), resulted in the classification of affairs into four groups. With regard to the first group, which embraced the most important functions of the State—*e.g.* civil and criminal law, jurisdiction, foreign relations, etc.—legislative and executive powers are reserved wholly to the Federation, the Territories being completely excluded. In the case of the second group, the Federation alone has the power to make laws, but their execution is the affair of the Territories. In the case of the third group, the Federation has the power of legislation in so far as it may lay down general principles, but it is for the Territories to give these principles practical effect in laws and to see to their execution. All matters which do not fall under one or other of these groups constitute the fourth group, which is wholly within the legislative and executive province of the Territories.

The legislative organ of the Federation is the National Council (*Nationalrat*), of which the composition is the same as that of the National Assembly under the provisional constitution, and the Federal Council (*Bundesrat*). In the Federal Council the individual Territories are represented in proportion to the number of citizens customarily domiciled in them, a principle differing from that of Switzerland and the United States, where, in the *Staatenhaus* and Senate respectively, the subordinate states have an equal voice whatever their size, but approximating to the constitution of the German Reich, under which the subordinate states were from the first represented in the *Bundesrat*, as later in the *Reichsrat*, according to their size. According to the Austrian constitution, however, the representation of the Territories in the *Bundesrat* is by no means strictly proportional. The largest Territory sends 12 representatives, the rest in proportion to the number of their citizens; but no Territory sends less than three representatives, although the three smallest Territories—Tirol, Salzburg and Carinthia—would not be entitled to so many were the principle of proportional representation strictly carried out. In order to correct the disproportion between Lower Austria, with its population of some 3,000,000, and the smaller Territories, whose population does not exceed 140,000 and 400,000, the Territory of Lower Austria was divided into two parts—the Federal capital, Vienna, and the Territory of Lower Austria. Vienna, with its 1,800,000 inhabitants, is the largest subordinate state.

As the Federal Council is fundamentally concerned only with legislation, and only in very exceptional cases with executive affairs, its members are deputed not by the Governments of the Territories but by the legislative bodies, which are again styled *Landtage* (Territorial Diets), and they are elected on the system of proportional representation. As a legislative organ the Federal Council is in no way placed on an equality with the National Council; it has a suspensive veto, but if the National Council again passes a bill thus vetoed, it becomes law *ipso facto*. A further alteration of the legislative machinery established by the provisional constitution was the introduction of the constitutional referendum and of the right of popular initiative.

The executive power of the Federation is exercised by the Federal Government, whose members are called Federal ministers and meet under the presidency of the Federal chancellor or vice-chancellor; they are assisted in their several departments by secretaries of State. The Cabinet is composed in the same way as under the provisional constitution—election by the National Council on the recommendation of the Principal Committee. An important alteration in the provisional constitution was that the executive functions hitherto assigned to the president of the National Assembly were transferred to a special head of the State, the Federal president, elected for one year by the National Council and Federal Council meeting in joint session under the name of Federal Assembly. To this Federal Assembly the president is responsible.

The executive powers of the Federation are exercised in the Territories by Federal organs subordinated to the Federal Government, or, as a general rule, by the organs of the Territorial Government in the sphere of activity devolved upon them. In the latter case the Territories function as organs of the Federation and are subordinate to it. For this reason the Federation is interested in the constitutions of the Territories, and the Federal constitution therefore contains far-reaching provisions as to the organization of the Territories, and it is only within the limits of these provisions that the Territories are free to settle their own constitutions. So far as their legislatures are concerned, the Federal constitution prescribes the single-chamber system for the Diets, as now established, and their election on the same franchise basis as the National Council. The Territorial Government is to be elected by the Diet, and is to consist of the *Landeshauptmann* and a number of other members. In respect of the spheres of Federal activity assigned to the Territories by devolution from the Federal Government—that is to say, those in which the Territories act as the organs of this Government—it is the *Landeshauptmann* and his subordinates

who are alone concerned. In such cases the ultimate administrative authority is held to lie with the Federal Government, to which the *Landeshauptmann* is responsible. The Federal Government is now in a position to enforce this responsibility by prosecution in the court established to try constitutional offences (*Verfassungsgerichtshof*). The Federal Government also has an influence on legislation in the Territories. It is true that it can only exercise a suspensive veto over enactments of the Territorial Diets, which have all to be submitted to it; but in cases where Federal coöperation is needed in the execution of such enactments, these may not be made public without its consent. In the case of enactments, already published, which are contrary to the constitution the Federal Government has in reserve the possibility of challenging them in the Constitutional Court.

The weightiest influence of the Federal constitution is exercised through the special courts of law established under it to decide cases of alleged violation of the constitution in matters of administration or legislation. Anyone whose rights have been violated by an illegal decision or act of the Federal or Territorial authorities, and who has failed to obtain redress through the ordinary administrative channels, can appeal to the court for the trial of administrative cases (*Verwaltungsgerichtshof*). This court has power to pronounce on the legality of such decisions or acts, and in certain circumstances to amend them. The members of the court, like all the Federal organs, are nominated by the president on the recommendation of the Federal Government, but this recommendation needs, in respect of half the members, the consent of the Principal Committee of the National Council and, in respect of the other half, that of the Federal Council.

The second court administering public law is the Constitutional Court (*Verfassungsgerichtshof*). Of this the president and vice-president, as well as half the members, are elected by the National Council, the other half by the Federal Council. Its primary function is to decide disputes between authorities as to their competence. As the State Court it furthermore hears charges brought by the National Council against Federal ministers, by the Federal Assembly against the Federal president, by the Diets against members of the Territorial Governments. As a court of ordinance (*Verordnungsgerichtshof*) it judges cases of illegal decrees appealed at the instance of the Federal courts or of those of the Territories. Lastly, as a constitutional court in the narrowest sense, it decides, at the instance of the Federal or the Territorial Governments, whether Federal or Territorial laws are or are not constitutional. It has the right to quash an illegal decree or an unconstitutional law. The Constitutional Court also acts as the central court for hearing petitions against elections to all bodies elected by the general vote. It also judges in cases of violation of international law.

The law of the Federal constitution of Oct. 1 1920 did not complete the new structure of the Austrian constitution. Several special laws were still needed, aiming more especially at the reform of the administration both in the Federation and in the Territories. It was hoped that, in the spirit of democratic self-government, this administrative reform would follow the lines of local government in England.

Authorities.—See Kelsen, *Die Verfassungsgesetze der Republik Oesterreich* (1919), and *Die Verfassung Deutschoesterreichs* (*Jahrbuch des öffentlichen Rechts*, vol. 9, 1920); Merkl, *Die Verfassung der Republik Deutschoesterreich* (*Zeitschrift für öffentliches Recht*, vols. 1 and 2, 1920). (H. K.)

Finance and Banking.—When in the last days of Oct. 1918 the various parts of the Austro-Hungarian monarchy constituted themselves on one side independent states (the Austrian Republic, the Czechoslovakian Republic, Hungary, and the republic of West-Ukraine), and for the other part decided on joining already established nations (Italy, Rumania, Yugoslavia), or joined territories detached from other states and forming new states (Poland), there existed in all these territories one uniform paper currency in circulation, *i.e.* the notes of the Austro-Hungarian Bank, enjoying a fixed rate. It was clear that such conditions could not be maintained for any length of time, and that, in view of the connexion between paper money of fixed rate and State finance, it was impossible to continue this unity of currency. All the states concerned, which succeeded the Austro-Hungarian Monarchy, were in such financial straits that they considered the continued recourse to the issue of notes a necessity. The note-printing press, however, was in Vienna, and the Austro-Hungarian Bank was actually under the deciding influence of the new German-Austrian Government. It was urgently necessary for the new states to obtain an independent currency, *i.e.* to make themselves independent, so far as the printing of notes was concerned, of the Vienna note-printing press. This was comparatively easy for those who had joined already existing states, but more difficult for the newly formed states which were obliged in the first instance to create a new currency. In these conditions the money problem, at the moment of the dissolution of the Austro-Hungarian Monarchy, was merely a technical problem of printing, and the question how to obtain printing-plates, banknote-paper and printing-ink appeared for the moment the most important points of currency policy. After the Italian Government as early as Nov. 1918 and the Rumanian Government in Feb. 1919 had made the necessary preparations to substitute respectively the *lira* and the *lei* for the Austro-Hungarian "*krone*," in the territories occupied by them, the Government of the Serbo-Croatian-Slovenian State proceeded in Jan. 1919 to mark the Austro-Hungarian notes circulating within their territory by stamping them. On Feb. 25 1919 the Czechoslovakian Government followed suit by stamping the *kronen* notes circulating in their country. Then the Austrian Government could not remain idle. It could not wait until all the other states had passed from the Austro-Hungarian *krone* to a national *krone*. It had to get rid of the Austro-Hungarian *krone*, in order to avoid the danger of such notes as for one reason or another had not been stamped by the other states returning to German-Austria and there increasing the inflation. The *kronen* notes circulating in German-Austria were therefore also specially marked, and, by a regulation of March 25 1919 having the force of law, it was decreed that all notes not so marked would not be legal tender within the German-Austrian State.

A decree of Feb. 27 1919 had ordered the stamping over of all notes of the Austro-Hungarian Bank circulating within the territory of the German-Austrian Republic, with the exception of the notes for one and two *kronen* (which also subsequently were ordered to be stamped). With the execution of this regulation the German-Austrian currency was separated from that of the other "succession states," and there was only one special *kronen* note, which was stamped as recognized legal tender for Austria.

The German-Austrian Republic also used the note-printing press as its chief expedient for covering the national expenses. At the time of the carrying-out of the stamping process, at the end of June 1919, the stamped German-Austrian notes in circulation amounted to 7·6 milliards of *kronen*; at the end of 1920 the circulation had risen to 30 milliards. In consequence there was a further depreciation in the exchange. On Dec. 31 1920 the dollar was quoted in Vienna at 668 *kronen*, as compared to 5 *kronen* in pre-war times.

The republic of Austria at first not only maintained the system of restricting exchange operations, introduced under the Empire during the war, but even made it more severe. Only in the summer of 1920 was any relaxation permitted, in so far as the forced release of foreign currencies obtained for goods exported was generally cancelled. In Nov. 1920 further modifications were made, so that by the end of 1920 the only restriction of money transactions with foreign countries remaining in force was the prohibition to import or export *kronen* notes. The regular exchange operations on the Vienna Bourse were, however, not revived. They were replaced by a system of restricted exchange business under the special supervision of the still existing *Devisenzentrale*.

The general political conditions and the depreciation of money had led to such an *impasse* that up to 1921 the whole financial

system of the republic was in a state of uncertainty. On the one hand, the Austrian State, by the peace treaty of St. Germain, was made liable toward foreign countries for an amount not specifically determined. On the other, it was found necessary for political reasons to introduce a system of providing the population with cheap victuals. As these had to be obtained almost exclusively against payment in foreign currency abroad, and it was desired to sell at home at the lowest possible prices, there resulted a considerable discrepancy between the expenses necessitated by this part of the State budget and the income derived. At the beginning of 1921 the deficit of the Austrian budget was estimated at hardly less than 50 milliards of *kronen* per annum. To cover this deficit the Austrian State, with the help of the Allied Powers, contracted loans abroad, and for the rest relied on the note-printing press. Only a small part of the expenses of the State could be covered by taxation, notwithstanding that all direct taxes were greatly increased and a new direct tax, an extraordinary property tax, was specially introduced in 1920. Of this property tax, the fixing of which required enormous preparation, it was permitted to make prepayments in Feb. 1920 under specially favourable conditions. Such prepayments brought in over 7 milliards of *kronen*, but more than half of these prepayments were made in war loan. The situation of the Austrian State budget was therefore in 1921 a most unfavourable one. An improvement could only be expected on the one hand by doing away with the system, which could not be permanently maintained, of providing necessaries for the population below cost price at the expense of the State, and on the other by a radical reform of the many State and municipal enterprises (post, telegraph, telephone, State railways, salt-mines, tobacco manufactories, town railways, illumination and power works). (L. v. M.)

History

When in Oct. 1918 the break-up of Austria-Hungary became a matter of common knowledge (*see* Austrian Empire), the Germans of Austria also announced their right to self-determination. The impulse towards this movement came from the left wing of the Social Democrats who occupied the same standpoint as the Independent Socialists of the German Reich. They had long opposed the view that the dissolution of the Habsburg Monarchy, which was not highly industrialized, and the annexation to a strongly socialistic Germany of the Austrian territories with a German population (the Alpine territories, German Bohemia, and the Sudetic territories), which would thereby be rendered possible, must necessarily involve a proletarian policy; and their views now completely gained the upper hand over the Great Austrian tendencies within the party. The "provisional National Assembly" of German-Austria at its first session (Oct. 21 1918) did indeed regard its connexion with the other national states of the old empire as not yet fully dissolved. But only nine days later (Oct. 30 1918) the new State was constituted in the fullest independence of the dynasty and of its former companion states speaking other languages. The last impulse towards this radical procedure had been given by Andrassy's overtures for a separate peace, which were regarded in wide circles in German-Austria as a betrayal by the Emperor of the German people, and gave rise to revolutionary demonstrations in Vienna. Under the influence of subsequent events in Germany the Emperor Charles was compelled to renounce, on Nov. 11 1918, the exercise of governmental functions, and henceforward to recognize whatever form of government the people might choose. The day after, under pressure from the Social Democrats, the republic was proclaimed.

In the new free State all three parties—the Christian Socialists, German National party, and Social Democrats—formally assumed a share of the responsibility of government. Thus from the outset power had passed almost entirely into the hands of the Social Democrats. The bourgeois parties acquiesced all the more willingly in this, since they were of opinion that only the Labour party would be able to conjure away the dangers which threatened from the break-up of the old army and of the old authorities. The Social Democrats piloted the State skilfully through the first great vicissitude, though naturally in accordance with their own point of view. Above all, in order to check any reactionary tendencies, they disbanded all bodies of troops belonging to the old army on their return from the front, and placed the newly formed militia (*Volkswehr*), manned by the proletarian classes, under the leadership of councils of soldiers who were faithfully devoted to them.

But the very first two months cost the young republic serious losses of the territorial possessions which they had claimed on the basis of the "right of self-determination." The Czechs occupied not only all the Sudetic territories populated by Germans, but also a few strips of land on the borders of Lower Austria. The Yugoslavs, going beyond the Slovene territories of Southern Styria, stretched out their hands towards the purely German towns of Marburg and Radkersburg. The repeated attempts which they made early in 1919 to gain a footing also in German portions of Carinthia were repulsed by the inhabitants, accustomed as they were to war. From the beginning of the Armistice German Southern Tirol—with Botzen and Meran—found itself in Italian hands.

The "Constituent Assembly" was elected under the influence of the terrible economic consequences of the war and of the break-up of the monarchy. The Social Democrats won a "relative" majority, with 72 seats out of 170. They formed a coalition for purposes of government with the second strongest party, the Christian Socialists, who represented the peasant and lower middle-class elements. At the head of the Cabinet was the State Chancellor, Dr. Karl Renner, who had already directed the Government since the revolution. The secretaryships of State, which were of more political importance, were likewise occupied by Social Democrats, who also set the pace in other departments. Otto Bauer, who was followed in the Ministry for Foreign Affairs as early as 1918 by Victor Adler, strove with all his strength for a union of German-Austria with the German Reich, in which endeavours he was supported by all but a section of the Christian Socialists. The preliminary negotiations conducted with Berlin early in 1919 met with a favourable result. Bauer counted very much in his plans upon the support of the Italians, to whom the Austrian policy of union might be welcome for a variety of reasons. As to internal policy, the object was to make the republican form of government lastingly secure. The National Assembly set aside the dynasty of Habsburg-Lorraine, banished its members from the country if they did not submit entirely to the laws of the republic, confiscated a great part of its family domains, and abolished the nobility. The leading party was particularly zealous in introducing numerous laws of a socialist nature, of which the early part of 1919 was especially productive.

The alarming conditions of Austria came daily more darkly into view. Famine and misery forced the State straight into the abyss of serious social shocks. Soldiers and civilians, professionals and amateurs, seized at the means of self-protection. The several Territories (*Länder*), in all of whose Diets—with the exception of Lower Austria—Christian Socialist majorities had been sitting since the elections in the summer of 1919, put up political and economic barriers against each other, and sealed themselves off even more hermetically from Vienna. Both in town and country party organizations of every sort interfered in administration—generally with the best intentions—and this resulted not infrequently in attacks on the freedom and property of their fellow citizens. The State Government was meanwhile powerless. The events in Budapest and Munich, where, in March and April 1919 respectively, Soviet republics had been set up, prompted to action the small Austrian Communist party, which had seceded from the Socialists of the Radical Left during the days of the revolution. In Vienna, on Easter Thursday and on June 6 1919, excesses were committed in consequence of the plots of native and foreign Communists, which led on both occasions to loss of life. If more serious consequences were avoided, this was as much due to the admirable police of Vienna as to the quiet and reasonable attitude of the Socialist leaders,

who were conscious of their responsibility, and the good temper of the German-Austrian populace. When it became clear that the Communist disturbances were to no small extent fomented by the Hungarian Mission in Austria, dissensions arose between Vienna and Budapest, which were not settled till the Hungarian Soviets replaced their envoy, who had been involved in the affair, by a *persona grata*.

On May 12 1919 the State Chancellor, Dr. Renner, had gone with a delegation to St. Germain-en-Laye to receive the terms of the dictated peace. With the exception of the Magyars, all the countries formerly under the same Government as the German-Austrians had "associated" themselves with their enemies in the World War. It was in no small degree due to their counsels that the Treaty of Peace turned out to be even more severe than that with Germany. In comparison with the loss of former German territory and of 3,000,000 German-Austrian subjects, combined with unprecedentedly heavy economic burdens and restrictions, the acquisition of the Burgenland (German Western Hungary) and the promise of the Entente to assist in the reconstruction of Austria seemed but poor advantages, the value of which remained to be proved.

Otto Bauer recognized in the provisions of Article 88, which specifically forbade Austria's union with Germany, and in the fact that Italy, in spite of the Italophil attitude of the Vienna Cabinet, annexed German Southern Tirol for good, a complete defeat for his policy; and he resigned. Renner took over in person the charge of foreign affairs. The Treaty of St. Germain was signed on Sept. 20 1919, with a few small modifications of the original draft; on Oct. 17 it was approved by the Constituent Assembly; and in July 1920 it came into force. By his open adhesion to "Westernism" and the policy of the League of Nations, Renner made known Austria's honourable intention of taking her stand entirely on the basis of the Peace Treaty, in which case she hoped for help from the Entente in her destitution, which had been made even deeper by the operation of the Treaty. In Dec. 1919 the Chancellor found an opportunity of making personal representations in Paris as to the sufferings of his country; in Feb. 1920 other Austrian statesmen were in a position to do the same. Indeed, on more than one occasion Austria received temporary assistance. Moreover, the general right of the Entente to a mortgage on all Austria's assets, provided for in the Peace Treaty, was so far limited as to facilitate the acquisition from abroad of those commodities which were most pressingly necessary for the moment. A special "Austrian Section of the Reparations Commission" was appointed to study the measures most necessary for a lasting cure for the ills of the body politic, and met in Vienna on April 17 1920 under the presidency of Sir William Goode. The international commissions which were to supervise the disarming of Austria by land, water and air, also came into operation. And thus Austria's sovereignty no longer existed except in appearance.

Renner's first Coalition Cabinet was followed in Oct. 1919 by a second one composed of the same parties. It had also the task of establishing normal relations with the neighbouring states. The visit made by the Chancellor to Rome in April 1920 on the invitation of Italy—on which occasion he was also received at the Vatican—was a not unfavourable introduction to these efforts. Among the "succession states" it was chiefly Czechoslovakia to which the Social Democratic party, which was as influential as ever, felt itself drawn, not only for economic reasons but also owing to the many points of contact which existed between its standpoint, with regard to Central-European problems, and the chief circles in Prague. The frontier questions raised by the Peace Treaty were not settled in favour of Austria, which lost among other places the important railway centre of Gmünd. In the economic negotiations advantage was taken by the Czechs of Austria's dependence on the Bohemian coal [illegible]. On the other hand, in certain matters (naturalization, [illegible] protection of minorities, division of collections and [illegible]) a compromise was arrived at.

On the southern boundary Yugoslavia had to give up the [illegible] of Styrian territory which had not been assigned her by the Treaty of St. Germain. The Klagenfurt basin also remained Austrian, thanks to the result of the plebiscite of Oct. 10 1920, in which 60% of the votes were cast against Yugoslavia. Trade relations were established with the kingdom of the Serbs, Croats and Slovenes, as with other states, at first on a basis of exchange of commodities, but were later regulated by commercial treaties.

A variety of disturbances occurred from time to time in the relations with Hungary, where, at the beginning of Aug. 1919, the Soviet system had broken down. While the Christian Socialists viewed the new course of events in Hungary with sympathy, the Social Democrats and those with Great German sympathies—the latter because they saw their national aims endangered—were anxious lest the revolution in Budapest might bring about a restoration of the Habsburgs in the basin of the Danube. Causes of discord soon made their appearance. From the outset Budapest offered a scarcely veiled resistance to the cession of the Burgenland (German Western Hungary) to Austria. Austria declined to hand over Béla Kun and the other former "people's commissaries" who had taken refuge in Vienna; it even found itself bound, in consequence of the Copenhagen Agreement concluded with the party in power at Moscow, to aid the escape of the Hungarian Soviet leaders to Russia, in order to obtain the return of their own prisoners who were still kept in Russia. Only a few weeks before (June 20 1920) the International Trade Union Congress at Amsterdam had threatened Hungary with a boycott. Since this had only been exercised with severity in the case of Austria, the Hungarians regarded the Social Democrats of Vienna as having provoked it. The growing estrangement found expression in a few unfortunate frontier incidents, from the Hungarian side. It also had its effect upon the internal politics of Austria, for the Social Democrats sought to prove from documentary evidence that Hungarian Government officials, in their various conspiracies against the Austrian Republic, had relied on the support of the Vienna Christian Socialists.

At this point the coalition between the two great parties could no longer be maintained. The Christian Socialists had gradually become sick of it since the Social Democrats would not allow them as much influence as seemed in accordance with the increasing tendency of public opinion towards the Right. On the other hand, the Social Democrats, by their participation in a "bourgeois" Government, gave the Radical elements in their own party, as well as the Communists, a handle for attacking them, which threatened the carefully preserved united front of Social Democracy with serious danger. In view of this tension, an occasion which was not in itself of any special importance sufficed to split the Government coalition on June 10 1920. Otto Bauer could justly remark, on reviewing the past, that his party, by its coöperation with the Christian Socialists, had achieved as much as was possible for a beginning. The Republican legislation had answered, in so far as that was within the bounds of possibility, to the desires and interests of the urban proletariat. The position of the labouring class had also been recognized by the State. In the militia question the Social Democrats had entirely triumphed. Under the impression of the recent "Kapp-Putsch" in Germany they succeeded in forcing through a defense-law, which set up a machinery of soldiers' councils for the professional army provided for by the Peace Treaty; secured all political liberties, including also the right of coalition to those who had completed their service in the defense force, and by this means assured to the Social Democratic party for a long time to come predominant influence over the State's best source of power. As a set-off to these successes the Christian Socialists had managed with difficulty to protect their peasant franchise against inconvenient innovations, and to prevent questions of Church and State, education and the like from emerging in a critical form.

The place of the Renner Government was taken temporarily by a "Proportional Cabinet" ("*Proporzkabinett*") in which every party was represented by delegates without undertaking any responsibility for the Ministry as a whole; and it had to

carry on business up till the new elections, which were fixed for Oct. 17 1920. In the meantime it was naturally incumbent upon the Constituent Assembly to carry out its own particular task and give a definitive constitution to the "Federal State of Austria." Besides this the bill dealing with what had once been a considerable tax on property, namely the war-profits tax, was passed, under pressure from the Social Democrats in particular.

At the new elections the Christian Socialists obtained 82 seats, the Social Democrats 66, the Great German party (formed from the old German National party and kindred groups) 19, the German-Austrian Peasant party seven, the Bourgeois Labour party one. The distribution of the 92 seats in the newly created second chamber, the Federal Council (*Bundesrat*), represented a similar balance of power. On Dec. 9 1920 both Houses joined in the Federal Assembly (*Bundesversammlung*) in order to elect the Federal President, Dr. Michael Hainisch. The new Cabinet, composed of Christian Socialists and officials, was under the presidency of the Christian Socialist Dr. Michael Mayr,[1] who had already presided over the "*Proporzkabinett.*" While the Great German party assured the Cabinet of their benevolent neutrality, the Social Democrats went openly into opposition. They had had, indeed, to record a loss of votes in comparison with the 1919 elections, but they had none the less succeeded—in contrast with the fraternal conflicts of most other countries—in saving the party from disintegration. Even their relations with the Communists, thanks in no small degree to the platform of compromise adopted by the "Workmen's Councils" which were common to both sections of the party, had been tolerable up to the summer of 1920, though bitter hostilities afterwards broke out on both sides. Thus in Feb. 1921 the Austrian Social Democratic party had the satisfaction of holding together, in the spirit of its principles and under its patronage in Vienna, representatives of all international sections, from the Zimmerwaldians to the International Labour Association of Socialist parties. The tactical principles upon which this took place involved a compromise between the programme of action of the Second and the Third International, on which account the new Labour Association was given by its enemies the scornful title of the "International Two and a Half."

The pitiable condition of the Austrian State grew worse and worse. Neutral and former enemy countries did all they could to save the country from the worst; in particular, powerful relief measures of every kind had saved the population of Vienna from dying of hunger. It is true that the want of coöperation between the United States and the Western Powers had so far rendered it impossible to provide that far-reaching assistance which might ensure lasting salvation for Austria. Sir William Goode's plan for putting Austria into a sound financial condition, which clearly proved that the Austrian problem was not one of finance but a comprehensive political and economic one, had to be shelved, like those also propounded by Loucheur and Ter Meulen. At the end of March 1921 the Federal Chancellor Mayr learnt in London that the financial regeneration of Austria was to be handed over to the League of Nations, to which Austria had belonged since Oct. 1920. The "Austrian Section" of the Reparations Commission left Vienna a few weeks later (April 30 1921), the military supervisory commissions of the Allies having already been dissolved some time before. Financial delegates of the League of Nations arrived, to take up once again the study of the Austrian problem. The continued absence of organized help from the Entente had meanwhile—in spite of the counter-activity of the Vienna Christian Socialists, to whom is chiefly due the idea of a "Danubian Confederation"—strengthened Austrian opinion in favour of union with the large economic area of Germany. On April 24 1921 the overwhelming majority of the Tirolese declared themselves in this sense by a plebiscite which was carried out in defiance of the wishes of the Government; the Diets of other Territories proclaimed their desire to follow the example of Tirol. The ex-Emperor Charles's visit to Hungary at Easter had also called attention once more to these political questions. This occasioned two serious parliamentary conflicts, in the course of which the Michael Mayr Government was at times only able to obtain a majority of one. It was further evident that in spite of its conservative character the Cabinet had been unable to bring about an improvement in relations with Hungary. It could only have been purchased at the cost of concessions which would practically have amounted to the renunciation by Austria of the Burgenland (German Western Hungary). The position of the Government was only strengthened to a certain extent by the fact that in May 1921 all parties assured the Government of their support in the economic and financial measures desired by the League of Nations.

ECONOMIC CONDITIONS

The collapse of the Austrian Empire, as such, resulted in the rapid disruption of an extensive economic area and entailed the severance of an economically restricted German-Austria, which contained only little fertile land, from the agriculturally rich territories of the seceding states. Thus the early cessation of the food supplies which the states had been sending into Austria rendered the position worse, especially as regards Vienna, and even then, in the days of the transition period, the authorities had to appeal to foreign Powers to help in the relief of the food shortage. The anxiety to procure the primary foodstuffs remained the main preoccupation of the Austrian Government in the course of the ensuing two years. Accordingly, if the harvest returns of the years after the war be compared to pre-war showings, a marked falling-off of production is apparent. In the territory comprising the new Austria the net returns of the yield of wheat, rye and barley, which in 1914 amounted to 9,713,000 *meterzentners*, showed in 1919 only 4,518,000 *meterzentners*, and in 1920 an estimate of 5,300,000 *meterzentners*. Even if the level of pre-war harvests should be attained, only about half the requirements of the population could be met. During the last years which preceded the war an average production of 5 million mz. of flour was established, while the requirements at the time amounted to 9·5 million mz. The position was about the same with regard to other items of the supply of victuals. When the food problem became acute, especially as concerned Vienna, it immediately raised the question of the future of this city as a metropolis; for Vienna was the heart of a large empire, the seat of the administration of a large number of provincial industrial undertakings, and the centre of commerce and banking. Here the people had spent the income which they derived from all parts of the monarchy. Only gradually was it shown, in the first year of the republic, that the economic predominance of Vienna reposed upon a much more solid basis than had been assumed in some quarters.

At the time of the collapse the anxiety concerning the food supply found a parallel in the solicitude to obtain coal, since the Austrian output was almost wholly negligible. This, like many other products of primary importance, could be acquired only with great difficulty even in foreign countries, and, save to the extent in which it was obtainable on credit, could only be secured in moderate quantities by the release of counter-values.

The economic structure of the new Austrian Republic is best illustrated by employment statistics, which show that in 1910 agriculture absorbed 40%, industry and commerce 35%, mercantile avocations and transport 17%, the public services and the free professions 8% of the population settled upon its territory. It follows that the people were pretty evenly divided between agricultural and commercial pursuits; industry was for the most part concentrated in and around Vienna, to which city 1,800,000 of the 6,500,000 inhabitants of the state belonged.

Of the land by far the greater part is in the hands of larger or smaller peasant proprietors; 38% is covered with forests, 24% is agricultural or horticultural, 16% grazing-land in mountainous regions, 11% meadows. Conditions are relatively favourable for

the raising of live stock, as the census of April 1919 shows as many as 1,952,000 head of cattle and 1,107,000 pigs, which in comparison to the returns of 1910 reveals a decrease of about 40% as regards the latter, of about 20% as regards the former.

Austrian industry suffered grievously from the disruption of the economic area. To quote but one example: The yarn which was spun in the territory of present-day Austria was for the most part woven in the countries S. of the Sudetic Mountains. For the Austrian cotton-spinning industry, with its 1–2 million spindles, could employ a maximum of about 30,000 looms, but only about 12,000 of these are situated in Austria, so that under present conditions two-thirds of the product of the Austrian cotton-spinners would have to be finished off abroad. The cloth, as a finished article, used to be made up in Vienna and thence consigned to Hungary, Galicia, and elsewhere. Similar conditions prevailed also in other branches of industry in the old Austria, but, so long as there was but one connected, economic area, these conditions evolved themselves naturally, being governed by the geographical position of the factory. The setting-up of customs tariffs along the frontiers of the states which arose upon the territory of the broken-up Austria entailed serious difficulties for all industries. The fact that Austria was cut off from the areas upon which she was wont to draw for her supply of coal became a consideration of moment, since only 6% of the demand could be met by the exploitation of her own resources, while the balance required had to be obtained abroad. Private establishments had to be rationed as regards coal, and the use of gas and electricity to be drastically curtailed. In Vienna it was at one time even necessary to cut industrial establishments off the power stations. Industry received but a fraction of the coal it required, and the ironworks, in particular, suffered heavily in consequence.

The principal industries of the Austrian Republic are as follows: First and foremost is the iron trade. (Under normal conditions the *Eisenerzberg* in Styria furnishes from 20 million mc. upwards of iron.) The industry lies within the area of the *Südbahn* and around Vienna; it furnishes raw material and semi-manufactured articles which also form an item of the export trade. Very highly developed, it employed in pre-war days some 30–40,000 hands and manufactured scythes, tools, screws, wire of all kinds, hard iron wares, etc. The manufacture of machinery gave employment to about 21,000 workmen, its specialty being agricultural machinery. There are four factories in Austria which construct locomotives, several which build wagons, motor-cars, etc. Of the textile industry of the old Austria the bulk is now outside her frontiers, but an important part has remained (in the Vienna area and the Vorarlberg). The great clothing industry of the old Austria had Vienna for its centre. Two branches of industry depended upon Austria's wealth in forests—(1) the important timber trade (including the saw-mills, of which 257 were worked by steam and 5,200 by water-power; further, the furniture-manufacture, occupying about 14,000 hands); (2) the paper industry, which under full pressure furnished, in partly manufactured articles, 12,000 car-loads of cellulose and 10,000 of wood pulp; in wholly manufactured articles 7,000 car-loads of cardboard and 18,000 of paper, more than half of the products named being available for export. Further, in the working up of paper Austria is capable of good achievement. The electrical industry can employ some 25,000 hands, and the rubber and leather manufactures are of importance. Another important raw material remains to be mentioned: within the territory of the Austrian Republic an output of 200,000 tons of magnesite was reached in 1913.

The two years succeeding the war were industrially unproductive in Austria, because there was a lack of numerous raw materials, which were not to be had even for payment, since, owing to the universal shortage, difficulties were everywhere put in the way of export. After the *débâcle*, war industries came to a sudden standstill. The worst period of crisis was in the winter of 1918–9, and it was only in the summer of 1919 that a slow economic recovery began, based for the most part on the possibilities of export due to the conditions of the foreign exchange; at this time began on a large scale the "general clearance" of Austria by foreign purchasers who could take advantage of the low value of the Austrian *krone* abroad as compared with its purchasing-power at home.

The development of industry was wholly dependent upon the quotation of the *krone*, for in the spring of 1920 a slight improvement of the exchange in foreign markets caused a noticeable halt in exports, which only revived in the month of August of that year when the exchange was again on the down grade. In the autumn of 1920 a continuous improvement in the situation appeared in almost every industry; the frequent curtailments of working-hours gradually ceased, and new hands were engaged. By the close of the year the furniture-manufacture, clothing trade (including the specially prosperous shoe industry) and the leather trade showed well. Only the metal trades, which continued to suffer greatly from the want of raw material, could not definitely improve; the locomotive works and the electrical trade were fairly occupied, but the position was especially bad in respect of the manufacture of agricultural machinery and motor-cars.

In accordance with the social and political conditions of the first year of the war, a large number of social-political measures long demanded by the working classes had been passed. Of these some had been prepared and planned by the Austrian Government before or during the war, but had partly been shelved owing to political difficulties or the opposition of the classes interested in maintaining the old conditions; partly they had been unacceptable to the Government. Further measures of the kind seemed called for by the conditions of the moment, which urgently demanded State assistance for the classes of the population most hard hit by the economic depression, especially the rapidly growing class of unemployed whose urgency threatened violence. The most important measures were: enactment of the legal eight hours' working-day; new rules for work done at home and by children; prohibition of night work in bakeries; compulsory holidays for workers; compensation of workers and employees generally in the event of the transference of an industrial establishment or the sale of machinery abroad; legal regulation of collective bargains; establishment, on the analogy of the existing chambers of commerce and industry, of workmen's chambers (*Arbeiterkammern*) as the official representatives of the "estate" of workers; improvement of the conditions of domestic service by a special law.

A large part of this social-political legislation was occupied by the measures intended to combat the effects of unemployment. In addition to the common results of the ending of a great war, unemployment in Austria was increased, not only by the special causes already mentioned, but by the stream of Germans expelled from other parts of the former monarchy. Thus as early as Nov. 1918 State aid had to be introduced for industrial workmen and employees. The sums allowed for relief were fixed on the basis of the relief given in case of illness, and in Vienna, as a rule, attained the maximum provided for, namely six *kronen*, to which was added in the spring of 1919 a small bonus by the commune for fathers of families and in the beginning of 1920 a special additional grant by the State. The number of unemployed rose very rapidly: on Dec. 1 1918 for the whole of Austria the total was 46,000, on Feb. 1 1919 it was 162,000, on May 1 of that year the maximum of 186,000 was reached; but the decrease was slow, since the returns of Aug. 1 still showed 133,000 persons out of work, Nov. 2 87,000, end-Jan. 1920 69,000 and end-April 46,000. The number of unemployed was always greatest in the Vienna area, where the maximum was reached at the beginning of May with 132,000 unemployed, while on Nov. 22 there were 73,000 and end-April 1920 38,000 persons out of work. A very peculiar expedient was resorted to at the time when the conditions were at their worst. In order to occupy at any rate a part of the unemployed the factory-owners, who on April 26 1919 employed a minimum of 15 hands, were from May 19 of that year compelled to employ additional workmen up to one-fifth of their previous establishment and replace every man whose employ came to an end by a new man. This

measure, which was meant to remain in force for only a short time, was repeatedly prolonged all through 1920. Its terms allowed exceptions and modifications under certain conditions. But if industry was able to bear the weight of such measures at all, if it was found possible to comply with them at any rate on broad lines, that is probably due to the fact that when they were made trade was progressively improving.

The recovery of industry and quieting down of the political situation made it possible from Aug. 1919 to effect the necessary reduction in the relief of the unemployed, and by May 1920 to subject the whole matter of the relief of unemployment to legislative regulation. With this object in view—apart from the fixing of a maximum period of time within the space of a year during which relief was given—all unemployment doles were subjected to rigid conditions; further, all aid accorded was based on the principle of insurance, inasmuch as the State advanced the sums required for relief but thereafter recovered a third of the amount from the employers and a like proportion from the workmen by the contribution these were made to pay, so that it bore itself but a third of the total cost. The introduction of insurance against unemployment soon led to a considerable decrease in the total of persons who received relief payments (at the end of April a total of 46,000, of which 38,000 were Viennese cases, falling by the beginning of May 1920 to 19,000, of which 15,000 were Viennese). Thus from that time onward the number of unemployed in receipt of State aid decreased by about one-half. During the remainder of 1920 there was at first a rapid increase in unemployment, which was connected with the crisis then supervening (caused by the improvement in the exchange, which curtailed exports). By July the total of persons who were out of work and in receipt of relief reached 24,800 (of which total Vienna accounted for 19,500), but thereafter the totals again proved susceptible of rapid diminution, so that by the end of the year the decrease was illustrated by a return of 16,600 persons out of work (of whom 13,700 were Viennese). By the end of 1920 unemployment in Vienna was greatest among the metal workers (34,500) and unskilled hands (2,730), among shop assistants (1,338), the employees of hotels and restaurants (1,338), in the building trade (1,430), in the catering business (709). In this group, however, figures a large number of unemployed who were not in receipt of relief.

In the period which followed the termination of the war the Social-Democratic party acquired a leading rôle in the government of the country, its programme being to attain a new economic order by the nationalization of private enterprise. A number of laws were actually passed with this end in view. The law of March 14 1919 on the preliminaries of nationalization lays down in Paragraph 1: "On grounds of public utility suitable industrial concerns may be sequestrated for the benefit either of the State, the Territories or the Communes, and may be administered by the State, the Territory or the Commune, or placed under the administration of public, legally recognized bodies." For the elaboration of further legislation aiming at nationalization a Government Commission on Nationalization was instituted and given the right to call as witnesses persons capable of giving information, inspect industrial establishments, take cognizance of the account books, etc. The law of May 15 1919, which set up the industrial councils, was also meant to serve the ends of nationalization, since on these councils the working-men were to gain an insight into the administration of undertakings and be trained for their future task of exercising a determining influence upon the industry. At the same time the system of industrial councils was so planned as to fit into the economic order of capitalist individualism. "The industrial Councils are instituted in order to understand and to foster the economic, social and cultural interests of the working-men and the employees in the undertaking." They were to safeguard the observance of contractual obligations entered into collectively, and the compliance with laws protecting the working-men, etc.; under certain circumstances they could demand the production of the balance-sheet of the undertaking; in the case of public companies they deputed two representatives into the council of administration or the board of directors, though these were not conceded the right of speaking on behalf of the company or signing for it and had no claim to monetary compensation for services of this nature. The industrial councils undoubtedly proved useful in maintaining discipline in the factories during times of disturbance. The law of May 30 1919, on the procedure in cases of expropriation of industrial concerns, lays down very general maxims which deal with the provisions of future expropriation bills. Of importance is only the proviso that the process of expropriation is initiated by a resolution of the Government, which in itself entails definite legal consequences. The provisions for indemnification in the case of future expropriation, about which a lively discussion had raged, are very vague. The law of July 29 1919 on socialistic enterprises seeks, with a certain tendency to the idea of guild socialism, to remodel the legal forms of business undertakings so as at least to prepare for the transition to new economic forms. "The socialistic institutions (*gemeinwirtschaftliche Anstalten*) are founded by the State, by the Territory, by the Commune, or by a majority of these territorial corporations, with the object of transferring existing private and public undertakings to the proprietorship or the administration of the socialistic institutions, or of starting new undertakings in this form." These institutions were to be conducted by, among others, the corporations by which they had been established, the industrial councils of workmen and employees, and organizations representing a considerable part of the consumers of the institution's output. A series of such institutions was founded, partly in order to take over Government factories formerly engaged in turning out war material. Further socializing measures were arrested by the change in the internal political situation.

The economic condition of Austria noticeably improved in the course of 1920; "labour unrest" abated considerably, and by the beginning of 1921 a distinctly favourable progress was recorded in many branches of industry. This, however, could not obscure the fact that the development reposed upon thoroughly unsound basic conditions, especially upon the difference in the price level at home as against foreign countries with a healthy exchange, on a scale of wages which, calculated in foreign currencies, was extraordinarily low, while the national budget was weighted with milliards spent in the cheapening of food. As Austria could not within a measurable time meet her own food requirements she was dependent upon the export of manufactured articles. It could only be hoped that, on a return to normal times, Austria, after the recovery of the exchange, would become a suitable field for industry capable of meeting competition in the world market. The town of Vienna, thanks to its central position in Europe, must always be an emporium of increasing importance and also one of the principal centres of European trade. (K. P.; R. Sı.)

AUSTRIC FAMILY OF LANGUAGES.—An addition must be made to the classification of languages given in the article Philology (*see* 21.426) as the result of the further researches since 1908 in the Malay-Polynesian field and S.E. Asia. The establishment of the "Austric family" of languages may well be considered the most important achievement of these later years in the work of comparative philology.

The essential unity of the Oceanic languages, though partially recognized long ago by Humboldt in his *Kawisprache*, was not completely demonstrated until much more recent times. The connexion between the Polynesian and Indonesian languages (including the geographically outlying Malagasy) met with ready acceptance, but the affiliation of the Melanesian was not so easy. The difficulty was partly due to purely linguistic differences, the Melanesian type of speech being superficially very different from the Indonesian and Polynesian, partly to the diversity of the races which raised the natural, but quite unjustifiable, presumption that the languages could not be of the same stock. It was, however, eventually proved that Melanesian could not be kept out of the Oceanic family,[1] and it has since been shown that Micronesia, though different in race,

[1] Kern, "De Fidji-taal," *Verhand, Kon. Akad. v. Wet.* (Amsterdam, 1886), Afd. Letterk., Deel xvi.; "Over de verhouding van het Nufoorsch tot de Maleisch-Polynesische talen," *Actes du VIe Congrès International des Orientalistes.*

falls linguistically into the Melanesian section. Also it ultimately became plain that of these three subdivisions Indonesian best represented the archaic family type, while Polynesian at the other extreme had gone furthest in the direction of simplification and decay.[1] Thus was established, by the strictest scientific proof, the existence of the Oceanic or Malayo-Polynesian family of languages, extending from Madagascar in the west to Easter I. in the east, and from Formosa and Hawaii in the north to New Zealand in the south.

Meanwhile further exploration and research had revealed the existence in New Guinea and some of the neighbouring islands of a number of languages which could not be fitted into this scheme of classification, and did not even apparently form any family of their own, but only a number of distinct groups between which no ultimate relationship could be safely asserted.[2] These so-called Papuan languages (which have since been found in portions of Dutch and German as well as British New Guinea) are therefore to be regarded as a purely provisional group, the time for their systematic classification not having as yet arrived. But it is quite certain that they have nothing whatever to do with the Oceanic family, though some of the neighbouring members of the latter have undoubtedly been influenced and to some extent modified by Papuan languages, and also vice versa, particularly in the matter of syntax.[3] Moreover there exists in an outlying corner of Eastern Indonesia a small enclave comprising a number of closely related and very curious languages which differ profoundly from their neighbours of the Oceanic stock. These are the languages of the northern peninsula of Halmahera (or Jilolo), together with Ternate, Tidore, and a few other small adjacent islands. In spite of some attempts that have been made to show their ultimate connexion with the Oceanic family,[4] it cannot be said that the thesis has been proved or even rendered very probable. It is at least as likely that they are remnants of some archaic Papuan group, though the tribes that speak them are not Papuan in physical type.[5]

The Oceanic languages having thus been delimited,[6] there remained the further question of their source of origin. By an ingenious comparison of purely linguistic data, Kern had shown[7] that the common mother-tongue from which they were derived must have been spoken on some long coastline in the tropics, the east coast of Indo-China seeming on the whole to be the most likely one. Here there were actually languages, such as Cham and its immediate neighbours, which were plainly in some way connected with the Indonesian branch of the Oceanic family. But no really satisfactory attempt could be made to connect the Oceanic with any of the different groups of Indo-Chinese languages until the latter had been properly classified. This was done in part by Forbes[8] and carried further by Kuhn,[9] but the final achievement was the work of W. Schmidt. In a series of admirable monographs[10] he succeeded in proving the intimate connexion of the aboriginal languages (Sakai and Semang) of the Malay Peninsula, the Mon-Khmer group, the Palaung-Wa-Riang group of the Shan states, Khasi in Assam, Nicobarese, and finally the Munda languages of India proper. All these are characterized by a structure based ultimately on monosyllabic roots from which more complex words are formed by means of prefixes and infixes (in the case of Munda and Nicobarese, suffixes as well). Both in structure and vocabulary they are altogether different from the large family, or agglomeration, of languages to which Tibetan, Burmese, Siamese and Chinese belong.

On the other hand a considerable amount of work had been done, mainly by Dutch scholars such as Van der Tuuk, Kern, and Brandes, to analyze the structure of the Oceanic languages; they succeeded in showing that the superficial dissyllabism characteristic of the family was really the result of an ancient agglutinative system building upon originally monosyllabic roots.[11] This left the way open to Schmidt to show[12] that his newly formed synthesis of languages, which he proposed to call Austroasiatic, was ultimately related to the Oceanic (or as he would style it Austronesian) family, so that the two could be conveniently grouped under the generic name "Austric." Schmidt's arguments were based both on similarity of structure and numerous cases of identity between the very roots of the two families; and so far as they were confined to linguistic classification his conclusions have met with general acceptance at the hands of those best qualified to judge. But his attempt to establish a corresponding anthropological unity of the very diverse races speaking all these different tongues was not so successful and must be regarded as altogether premature. Most of these populations are blends, and though conceivably there may be some thin strain of common blood running through all of them, it is impossible as yet to define it or correlate it with the common element of their speech. Nor is any such assumption a necessary conclusion from the linguistic data. The synthesis of the languages has established a purely linguistic unity, implying no identity of race and admitting the existence here and there (*e.g.* among the Negritos of the Malay Peninsula, in Melanesia and even in parts of Polynesia)[13] of traces of older aboriginal languages embedded, like flies in amber, in the prevailing type of speech.

AVEBURY, JOHN LUBBOCK, 1st Baron (1834-1913), English banker (*see* 3.51*), died at Ramsgate May 28 1913.

AVIATION: *see* AERONAUTICS.

AYLMER, SIR FENTON JOHN (1862-), British general, was born April 5 1862, and joined the army in 1883. He served in the Burma campaign and the Hazara expedition of 1891, and greatly distinguished himself in the Hunza-Nagar operations, winning the V.C. and promotion to brevet-major in 1892. He took part in the Isazai expedition of 1892 and for his services in the relief of Chitral in 1895 was promoted brevet lieutenant-colonel. After some years on the staff, he commanded brigades in India from 1904 to 1910, was promoted major-general in 1909, and in 1912 became adjutant-general at Simla. This position he held until Nov. 1915 when, now a lieutenant-general, he was summoned to Mesopotamia to lead the force being organized for relief of Kut. This was composed mainly of two Indian divisions which had been fighting in Flanders and were arriving in driblets. The urgency of the situation obliged Aylmer to push up the Tigris with little preparation; but he inflicted two severe defeats upon the Turks before being brought up, 23 m. short of Kut, by the lines of Hannah on the left bank of the river. He halted for six weeks for reënforcements and war material before striking

afresh, this time on the right bank. His plan involved a long night march and assault on the enemy defenses, some 10 m. short of Kut, at daybreak. But one of his divisions did not arrive on time, and when delivered the attack failed; Aylmer was thereupon replaced by another general. He was given the K.C.B., and after returning to India he commanded a division there for some time. Gen. Aylmer was the author of an important tactical study on *Protection in War* (1912).

AYUB KHAN (1855-1914), Afghan prince, son of Shere Ali (*see* 3.77), died at Lahore April 6 1914.

AZCÁRATE, GUMERSINDO (1840-1917), Spanish politician and lawyer, was born at León, Spain, Jan. 13 1840, and was educated at the university of Oviedo, whence in 1858 he went to Madrid and graduated in law, science and philosophy (1861). After obtaining a post as assistant in a public office he returned in 1868 to Madrid as assistant professor of comparative jurisprudence and in 1872 was appointed professor. He was of the little band of Liberals who preferred to resign in 1875 rather than submit to the famous Orovio decree limiting the liberty of the chair. He was, however, reinstated six years later and became one of the central figures of the group headed by Don Francisco Giner, to which Spain owes most of its up-to-date educational institutions. He sat as deputy for León from 1886 to 1890, from 1891 to 1895, and for later periods. In 1892 he became professor of private law at Madrid. In politics he was a moderate republican. He was a keen student of English institutions and an admirer of English political life. In later years he accepted a share in official administration, notably as the head of the Instituto de Reformas Sociales, which he had invested with his incomparable moral authority. He had also approved of the Reformist evolution of Señor Melquiades Alvarez. The austerity of his political views was such that on being defeated at the last general election he fought, he refused a seat as senator for life, which was offered him by the Government. He died at Madrid Dec. 14 1917.

AZCÁRRAGA Y PALMERO, MARCELO (1832-1915), Spanish soldier and politician, was born in Manila in 1832. He early saw service in Spain during the mutinous outbreaks in Isabella's reign (1854-6) and was next sent to Cuba and on a special mission to Mexico, later belonging to the expeditionary army against that country. He was promoted colonel in 1866 and entered the Ministry of War. He was employed by the Spanish republican Government of 1868 as chief of staff at Cartagena and later of the army of the North. After the accession of Alphonso XII. he became field marshal and Under-Secretary for War. He sat as deputy for Morella in the first restoration Parliament. In 1885 he was elected senator for Navarre and was Minister for War under Canovas (1891-2) and again in 1895, becoming head of the Cabinet in 1897 after Canovas's assassination. In Sept. 1904 he retired from the army at the age of 70 with the rank of general, and in Dec. of that year was again for a few weeks prime minister. Throughout his political career he was associated with the Conservatives but took little part in party struggles. He died May 30 1915.

AZERBÄIJÄN.—The republic of Azerbäijän had no political existence until the year 1917, when the Trans-Caucasian provinces of the Russian Empire, exposed to the enemies of Russia, found in the collapse of the empire the need and opportunity of striking out for themselves. Nor has Azerbäijän any national traditions or history; scarcely, till lately, had her people a racial consciousness, the name, even, did not apply to the present state. Under Russian administration Trans-Caucasia comprised six " Governments." Of these Baku, with a coastline on the Caspian Sea, and Elisavetopol, adjoining Baku on the west, united to form the republic of Azerbäijän. The territory included in the two " Governments " was, originally, the portion of the Persian province of Azerbäijän (*see* 3.80) ceded to Russia as long ago as 1813 under the predatory Treaty of Gulistan. Once a Russian possession, the ceded area lost all connexion with its previous name. But when in 1917 the two " Governments " combined to declare a joint independence the Persian name was adopted for the infant state from motives of policy—it was hoped thus to attract to the new republic the Persian remainder of the old province of Azerbäijän, peopled chiefly by the same stock.

Geographical Position.—Looked at broadly the republic occupies the lowlands of two great Caucasian river basins—the Kuru and the Aras—enclosed by the Caspian Sea, the Caucasus mountains, the watershed parting of the Black Sea, and the highlands of Armenia and Persian Azerbäijän. This fertile territory, rich also in oil, has a coastline to the Caspian exceeding 400 m., and stands athwart the chief line of communication between the Black Sea and central Asia. Two-thirds of its population is a homogeneous race of Tatar origin closely related to the Anatolian Turk. They speak a form of Turkish, but, unlike the Turk, are Moslems of the Shiah sect: with their Sunni kinsmen of Anatolia they have, however, a definite sympathy.

Area and Population.—The area of the " Governments " of Baku and Elisavetopol together was about 32,000 sq. m.; their pop., by the Russian census of 1916, somewhat less than 2,600,000. This total comprised, in round figures, 1,740,000 Moslems, 540,000 Armenians, 230,000 Russians and other Europeans, and diverse elements as the remainder.

The territory claimed by the republic is not, however, altogether that of the " Governments " of Baku and Elisavetopol; but it is only of these that definite figures of area and population can be given. For districts containing in all some 15,000 sq. m., partly within and partly without the boundaries of the two " Governments," and carrying a pop. of nearly a million, are in dispute between Azerbäijän and the adjoining republics of Erivan and Georgia. Settlement of these disputes may give Azerbäijän a greater or lesser area and population than had the two " Governments."

Industries and Communications.—The chief industry of the country is the production, refining, and exportation of oil and petroleum. Within 50 years the immense oil deposit discovered on the Apsheron peninsula had created the city of Baku, now the capital of Azerbäijän, with a pop. of 250,000. Indeed the production of oil in vast quantities in this region has had far-reaching indirect political results. It has given the state an importance out of proportion to its population, by placing wide adjoining regions in a position of dependence regarding the vital commodity of oil for light and fuel. Still more, it has profoundly affected the direction given to lines of railway, and the development of rail and other forms of communication.

By this process, and from the position of Baku as a port on the Caspian Sea—a sea nearly twice as great in area as all the Great Lakes of America together—the city became a centre with lines of communication, by rail and sea, radiating from it in all directions. From Baku the Caspian Sea is crossed by ferry steamers to Krasnovodsk; and thence a railway runs for nearly 2,000 m. through central Asia, skirting the Afghan frontier, and reaching the Pamirs. The city is in direct rail communication with Moscow; by railway, sea, river or canal every part of European Russia, in fact, is within reach. By sea N. Persia ports are only one day's steaming. Through Trans-Caucasia Baku is in direct railway communication with Erivan, Tabriz in N.W. Persia, Erzerum in Turkey, and Batum on the Black Sea. Batum, indeed, is complementary to Baku as the terminus not only of the Baku-Black Sea railway, and of the pipe-line for conveying oil, but as the one port by which the great inland centre of communication and oil production, embedded deep in western Asia, can have trade intercourse with the oceans and outer countries of the world. The interdependence of Baku and Batum was well enough with all Trans-Caucasia under one Government; with the two cities in separate states friction became inevitable.

Had there been no oil at Baku events in the Near and Middle East during the years 1913-21 would have shown a striking dissimilarity from the events which actually befell. Such is the important position Azerbäijän fills, by reason of Baku, on the confines of south-eastern Europe and western Asia.

External Influences.—In the Pan-Islamic dreams cherished by the Young Turk leaders of Turkey, the republic, with Persian

Azerbäïjän, forms the essential connecting link between Islam of the West and Islam of central Asia and India. Pan-Islamic policy therefore closely affects Azerbäïjän. But a further and more serious disturbing influence has been provided by Bolshevik Russia. For economic reasons, and in pursuit of her ambitions and policy in south-western and central Asia, the geographical position held by Azerbäïjän made control of the republic a pressing necessity. The short and varied history of this small Caucasian state is, in consequence, concerned chiefly with the interaction of Turkish and Russian policy, and the inevitable question of Armenia and the Armenian people.

History.—The history of Azerbäïjän as an independent state may be said to have begun on Sept. 20 1917. During the spring and summer of that year upheaval in Russia had passed from symptoms to facts of omen for the world. In March the Government resigned, a Provisional Government was proclaimed, and the Tsar abdicated; and in April the Provisional Government issued its proclamation declaring for the self-determination of peoples and the establishment of a lasting peace. In June the Black Sea fleet mutinied, and the Russian armies in Asia Minor, saturated with Bolshevik theories and shouting "No annexations and no indemnities!" abandoned their positions before the enemy and retired behind the Russo-Turkish frontier of 1914. On Sept. 15, Russia became a republic.

Need for common action by the Caucasian peoples was evident, as the Turkish front was held now by troops whose military value was fast disappearing. There was, further, at least on the part of Georgians and Armenians, a genuine desire to use the opportunity for securing some form of independence which should safeguard their national rights. The creation of the Russian Republic was followed, two days later, by a Council of the Trans-Caucasian peoples, assembled at Tiflis, proclaiming Trans-Caucasia a Federal Republic. This step involved removing a Russian Bolshevik Commissar who had already been sent to Tiflis to replace the Viceroy and Commander-in-Chief, the Grand Duke Nicholas. The Commissar was ejected, but he transferred himself to Baku and there with Armenian aid established a Bolshevik Government. But the affairs of the Federal Republic did not prosper. Between Georgian and Armenian Christians, and the Tatar Moslems of Azerbäïjän, were antipathies of race and faith not to be suddenly diminished or held in check. Each people, too, had its own particular interests to consult. Jealousies and rivalries were acute; Erivan and Azerbäïjän had deep suspicions that Georgia was scheming to use the Federal Republic for converting all Trans-Caucasia into a Georgian state. A fundamental opposition of outlook also existed on the part of each. All three desired to come under British protection; but that being impossible Azerbäïjän stood out for Turkey, Armenia for Russia, and Georgia for Germany as the powers best suited and able to assure Trans-Caucasian independence. To the leaders of each of the federated peoples, in fact, the essentials of a rapidly changing situation ever appeared different.

The Treaty of Brest Litovsk, between Germany and Russia, signed on March 3 1918, was followed by a Turkish invasion of Armenian territory in order to occupy the districts awarded Turkey under the treaty. Batum was another district allotted to Turkey, subject to self-determination by the inhabitants; but Georgia believed that with German aid the province might be preserved for herself. In effect the Federal Republic was now at war with Turkey, though with no intention or possibility of concerted action amongst its peoples, and the Turkish occupation proceeded in spite of resistance on Armenian territory. Batum, too, was entered by Turkish forces on April 15. In these circumstances the republic resolved, on April 23, to make a formal declaration of independence, and to open peace negotiations with the Turks. But a German penetration of Trans-Caucasia from the Ukraine was now in sight. Odessa and Sevastopol were both in German hands at the beginning of May, and Georgian policy looked more and more definitely to Germany, to the exclusion of the wider interests of the Federal Republic. A few days later German and Turkish delegates reached Batum to negotiate peace between Georgia and Turkey. This matter completed, Georgia and Germany concluded a treaty between themselves, by which German troops were admitted to the country, and Georgia received promises of protection, the maintenance of her independence and financial assistance.

As has been said, a Russian Bolshevik Government had been established at Baku after the founding of the Federal Republic of Trans-Caucasia. The area it controlled was small, but the Government had the advantages of position, supplies of fuel and food, and the comparative wealth afforded by the large and prosperous population. The Russian element behind the Government was also supported by local Armenians, a section of the inhabitants numbering some 60,000. These Armenians were under the influence of the Dashnakists, the Armenian revolutionary society of extremists, whose methods were violence, and who leaned towards Bolshevik Russia. And now, early in March, when the affairs of Trans-Caucasia were at their lowest, and the existence of the Federal state hung in the balance, the Russians and Armenians of Baku ejected the Tatar Moslems of the city, and massacred some thousands. During the succeeding three months, massacre of Moslems by Armenians spread to various parts of what had been Russian Armenia. With Georgia in private alliance with Germany, and Armenians massacring Azerbäïjän Moslems whenever opportunity offered, the Federal Republic of Trans-Caucasia had become to all merely an empty name.

The Federal Republic was dissolved on May 26 1918. On that date Azerbäïjän and Georgia each proclaimed its separate existence as an independent republic and formed a National Government; at the same time the National Council of Armenia took control of Armenian affairs. As the independent Bolshevik Government of Baku still existed Elisavetopol became the capital of Azerbäïjän for the time being. Turkish troops were now admitted to the Tatar Republic; and others, followed by Germans from Georgia, reoccupied Tabriz, the capital of Persian Azerbäïjän, at the end of May. The Pan-Islamic policy of Turkey appeared to be prospering at this time, and its leaders looked eastward to making their next step into central Asia. With this as a possibility a small British column under Gen. Dunsterville advanced from Mesopotamia through western Persia to the Caspian, and passing thence by sea reached and occupied Baku on Aug. 16 1918. Its purpose was to countenance and support the Russo-Armenian force holding the town and to assist the republic of Erivan, and thus prevent Turkish or German operations in central Asia. But the assistance and coöperation expected of the local troops did not come up to anticipation; a large Turkish force compelled the British to reëmbark on Sept. 13; and Baku fell the following day. But Turkish and German operations in these regions were drawing to an end. The Armistice between the Allies and Turkey, signed on Oct. 30, and between the Allies and Germany 12 days later ensured the evacuation of Trans-Caucasian and Persian territory by Turkish and German troops. A British force from Persia reoccupied Baku on Nov. 16; a British garrison was placed in Batum on Dec. 27; and before long a whole British division had reached Caucasia to ensure the evacuation of Turks and Germans. The railways were repaired, and through traffic between the inland republic and Batum resumed under a British Board of Railway Control, thus preventing the acute friction of the past.

On the withdrawal of Turkish troops from Baku the Government of Azerbäïjän was established there, and endeavoured to organize an administration. This was a work of infinite difficulty, for though the Moussavet party in power meant well, every kind of administrative experience and knowledge was lacking. The British military authorities assisted, but soon found it necessary to take over multifarious civil functions, from providing and rationing foodstuffs, suppressing profiteers, working the oil and shipping industries, and managing the State bank, to the administration of Posts and Telegraphs, Police and Justice. For the first time since Russian Government ceased in Trans-Caucasia order appeared in the republic. But the

change depended on foreign ability and experience, and when the British troops were withdrawn in Aug. 1919 Azerbäijän relapsed into administrative confusion. An inter-state control of railways only was provided with some success, as a matter vital to all Trans-Caucasia.

The Peace Conference of the Allies which began its sittings in Paris on Jan. 18 1919 did not greatly affect Azerbäijän, though the republic sent a delegation to represent its claims to large territorial extensions. The course taken by events in Trans-Caucasia before the Treaty of Sèvres was finally drafted doubtless placed Azerbäijän outside the area to which it was thought treaty provisions could be applied. Except regarding frontiers in dispute between Azerbäijän and Armenia the Treaty of Sèvres, therefore, avoided matters affecting the Tatar Republic. For these frontiers it provided that they should be settled by direct agreement between the states concerned; and, failing such agreement, they were to be determined by the principal Allied Powers.

The Conference gave, however, no little attention to the problems of Trans-Caucasia. Early in 1919 it offered Italy control of the whole area, she having many interests there; but the offer was declined after consideration. As an emergency measure the Supreme Council appointed an Allied high commissioner to prevent territorial disputes developing into hostilities between the republics; and by his influence neutral zones for the time being were established, and the situation was temporarily eased. But months passed and the Conference became more and more chary of intervening in Trans-Caucasian affairs, especially in view of Gen. Denikin's operation in Cis-Caucasia, and his aim of reuniting south-eastern Russia. Stated shortly the shadow of Russia—Russia both of the present and of the future—lay over the land and created an incalculable situation. *De facto* recognition was, however, accorded all three republics. It should be noted, further, that in the draft of the Treaty of Sèvres the importance of Batum to Azerbäijän and Armenia was recognized by making the town and surrounding territory a free state under the League of Nations, and giving the inland republics definite rights in the port and of access by rail. But this plan fell through, and Batum was returned to Georgia, under an agreement confirming Azerbäijän and Armenia in the privileges they were to have received from the free state of Batum.

The Turkish Nationalist movement which became all-powerful in Anatolia in consequence of the Treaty of Sèvres had a serious influence upon the republic of Azerbäijän. Nationalist Turkey and Soviet Russia each found itself opposed to the Allied Powers. They therefore followed a common policy up to a point; and Turkish Nationalism and Russian Bolshevism went hand in hand, supplying each other's needs as far as might be, whether of means, material or opportunity. Turkey sought to recover the provinces in Trans-Caucasia from which she had been ejected by the Allies in 1918; she also required munitions from Russia, and direct access to Azerbäijän and central Asia in execution of her Pan-Islamic ambitions. Russia had her own quarrel with the Allies to pursue, and her revolutionary mission to accomplish where she could. The oil of Baku, further, was a necessity for her economic life. These different aims of both countries converged on Trans-Caucasia, and implied the bringing of Turkish and Russian territory to a coterminous frontier—at least to a common frontier of effective control. Once this was attained all other things would be secured, including direct railway communication between Russia and Anatolia. Denikin had been driven out of Russia and now only the independent republics of Azerbäijän, Erivan and Georgia stood in the way.

Russia therefore prepared to set up a Soviet Government in Azerbäijän, and under cover of this change reëstablish Russian control first there, and afterwards in all Trans-Caucasia. On April 28 1920 the XI. Soviet Army from Cis-Caucasia, some 50,000 strong, entered Baku without fighting. Simultaneously a rising of local Bolsheviks declared the Republican Government deposed, and established in its place a Soviet Government in alliance with Moscow. The Russian army, it was said, had only come to place the proletariat of Azerbäijän upon its feet. Effective opposition to the revolution was found impossible. The Azerbäijän army was disbanded; a revolutionary committee set up which sent the members of the late Government and many leading anti-Bolshevik citizens to execution; and Bolshevik economic theories were rigorously applied. Having seized the railways and consolidated their position in the country the Bolsheviks attacked Georgia and Erivan across the frontiers of Azerbäijän, but were repulsed without much difficulty. Russia's campaign in Poland was in progress at the time, and not going well, and further aggressions in Trans-Caucasia were therefore suspended. During this pause a Tatar rising took place at Elisavetopol, in which several thousand Bolsheviks were massacred. The rising was promptly suppressed by Bolshevik troops; and they, aided by local Armenians, retaliated by massacring, it is said, some 15,000 Tatars of both sexes and all ages. From this affair arose the hatred which the Tatars of Azerbäijän have since displayed against the Bolsheviks.

Further Bolshevik and Turkish operations against Georgia and Erivan do not properly belong to Azerbäijän history, but they cannot be altogether ignored. Suffice to say that when Russia, in the autumn, was relieved of her Polish embarrassments, and the campaign of Gen. Wrangel from the Crimea had plainly failed, she and her Turkish Allies turned their attention once again to Trans-Caucasia. By the end of Nov. both Georgia and Erivan were crushed, and Soviet Republics, dependent on Moscow, established in place of the National Governments. Turkey regained the districts of Ardahan and Kars; in addition she was given the strip of Armenian territory through which passed the railway from Azerbäijän to the Turkish frontier; but Russia with an eye to her own future, insisted that Batum should form part of Georgia, and her will in the end prevailed. Russia, in fact, had recovered all but an insignificant portion of her Trans-Caucasian provinces; and Azerbäijän, Georgia, and Erivan ceased to exist as independent states, except in name.

(W. J. C.*)

BACCELLI, GUIDO (1830–1916), Italian physician and politician, was born at Rome 1830, and died at Rome Jan. 11 1916. After graduating in medicine at the university of Rome, he was appointed assistant professor of medical jurisprudence in 1856, and some years later became professor of clinical medicine. He soon acquired a great reputation as a practising physician, being especially noted for the accuracy of his diagnosis, and he devoted himself particularly to the pathology of the heart and to malaria; his studies on the latter subject proved of great value for the reclamation of the Roman Campagna and other fever-stricken zones. In 1875 he was elected deputy for the 3rd Div. of Rome, which he continued to represent until his death. He was Minister of Education in the Cabinets of Cairoli (1879–81), Depretis (1881–7), Crispi (1893–6), and Gen. Pelloux (1898–9), and of Agriculture under Zanardelli (1901–3); from 1889 to 1893 he was vice-president of the Chamber. A keen classical scholar, he took an active interest in archaeological matters, although in some of his projects, such as the famous *Passeggiata Archeologica* in Rome, he showed more enthusiasm than judgment. His labours for the isolation of the Pantheon and the creation of the Museum of Ancient Art and of the Modern Art Gallery in Rome deserved and met with more general approval.

BACON, HENRY (1866–), American architect, was born at Watseka, Ill., Nov. 28 1866. In 1884 he entered the university of Illinois to study architecture, but in the following year began work in the office of Chamberlin & Whidden, in Boston, where he remained three years. From 1888 to 1897 he was with McKim, Mead & White, in New York, excepting the years 1889–91 which he spent in Europe as Rotch Travelling Scholar. From 1897 to 1903 he was a member of the firm of Brite & Bacon, in New York, and thereafter practised alone.

Among his important works were the Court of the Four Seasons at the Panama-Pacific Exposition; the Union Square Savings Bank, New York City; the Public Library, Paterson, N.J.; the Waterbury General Hospital, Waterbury, Conn.; and the Whittemore Memorial Bridge, Naugatuck, Conn. Of numerous monuments, some designed in collaboration with various sculptors, the following should be mentioned: the Lafayette Monument, Brooklyn, N.Y.; the Lincoln Monument, Lincoln, Neb.; the Longfellow Monument, Cambridge, Mass.; the Republic Monument and the Centennial Monument, Chicago, Ill.; the President Harrison Monument, Indianapolis, Ind.; the Civil War Memorial and World War Memorial, Yale University; and the Parnell Monument, Dublin, Ireland. In 1920 the Lincoln Memorial, at Washington, D.C., designed by him, was completed, costing more than $2,500,000.

BACON, ROBERT (1860–1919), American banker, was born in Boston, Mass., July 5 1860. He graduated from Harvard in 1880 (in the class with Theodore Roosevelt), and the following year entered the banking house of Lee, Higginson & Co., in Boston. In 1883 he became a member of the firm of E. Rollins Morse & Bro., and in 1894 joined the house of J. P. Morgan & Co., in New York. After conspicuous success in the financial world he resigned in 1903. He was Assistant Secretary of State, 1905–9, and then for a short time was Secretary of State, succeeding Elihu Root on the latter's election to the Senate. He was ambassador to France from 1909 to 1912. He attended the first Plattsburg Camp and was commissioned major in the U.S. Reserves in 1917, being assigned to the staff of Gen. Pershing with the A.E.F. in France. He returned to America with the rank of colonel, in 1918, and died in New York City, May 29 1919.

BACTERIOLOGY (*see* 3.156).—Since bacteriology is so comparatively young a science, dating, as it does, from the introduction by Koch in 1880 of methods of technique which have made it an exact science, it is not surprising that the decade from 1911 to 1921 saw very considerable additions to our knowledge of the life and functions of the microörganisms with which it is concerned. These additions to knowledge will be reviewed here under two headings: general and agricultural, and medical.

I. General and Agricultural

Variations in Bacteria.—It is probable that nuclear fusion between male and female gametes is essential for the preservation of the *special* characters of an organism, and that in absence of sex fusion a species will tend to break up into a number of different strains. So far no fusion, either sexual or otherwise, has been observed amongst the bacteria. The characters of bacteria are extraordinarily liable to change according to the conditions of cultivation. Variations in morphology, cultural characters, physiological behaviour, virulence and pathogenicity have constituted one of the most striking features of modern bacteriology. Innumerable instances of such variations have come to light; space will permit of the citation of only a few typical cases.

Bacillus coli in the peritoneal cavity in the case of ascites may take the form of a diplococcus; in milk or in urine it may develop into a dense network of branching filaments resembling *B. anthracis.* Again *B. carotovorus*, an organism causing disease in many vegetables, when present in the plant tissue appears as a very small rod; cultivated on artificial media the rods are much larger; in broth it grows in the form of long branching filaments, and in broth containing sublethal doses of antiseptics, *e.g.* phenol and alcohol, it develops as a minute coccus.

It has recently been shown in separate communications that certain organisms, *B. lepisepticum* and *B. dysenteriae*, when cultivated on artificial media, segregate each into two distinct types, one forming round colonies, the other diffuse and spreading ones; these types show variations also in agglutinability and in virulence, though otherwise their specific characters are identical. Once separated, the spreading forms in both cases remain true to type, and the question arises whether both strains coexist in the materials taken from the infected animals or whether the spreading forms appear as mutants shortly after removal from the natural habitat. This question can only be answered by investigations of cultures derived from single cells: the finding of segregation of mutants in cultures of this type would be of the greatest interest, but at present such investigations have not been conducted.

The sugar-fermentation reactions upon which much reliance is based in the diagnosis of species are unfortunately very susceptible to change under different cultural conditions; organisms can be " trained " to acquire fermenting powers which they do not normally possess. Strains of *Bacillus carotovorus* isolated from diseased plants grown in different localities were found to possess many various sugar-fermenting powers, but when cultured simultaneously through several transfers under the same conditions and again tested, all gave identical reactions.

All pathogenic organisms rapidly lose the property of virulence when cultivated apart from their hosts, and once lost it is very difficult to restore this character. Virulence is altered rapidly by a change of environment; the attenuation of the anthrax bacillus by cultivation at 40° F. instead of at blood temperature is a well-known phenomenon. Similar rapid reduction in virulence is attained by cultivation of organisms in presence of antiseptics.

One and the same species of an organism may give rise to different symptoms of disease in different individuals. The pathogenicity of *Bacillus anthracis* is considerably altered by exposure to the ultraviolet rays; the symptoms produced on inoculation of the altered strain into an animal are quite unlike the normal symptoms of anthrax. The change which the organism undergoes in the treatment with the ultra-violet rays persists after daily subculture for upwards of two months.

Transmutation in Bacteria.—Many experiments have been described wherein bacteria became so changed in character as to suggest that they had undergone transmutation. One must not forget, however, that usually in dealing with cultures of bacteria one has a mixed population, the progeny of several individuals. Even though the culture may be made from a single colony on a plate it is more than probable that such a colony has arisen from a number of organisms herded together. The method of culture of such a population will tend to favour one strain and depress others, so that this strain may eventually be separated and appear as a mutant.

One piece of work, however, which requires confirmation before it can be accepted, should be cited in this connexion. It has been stated in a preliminary communication that *Azotobacter* may give rise to practically every form of organism to be found in the soil. The large round form of *Azotobacter* is said to pass in old cultures into a plasmodial stage from which it may emerge in the various

forms of bacilli, cocci, sarcinae, clostridia, etc.; in fact, all the forms common in the soil are held to be only stages in the life cycle of a single species. If this should be confirmed by future investigations, the whole basis of the science of bacteriology will be profoundly modified.

Industrial Applications of Microbiology.—In the fermentation industries much use has been made of the variations that can be induced in microörganisms by cultural methods. For example, in the alcoholic fermentation by yeast glycerine figures as a by-product to the extent of some two or three per cent of the sugar fermented; by the addition of sodium sulphite to the fermenting complex the process is profoundly altered and the percentage of glycerine is increased to some 33 per cent. Again, dextrose is converted by *Citromyces* into citric acid, oxalic acid and carbon dioxide; the percentage of citric acid is normally not great, but by high concentration of sugar and low concentration of nitrogenous food it can be raised to 50%. The production of acetone and that of alcohol from maize by biological methods are processes which have been successfully worked during the World War, and encourage one to look forward to considerable developments of microbiology as applied in the factory.

Bacteria of the Soil: Partial Sterilization.—Researches at the Rothamsted Experimental Station have proved that soils which have been treated with certain volatile antiseptics or heated to temperatures between 56° and 100° C. show a marked increase in fertility. This results from a parallel increase in the bacterial activity, whereby the rate of the conversion of the organic nitrogenous matter of the soil into nitrogen compounds which are readily available as food for the plant is considerably enhanced. The number of bacteria normally present in soils varies from about 4 to 60 million organisms per gram. Under the above treatment with antiseptics or heat the majority of these are destroyed and the number of active bacteria is reduced to a few hundreds only. By no means all are destroyed, however, since many of the organisms of the soil are of the spore-forming kind and are thus able to withstand the treatment. After the removal of the volatile antiseptics, or after cooling of the soil, the germination of the spores is unhindered and the bacterial population of the soil is quickly reëstablished. The treatment renders the soil more suitable as a medium for bacterial growth, so that the number of organisms quickly exceeds by some six or sevenfold the original bacterial content of the soil, or rather that of a control sample of untreated soil kept under the same physical conditions as the treated sample. This remarkable discovery was made in 1909. As a matter of fact it was not an entirely new discovery; reference to the literature showed that the phenomenon had been observed many years earlier by German scientists, but they had curiously failed to grasp the important significance in its relation to the fertility of the soil. Naturally under such drastic treatment the bacterial flora of the soil does not remain unaltered; many species, in fact practically all those which do not form spores, are entirely annihilated. The very important group of ammonia-producing organisms contains, however, very many of the sporing kind, and the increased fertility of the soil is mainly due to the increased production of ammonia. The nitrifying bacteria on the other hand are destroyed, and on the belief, current at that time, that the nitrogen of ammonia had first to be converted into the form of nitrate before it could be utilized by the plant, it was difficult to explain the increase in fertility. It has been shown, however, that this belief had no real foundation but that, in the absence of nitrates, plants can obtain their necessary nitrogen in the form of ammonia and many other of the simpler nitrogenous compounds.

The enrichment of the soil as a medium for bacteria seems to be the result of the removal of an inhibitory factor which militates against bacterial development. This factor *in all probability*, although the hypothesis is not universally accepted, is the protozoal fauna of the soil. On this view, which is supported by the strongest circumstantial evidence, though at the moment direct proof is lacking, the protozoa living mainly upon bacteria keep down the numbers of the latter within the limits stated above, and the removal or depression of the protozoa by partial sterilization results in a corresponding enhancement of bacterial activity.

Methods have recently been developed at Rothamsted by which the numbers of the different protozoa can be ascertained and the interesting fact has come to light that encystment of the protozoa takes place with rhythmic periodicity; certain species investigated pass from the trophic to the resting condition simultaneously every forty-eight hours, a phenomenon which has its parallel in the development of the malarial parasite in the human blood. By counting daily the numbers of protozoa, active and resting, and relating these to the numbers of bacteria in the soil, it has been shown that the bacterial numbers vary inversely with the numbers of the trophic amoebae.

The effect of partial sterilization upon the fertility of the soil is such that it has become a common practice and a paying proposition for the nurserymen in the cucumber- and tomato-forcing industries to sterilize their soils either annually or every second year. The beneficial effect is of rather short duration and in the course of a few years the soil reverts to its former degree of productivity, and in some cases shows, after the initial enhancement, an actual reduction of fertility. These facts are not easily explained on the current hypothesis as set out above. Much attention was being focussed upon the subject in 1921, and very interesting results were being obtained by the workers at the Rothamsted station, results which bid fair to revolutionize accepted views, so that the future might well produce a theory more in accordance with the facts.

Nitrogen.—It has been recognized for some time that the nitrogen-fixing organisms of the soil are physiologically dependent for their energy upon carbohydrates, and that the amount of atmospheric nitrogen they are able to fix bears a close relationship to the amount of carbohydrate material used up. It was demonstrated in 1915 that the amount of fixation of nitrogen was also influenced by the presence of simple soluble nitrogenous compounds in the soil solution; urea, glycocoll, formamide, etc., had a marked effect in depressing the amount of nitrogen assimilated. These results have been fully confirmed, and it is now known that so long as an available supply of soluble nitrogenous matter is present the organisms will make use of this source in preference to that of free nitrogen, for which a greater expenditure of energy on their part is required.

It is only in recent years that the energy relations of soil bacteria have received due consideration; in 1916 it was pointed out that *Bacillus mycoïdes*, a typical member of the group of ammonifiers, produces ammonia, not as an essential by-product of its metabolism, but rather in virtue of its power of obtaining energy from the protein molecule. If other sources of energy are available, *e.g.* carbohydrates, these will be drawn upon in preference to the protein molecule with corresponding diminution of ammonia production; in fact, in presence of much carbohydrate the proteins will be entirely neglected and the organism will utilize the ammonia present in the soil as its source of nitrogen, thus competing with the growing crop. Probably most of the bacteria and moulds of the soil are capable under suitable conditions of assimilating ammonia. The process has not been observed in soils poor in organic matter, but in peaty soils it has been demonstrated to the extent of some 30% of the added ammonia.

Obviously then, in the use of farmyard manure, the proper ratio of carbohydrate to protein material is a matter of considerable importance. If the amount of carbohydrate is in large excess, most of the bacterial species will tend to reduce the quantity of nitrates and ammonia already existing in the soil; at the same time under these circumstances, provided the temperature conditions are satisfactory, the nitrogen-fixing organisms will work energetically. The effect will be a temporary depression of fertility, but eventually the nitrogen fixed will become beneficial to the growing plant.

If the material is particularly rich in protein the organisms will produce considerable quantities of ammonia and the effect will be at once beneficial.

If the air supply is insufficient the organisms will tend to produce denitrification, taking some of their oxygen from the nitrates and liberating nitrogen as gas. It has been shown that dressings of farmyard manure may in exceptional cases do more harm than good.

Symbiotic Nitrogen Fixation.—At the commencement of the decade the application to the soil of cultures of *Pseudomonas radicicola* was advocated as a means of improving the crops of leguminous plants. As far as the soils of the Old World are concerned hopes of such improvement have been shattered by experience; its soils are already heavily infected with the nodule-producing organism and to inoculate them with any more is merely a case of "bringing coals to Newcastle." In the New World virgin land exists which has never carried leguminous crops; here inoculation with pure cultures of the organism has met with marked success. Although from an economic point of view the study of symbiotic nitrogen fixation has lost much of its interest, in its academic aspects it still retains undiminished fascination. The adaptability of the organism has been further investigated and it has transpired in cross-inoculation experiments that several strains of the organism exist. Based upon trials made by various investigators the nodule organisms are separable into at least nine groups with reference to their power of infection of the various leguminous plants. Thus in one group fall the organisms from all the true clovers, species of *Trifolium;* in a second those from broad bean, peas, vetches, sweet pea, etc.; in a third those of species of *Phaseolus;* while those from soja bean, lupine and locust form each a separate group, no cross inoculations with these having been effected. It is also of great interest to find that on inoculation into animals a reaction occurs, agglutinins being produced which are

specific for the groups as determined by cross-inoculation. By cultural characteristics also the organisms from different legumes show marked differentiation. Three distinct groups can be made with reference to the rate of growth on artificial media, stickiness of the culture and opacity of the colonies. All these facts form perhaps a legitimate basis for the belief that distinct species exist among the nodule-producing bacteria. In numerous other characteristics, however, these organisms are so much alike, and as a whole they differ so widely from any other species of bacteria, that it seems more consistent to regard the adapted forms as varieties of the single species *Pseudomonas radicicola*.

Symbiotic nitrogen fixation has been found to occur in plants other than those of the *Leguminosae;* glands in the leaves of species of the *Rubiaceae* and *Myrsinaceae*, which were formerly believed to contain protein crystals, have been shown in reality to consist of colonies of bacteria living symbiotically with the plant cells, receiving their necessary supply of carbohydrates and salts from the surrounding green tissue of the leaves, and in return giving up their nitrogenous by-products to the plant. These organisms have been shown to fix atmospheric nitrogen when grown in artificial culture solutions devoid of any form of combined nitrogen. Their relationship, if any exist, to *Pseudomonas radicicola* has not yet been determined. These bacterial glands have been found in a number of plants, including *Pavetta, Psychotria, Kraussia* and *Ardisia*, and seem to be as closely wrapped up with the well-being of the plants as are the root nodules of the *Leguminosae;* the organisms are present in the slime between the young leaves before the opening of the leaf buds, and have been found in the seed between the scutellum and the embryo. Their introduction to the seed takes place at the time of fertilization, the pollen tube conveying them from the stigma to the ovule. The infection of the leaves occurs immediately after the opening of the buds, the ordinary water pores of the leaf usually functioning as the ports of entry. In the cases of *Pavetta* and *Psychotria*, however, where the glands appear on the lamina of the leaf, a special stoma has been described as an extraordinary adaptation of the plant for the reception of the bacteria. This pore is of exceptional size as compared with the ordinary stomata of the leaf, and is said to be filled in by growth of the surrounding tissue after its function has been fulfilled.

The benefit derived by the host plants from the presence of their guests has been clearly demonstrated by seedlings raised from bacteria-free seed—obtained by careful hot-water treatment of the seed—in sterile and inoculated sand cultures fertilized with potash and phosphorus but no nitrogen compounds. The plants grown in the inoculated cultures flourished and possessed typically green leaves, while those in the sterile sand showed all the signs of nitrogen starvation and soon died off.

Cellulose Fermentation.—The classical investigations of Omelianski showed that the cellulose of plant remains was decomposed under anaerobic conditions giving rise to marsh gas and hydrogen. This knowledge, however, does not help towards an explanation of the rapid destruction of plant residues in ordinary cultivated soils where conditions are mainly aerobic. It is well recognized that the looser the soil the more rapid is the destruction of carbohydrate material. It is generally supposed that fungi play an important part in these processes and many species of moulds and actinomyces have been shown to possess the power of attacking cellulose. The American workers have invented cellulose media upon which bacteria can be cultivated, and have succeeded in isolating several species, *Bacillus rossica, B. Amylolyticus, Bacterium flavigena* and some fifteen others which are capable of using pure cellulose as their only source of carbon. All these organisms are morphologically and physiologically distinct from Omelianski's hydrogen and methane organisms and grow well on ordinary gelatine media. The most powerful oxidizer of cellulose, however, is an organism discovered at Rothamsted in 1919. It is a peculiar organism exhibiting two distinct morphological characters at different stages in its life history, a long sinuous thread-like form and a large round "sporoid" form; it seems rather to be related to the spirochaetes than to the true bacteria and has received the name *Spirochaeta cytophaga*. It is an obligate aerobe and rapidly attacks cellulose, though it has no power of fermenting other carbohydrates; in fact, the presence of sugars, especially of the reducing sugars, strongly inhibits its action upon cellulose. Like the nitrifying bacteria it cannot be cultivated upon ordinary nutrient media containing proteins, 0·25% of peptone being sufficient to prevent growth. The products of decomposition of cellulose consist of a mucilaginous substance, small quantities of fatty acids and a yellow pigment allied to carotin. The discovery of this organism helped materially towards the production of an artificial substitute for farmyard manure, a great achievement in these days when motor traction has so reduced the available supply of this universal fertilizer. Moreover, the substitute has a considerable advantage over the natural product since the carbon-nitrogen ratio can be perfectly controlled.

Sulphur and Phosphorus Cycles.—Considerable attention has recently been paid to the conversion of the sulphur and phosphorus present in the proteins of plant and animal residues in the soil; by series of bacterial reactions, forming complete cycles, these elements pass from their combination in the protein molecule into the forms of sulphates and phosphates, and so become taken up and, once more, elaborated into the organic constitution of the plant. It has long been assumed that the supply of sulphates in all soils was sufficient for the optimum growth of crops. This assumption was based upon the low sulphur content of plant ash; recent investigations have shown, however, that as much as 90% of the sulphur of the plant may be lost in the process of ignition. The amount of sulphur removed by the crop from the soil is now a factor to be considered, and it has been shown experimentally that sulphur may become the limiting factor for crop production.

Further, the sulphur and phosphorus relations in the soil are considered to be interrelated to the extent that the insoluble rock phosphate is rendered soluble by the action of sulphuric acid produced in the oxidation by bacteria of the hydrogen sulphide from decomposing proteins. Pot experiments have shown that the application of sulphur as a fertilizer together with rock phosphate tends to increase the availability of the phosphate: the evidence at present, however, is insufficient to show whether any material profit is to be gained by this method of fertilization.

Sewage Disposal.—The purification of sewage by the aerobic bacteria which are normally contained in it is so slow, requiring many days for completion, that sewage disposal by this means alone has long been regarded as impracticable. A method of hastening the process was, however, discovered in 1913, and since 1916 the "Activated Sludge Process" has actually been in successful operation. When sewage is well aerated the colloidal suspended matter gradually disappears, being acted upon by aerobic bacteria, and gives place to a granular brown mass which rapidly settles, leaving a clear solution of the inorganic salts, such as chlorides and nitrates, with only quite small amounts of soluble organic matter. It was discovered that this brown sediment added to a fresh supply of sewage and aerated by a blast of very fine air bubbles considerably hastens the oxidation process. On repetition, each increase in the amount of the sediment in relation to the volume of sewage is accompanied by an increase in the rate of oxidation, so that, when the relative amount of sediment approaches 30% of the total volume, oxidation is complete in the space of a few hours. This brown sediment forms the so-called "activated sludge," and consists very largely of a mass of living organisms, bacteria and protozoa.

In practice two tanks are employed: (1) the aeration tank in which the sewage and activated sludge are blown with air forced through porous material so that it reaches the sewage in a finely divided state, and (2) the settling tank in which the sludge is deposited and from which an effluent requiring no filtration is run away. Any excess of sludge over and above that required to maintain the necessary quantity of 25% to 30% in the aeration tank is spread out to dry by evaporation and forms a valuable soil fertilizer.

The percentage of nitrogen in the activated sludge is considerably higher than that of the sludge from the sedimentation and septic tanks of the older and more usually employed method of sewage treatment. The results obtained from the activated sludge process in operation at Manchester show a yield of nitrogen per annum approximately equal to the total faecal nitrogen of the sewage treated, whereas in the older method much of this and all the urine nitrogen passes away in the effluent in the form of nitrates.

It has been stated that fixation of atmospheric nitrogen actually occurs in the process; from what is now known of the energy relations of the nitrogen-fixing bacteria, however, any considerable amount of nitrogen fixation in a medium where the quantity of soluble nitrogenous compounds is large in relation to the quantity of carbohydrate material seems very doubtful. It is more probable that the conservation of nitrogen results from the fixation of ammonia which in the older process of sewage disposal becomes converted into soluble nitrates.

As at present produced the amount of nitrogen in the dry sludge is about seven per cent. If by any means this can be increased to about 10% and if economical methods of drying the sludge can be found there is a great commercial future for the process. As it is, around Worcester, England, where by the activated sludge process something like a million gallons of sewage are treated daily, the fruit growers take away the sludge in a semi-dry condition and pay about 30s. a ton for it as it lies on the works.

Bacteriosis in Plants.—The study of bacteria in relation to plant diseases may be said to have been in its infancy in 1910. At that time—mainly through the researches of American bacteriologists—it had been shown that bacteria could enter healthy plants through wounds and stomata and produce epidemics of disease so serious in nature that the crops over wide areas were partially, and in some instances entirely, destroyed. The subsequent decade saw considerable activity in the field of plant pathology, and the pathogenicity of certain bacteria for plants has been fully established. In fact the number of species of bacteria now known to produce disease in plants is rapidly approaching that of the human pathogenes.

In comparing the disease-producing organisms in animals and plants one finds bacilli freely represented in both groups, but whereas the coccoid types, *Streptococcus, Micrococcus* and *Staphylococcus*, are frequently responsible for disease in animals, they have so far never been found to be associated with a disease in plants; on the other hand the genus *Pseudomonas* of Migula is strongly represented amongst the plant pathogenes while having no place, so far as is known, amongst the organisms pathogenic for

man and animals. No explanation for these interesting morphological differences has hitherto been advanced, and if any significance is to be attached to them it has yet to be discovered.

Exactly what it is that constitutes virulence in an organism and makes the distinction between parasitic and saprophytic forms is entirely unknown. One naturally asks whether an organism may possess virulence for both plants and animals: so far as experience goes this seems not to be the case; one may perhaps as the result of eating bacterially diseased fruits experience a temporary disturbance of the alimentary system, but nothing of a more serious nature need be feared. On the face of it such a phenomenon as a general occurrence would seem to be unlikely from the fact that the reaction of the medium in the two cases is very different; an organism which is favoured by the alkalinity of the animal serum can hardly be expected to grow strongly in the sap of a plant where the reaction is often strongly acid, and *vice versa*. On the injection of plant parasites into laboratory animals nothing more than a slight local disturbance—an abscess—results or occasionally the animal may show a disinclination to move and take food, a malaise for a brief period from which it quickly recovers. In the serum of such inoculated animals antibodies, specific agglutinins, are produced but this probably has nothing whatever to do with virulence since it follows also upon the injection of the common saprophytes.

The effects of bacteria upon the attacked plant are by no means so helpful towards a diagnosis of the disease as are the effects of bacteria upon the human being. The specific symptoms of disease in man by which the general practitioner is enabled to diagnose his case with more or less certainty, although he may have only a rudimentary knowledge of bacteriological technique, have no counterpart in the diseases of plants. The plant pathologist must first isolate and identify the causal organism, often a task of considerable difficulty, before he can arrive at a true diagnosis, the symptoms of disease produced by a number of different organisms being almost exactly similar. According to these group symptoms the bacterial diseases of plants may be divided into four main types, namely: *Soft Rots*, *Wilts*, *Intumescences* and *Local Lesions*.

Soft Rots.—The plants most attacked by rot-producing organisms are the root vegetables and potatoes. A certain amount of disease may occur while the plants are still in the ground, but the greatest losses take place during storage of the roots through winter. The rot results through the solution of the cementing substance, the middle lamella, which holds the cells of the plant tissue together just as mortar holds together the bricks in a building. This cementing substance consists of pectin material and its solution is effected through the agency of an enzyme, a pectinase, produced by the bacteria. The removal of this substance causes the tissue to lose all coherence and the cells to become reduced to a wet pulpy mass. Diseases of this type are the " White Rot " of turnips, the " Soft Rot " of carrots and other vegetables, the " Heart Rot " of celery, and the " Blackleg " of potatoes.

Wilts.—A number of very destructive diseases is included under this head. The symptoms are almost identical in all cases and are the result of the blocking up of the conducting system of the plant by bacterial growth in the vessels, so that those parts of the plant, whose natural supply of watery sap is thereby cut off, die from wilting, and become the prey of all kinds of bacteria from the soil and air, and finally either dry up or become reduced to a wet rotting mass. Other symptoms are striping of the leaves, a general dwarfing of the attacked plants, and a one-sided growth of the plants resulting from a one-sided localization of the infection. The striping of the leaves is due to pigments, either in the bacteria themselves or in the wood of the invaded vessels, making the course of these vessels apparent from the outside as streaks usually of a yellow, red, or brown colour.

Many of these wilts are caused by organisms which are extraordinarily similar in many of their characters. They belong to the genus *Pseudomonas*, are strongly yellow in colour and are indistinguishable under the microscope. They might be considered to be only varying strains of one and the same species except that they show constant differences in degree of pigmentation and in certain of their physiological characters; moreover they seem to be quite specific for the diseases in the plants or orders of plants in which they have been found, and all attempts to produce disease in one kind of host by inoculation with the specific organism of disease in another kind have so far been unsuccessful.

Included in this group of diseases are the very troublesome " Black Rot " of cabbage and other members of the family *Brassica;* Wakker's disease of hyacinths, which has been responsible for the entire disappearance of some of the most beautiful varieties of hyacinths from the beds of the Netherlands with serious financial loss to the Dutch growers; and a disease of sugar-cane known as Cobb's disease which produces heavy losses in seedling canes and also much difficulty and loss in extraction of the sugar by reason of the gummy slime which the bacteria produce, causing trouble in the crushing machinery and in the evaporating pans. Other serious wilt diseases are the wilt of cucumbers, the wilt of tomatoes, potatoes and other solanaceous plants, including tobacco whose cultivation in parts of Malay and other districts has had to be entirely abandoned as the result of this disease.

Intumescence Diseases.—Here the disease takes the form of large warty or pseudo-cancerous growths on the stems and leaves of the attacked plant caused by hypertrophy of the cortical tissues and mesophyll under the irritating stimulus of the presence of the invading organism. Crown Gall, a destructive disease of roses, grapevines, hops and a large number of other hosts, belongs here. In this case the trouble is largely confined to the crown of the root where it extends from year to year, eventually growing to such a size that death of the tree results through destruction of the conducting tissue of the root. Another disease of this type is the Olive Knot, a well-known pest wherever olives are in cultivation.

Local Lesions.—Local lesions or cankers result through destruction of the external tissues of plants in localized areas upon the stems, leaves and fruits. Stripe disease of tomatoes is well known to growers in Great Britain; the Citrus canker is a serious disease in S. Africa and S. Florida, and in the tropics generally Leaf Spot diseases of beans and of cotton have been shown to be caused by bacterial parasites.

Control Measures.—At present there is no means of control for bacterial diseases in plants which can be of general application. Obviously the prophylactic and curative methods of injection so successfully used against disease in animals cannot be of use for plants. The use of sprays which are often most effective against fungal diseases of plants is of no avail against the bacterial ones. Sterilization of the soil might be of service against such parasites as are infective of the plant through the soil, but it is clear that, in order to kill the parasitic form, one would at the same time necessarily interfere with the normal soil flora upon the functions of which the fertility of the soil depends.

In certain instances where the disease is carried by some biting insect, attacks upon this carrier have resulted in more or less successful control. A case in point is that of the wilt of cucumbers, where the organism is introduced on the mandibles of a beetle. In this case it is found that the beetle has a special predilection for the wild squash, and by growing these in drills between the rows of cucumbers almost all the beetles can be collected upon them, where they can be periodically annihilated by spraying with kerosene. Another means of control is found in the manurial treatment of the soil whereby a more hardy and resistant plant is produced. In this way by the increase of potash it has been possible to effect a considerable reduction of the Stripe disease in tomatoes. The rotation of crops, so that several years elapse before a crop which has been diseased is again grown on the infected soil, is for the majority of bacterial diseases the only means of control known at the present time. In this way the parasite, not finding its particular host for some time, may die out or may become so altered physiologically as no longer to possess the power of attack upon the plant.

II. MEDICAL BACTERIOLOGY

It has been more and more recognized by the epidemiologist that one of the chief structural units in the bridge which connects one outbreak of a disease with another is the carrier. By the term " carrier " is meant an individual who, though healthy and thus unsuspected of infectivity, still harbours in his body pathogenic bacteria which, passed in the various excretions, constitute, when given favouring circumstances, a danger to those about him. These favouring circumstances may be withheld for long periods, but the individual, on the other hand, may continue to conserve and distribute the microörganisms for still longer periods—even many years.

Disease Carriers.—A certain number of bacteria pathogenic to man find carriers among animals, for instance the virus of Malta fever, which multiplies and is distributed in the milk of infected goats, but mainly man is himself responsible.

The carrier may be a person who has survived an attack of the disease in question and failed to rid himself of the causative organisms, which, lodging themselves in the respiratory, genito-urinary or intestinal tract, continue an existence much as do the saprophytic organisms normally found in those regions. He may, on the other hand, be an individual who entertains the bacterium without ever having displayed any symptoms of the disease. A chain of such carriers, recording no history of illness, but passing on the virus in secret, as it were, would be the explanation of sporadic cases, say, of cerebrospinal meningitis, occurring in non-epidemic times, at

widely distant and apparently unrelated places. In the same way, the seeds of a disease may be conserved over long periods from one epidemic to another.

That the carrying of pathogenic bacteria by either man or animals, together with the opportunity of their transmission to others, does not altogether explain the spread of disease is certain. A loss of virulence on the part of the virus or an acquisition of immunity by the population, or both of these occurrences, must be assumed to explain the gradual spontaneous termination of an outbreak, and, similarly, the converse of those phenomena must be regarded as playing a large part in the recrudescence of an epidemic.

The laws governing the loss or gain of virulence by bacteria are very imperfectly understood; even in the laboratory pathogenicity is largely beyond control; elsewhere it is entirely so. The two other factors concerned in the spread of disease are less elusive. Even though the carrier state is one which has so far shown itself recalcitrant to treatment, carriers can be, if circumstances warrant such a drastic step, segregated, kept under observation, and finally recommended to adopt a course of life not likely to favour infection of others. To hasten or forestall the immunity assumed to occur in a community during the course of an epidemic is the object of prophylactic inoculation, a procedure of which the success has been further demonstrated during the World War.

Prophylactic Inoculation.—The compound anti-enteric vaccine, which includes all three typhoidal germs, *B. typhosus*, *B. paratyphosus A and B*, was universally employed in the British armies and was attended by excellent results, as witnessed by the following statistics.

Typhoid cases in the British Expeditionary Forces in France up to May 1915 numbered 827. It was found that the incidence was 14 times and the mortality 42 times greater among the uninoculated than among the inoculated; up to August 1916 508 uninoculated had a case mortality of 23·4 %, while 906 inoculated had one of 5·2 %. Similar good results attended the use of anti-typhoid vaccine in the armies of other belligerents. It clearly reduced the total number of cases and lowered the mortality rate. Only in Germany was doubt cast by any appreciable number of scientific workers on the efficacy of prophylactic inoculation. A small body of opinion there considers that only by the use of a living virus, as in smallpox vaccination, can a reasonable immunity be conferred. It has been suggested by their critics that the Kolle vaccine, which is used in Germany, is of inferior immunising power, and certain pre-war statistics, comparing the use of this vaccine with one prepared by Vincent's method, bear this criticism out.

Other prophylactic vaccines, the use of which has been attended more or less definitely by success, are those directed against cholera, plague, pneumonia, cerebrospinal meningitis and influenza. Tentatively used, because of its great toxicity, is anti-dysentery vaccine.

Vaccine Therapy.—Other therapeutic employment of bacterial vaccines has been extensively adopted and has, according to some workers, justified itself in such widely different diseases as furunculosis, rheumatoid arthritis and whooping-cough. Much work without, unfortunately, corresponding success continues to be done with vaccine therapy in tuberculosis. It was hoped at one time that the administration of vaccines might be controlled by observations of the opsonic index, made during treatment, but the method has been discarded as not capable of furnishing a reliable guide to dosage, as was expected of it.

Serum Therapy.—Treatment by inoculation with serum specific for the disease in question has made notable advances. Besides those long in use in diphtheria, tetanus and streptococcus infections, sera capable of neutralizing the toxins produced by *B. welchii*, *B. oedematiens* and *V. septique*, all these gas-gangrene bacilli, are now prepared. The efficiency of anti-meningococcus serum has been greatly increased by the recently acquired knowledge of the physiology of the meningococcus and by improvements in the manufacture of anti-toxin. Thus it was possible, by the use of more effective sera together with more rapid diagnosis generally, to lower the death-rate for cerebrospinal meningitis in the home forces from 65 % in 1914 to 35½ % in 1918, and even to less than 10 % where the infection was due to that strain of the meningococcus known as Type I.; it is against this type that the most potent anti-toxin is preparable. Other sera the use of which has been attended by favourable results are those directed against dysentery and pneumonia.

Anaphylaxis.—In connexion with the administration of animal sera, the phenomenon of anaphylaxis has to be recognized. In animals this condition results after repeated inoculation with a protein foreign to the animal injected. A guinea-pig, for instance, if inoculated with even a very small quantity of, say, horse serum and then after at least five days reinoculated with the *same* type of protein, can in some cases suffer so severely that death ensues within a few minutes, and this although the total amount of protein administered on both occasions is very much less than that which could with perfect safety have been given on the first occasion. The first inoculation is regarded as rendering the animal "sensitive" to the particular protein employed and may, for an animal like a guinea-pig, be as little as 0·00005 of a milligramme. The second inoculation of 0·1 to 0·5 of a milligramme occasions the anaphylactic shock, which consists for the main part of convulsions, paralysis and cessation of respiration. The causative agent has been considered to be a poison formed by the union of the antibodies, produced in the animal by the first inoculation, with the antigen (the protein) inoculated on the second occasion and has been called anaphylatoxin. A surprising feature is that, no matter what protein be employed, the symptoms are in all cases similar. It is for this reason that other investigators have thought anaphylaxis to be not a toxic but a colloidal phenomenon, in which after the second inoculation an extremely minute precipitation, a gel phase, occurs in the body, occasioning in the lungs mechanical interference with oxygen absorption.

In man anaphylaxis is not so pronounced as in some animals, for instance rabbits and guinea-pigs, yet the danger is sufficiently grave to demand special care during serum treatment.

It has been found in animal experiments that if the second inoculation of protein is survived, the anaphylactic condition disappears. In serum therapy, therefore, if any anaphylaxis is to be feared, a very small "desensitizing" inoculation is given before proceeding to the injection of the full amount. The anaphylactic state is met with in persons who have, on some previous occasion, had serum administered to them, or, more usually, it is encountered as a natural condition, as for instance in those individuals who show susceptibility to some particular foodstuff, such as white of egg.

Anaerobes and Gas Gangrene.—A group of bacteria which the World War threw into great prominence is that of the anaerobes. A wide divergence exists among microörganisms as to the oxygen pressure under which growth is possible. The anaerobes require that oxygen be absent, or present in but minimal quantities, in their environment. The group is found widespread in nature; its chief breeding-ground being the intestinal tract of man and animals, distribution proceeds for the most part along with the manuring of the fields.

The importance of the group from a human point of view lies in the high toxicity possessed by several of its members. Its more special importance during the war lay in the fact that wounds inflicted by explosive force are usually extensive and earth-soiled, this in such highly cultivated lands as those of Flanders giving an opportunity for infection by anaerobes and for the subsequent development of the very fatal gas gangrene that was, particularly in the first months of the war, such a frequent wound complication.

Knowledge of the anaerobes has been, until the last few years of intenser French, English and American work, in a chaotic condition, only *B. botulinus*, which occasions food-poisoning, and the bacillus of tetanus having been at all accurately studied and described. Of the remaining anaerobes little was known with certainty; accounts were contradictory owing to non-recognition of the fact that the cultures with which work was carried out were not pure. In this way, besides there being great confusion in nomenclature, the group acquired an undeserved reputation for remarkable variability; it was recorded how one species melted into another with the mere alteration of the media on which it was grown and the result was ascribed to an inconstancy of species. In reality, it was a second strain, long dormant in the impure culture, which was now, owing to a more congenial environment, able to assert itself.

The usual bacteriological methods for the establishment of pure cultures which hold good in the case of aerobes are unreliable when applied to the anaerobes, which appear to possess a special property of not readily growing, unless associated in some numbers. For this reason, the anaerobic cultures which "take" are far more likely to be impure, and the concealed impurity may pass undetected through a whole series of sub-cultures.

A more refined technique and a more meticulous criticism of results proved necessary and were applied during later investigations.

In the group of spore-bearing anaerobic organisms concerned with wound infections and apart from *B. tetanus* already well studied, in spite of the fact that it also existed mainly in impure culture in the laboratories, three outstanding pathogenic species have been set up:—

(1) *B. welchii*, the most frequently found of the gas-gangrene bacilli, previously described under a variety of names and in various conditions of impurity as *B. aerogenes capsulatus*, *B. phlegmonis emphysematosae*, *B. perfringens*, *B. enteritidis sporogenes*; (2) *Vibrion septique* (Pasteur), the *B. oedematis maligni* of Koch, and (3) *B. oedematiens*, a highly toxic organism discovered by Weinberg and Seguin in 1915.

For all three, potent antitoxic sera have been prepared and the treatment of cases has been greatly improved by their use. Certain slightly pathogenic anaerobes such as *B. histolyticus* are also concerned in the polymicrobic invasion of wounds, as well as a series of definitely non-pathogenic anaerobes, like *B. sporogenes*. Some of these may symbiotically assist infection; others appear only in the rôles of contaminating organisms, taking no part in the morbid processes.

Epidemic Influenza.—To our knowledge of the aetiology of influenza the last world-wide epidemic of 1918, with its enormous incidence and with its appalling mortality returns, such as that of six millions for India alone, has brought but an increase of uncertainty. Discovered by Pfeiffer in 1892 the *B. influenzae* was, up till 1918, widely accepted as the cause of that disease. But the failure, during the last pandemic, of a large number of bacteriologists

to isolate the bacillus from a considerable proportion of the cases investigated, together with the fact that the disease could not be experimentally passed on to either man or animals by inoculation with Pfeiffer's bacillus, caused a revolt from the orthodox belief. It is considered by many that the primary aetiological factor still remains undiscovered and that the *B. influenzae*, like the *Streptococcus* and the *Pneumococcus* (the three pathogenic microörganisms most usually found associated with the disease), is but a secondary invader of the tissues, and even though of such malignancy as to be frequently the occasion of the fatal termination, still not the original *causa causans*. Owing to their negative findings, a large number of bacteriologists have concluded that this must be placed in the ever-growing ranks of the filtrable invisible viruses, organisms so minute that even with the aid of the ultra-microscope they are not or barely to be seen; of so diminutive a size that they are capable of passing through the pores of even the finer porcelain filters. An accepted instance of such a deposition of an organism from the position of causative agent to that of a mere secondary invader may be found in the case of *B. suipestifer* in the disease hog cholera. The true virus here has been demonstrated to be a filter-passer.

From many parts of the world came reports of the proof of such theories of a filtrable virus in influenza, but in no case have they stood the test of criticism. With regard to the tiny globoid bodies shown in the filtered fluids, no evidence of their true influenzal nature from an infective point of view was forthcoming. They have been considered to be inanimate particles of disintegrating protein or even ordinary contaminating bacteria gaining access to the culture tubes through a faulty technique.

Those investigators who resent the attack on the orthodox belief in the *B. influenzae* as an aetiological factor point out that not all workers failed to find that organism in their cases; that those employing more satisfactory media for the growth of the bacillus were able to isolate it in as many as 90%. They further point out that an illness recognizable as influenza has not so far been transferable to ordinary experimental animals. That man is not infected by inoculations with living *B. influenzae* is, they hold, discounted by the observation that it has not been possible voluntarily to transmit the disease from one person to another, even by such drastic methods as the swabbing of the mucous membranes with the inflammatory secretions taken from the eyes, nose and throat of pronounced cases.

This paradoxical indication of a low infectivity of influenza is qualified by the fact that the experiments have been carried out during and subsequent to the pandemic, when persons chosen for the experiment as normal, because of their not having succumbed to an attack of the disease, may be regarded on those very grounds as possessing a considerable degree of natural immunity, and therefore as not being acceptable as normal at all. More recently, experimental infection of both monkeys and man with influenza bacilli and the production of acute respiratory disease have been demonstrated, but the identity of the illness evoked with that of epidemic influenza is far from established. The whole question of the aetiology of influenza is still *sub judice*.

A New Paratyphoid.—Early in the war, in a number of the armies engaged in the Near East, an illness was noticed which, although it corresponded clinically in many ways with enteric, did not yield a virus agreeing with any of the three well-known organisms of that group of diseases—*B. typhosus, B. paratyphosus A or B*—though culturally it was identical with the last-named. The bacillus that was isolated by Hirschfeld from cases occurring in the Serbian army was called by him *B. paratyphosus C*, and included in the anti-enteric vaccine used in the Serbian forces. Neukirch, recording recognition of it earlier on the Turkish front, gave it the name of *B. Erzindjan*. As the organism agrees culturally with and is serologically related to *B. paratyphosus B*, it has been suggested by others that it should, for simplicity's sake, be regarded as one of the many paratyphoid B types. Some workers have insisted on the identity of this so-called paratyphoid C with the bacillus found in pigs suffering from swine fever and called variously *B. suipestifer, B. of hog cholera*, and *B. Voldagsen*, but, though the relationship is very close, identity does not seem to have been proved. This newly recognized type of paratyphoid B, apparently in the main of Eastern habitat, has no doubt often in the past masqueraded as an atypical or inagglutinable paratyphoid bacillus.

Typhus Fever.—Another disease that sprang into special prominence during the war, and the aetiology of which has received considerable elucidation, is typhus. Nicolle and his collaborators first gave experimental proof of the transmission of typhus to monkeys by the body louse. In the case of man such laboratory demonstration has, however, because of the severity of the disease, been mainly accidental and therefore incomplete. But while there are other theories of supplementary means of infection, such as that it is air-borne or transmitted by droplet infection, evidence that the louse is the only carrier or communicator of typhus has accumulated to a great extent. The sole measure for the successful combating of an epidemic has been a de-lousing campaign. The effect of good ventilation in preventing infection spreading from patients in a ward, at first regarded as a proof of its air-borne nature, can now be explained by the fact that lowered temperatures are inimical to the activities of lice. In cool, well-ventilated rooms these vermin will refrain from leaving the bodies of their hosts, and should they be driven to do so by the high temperature of a very feverish case or the lowered one of a corpse, they will be handicapped in their search for a new host. Against the complicity of other insects, such as the flea and the bed-bug, there are the observations that typhus is contracted only after close contact, which for flea-borne diseases is not necessarily the case; while, did the bed-bug play a part in infection, typhus would be a house disease and not one transmitted for the main part through the agency of lice-ridden clothes.

In 1910 Ricketts and Wilder described very small bodies seen in the gut of lice taken from typhus patients. In 1916 Rocha Lima repeated the observation. He regarded them as protozoal in nature and classified them as chlamydozoa. The chlamydozoa are organisms more minute than bacteria, consisting at one stage of but a speck of chromatin with no cytoplasm or membrane of any kind. At some period of their life-cycle they are filtrable. The viruses of rabies, poliomyelitis, scarlet fever and vaccinia have among others been regarded as belonging to the chlamydozoa. The form seen in typhus lice was called by Rocha Lima *Rickettsia prowazeki*, to commemorate two workers who had succumbed to typhus infection during their investigations; Ricketts being also, in 1909, the first to describe bodies of this nature in the tick which transmits the disease known as Rocky Mountain fever. The aetiological relationship of these bodies to typhus is being generally recognized. The criticism that similar bodies have been found where no typhus existed has been countered by the discovery that a different species, the *Rickettsia quintana*, is associated with the disease trench fever, and the assumption that, as there are a variety of *Rickettsia*, some may well be apathogenic for man. Belief in the causative nature of such bacilli as that of *Plotz* and the *Proteus X 19* of Weil and Felix now finds little support. Indeed, when lice are fed with the latter organism, they die within the period it takes a louse to become infective after it has had access to a typhus patient. The defenders of a filtrable virus as the infecting agent are met by the fact that some forms of *Rickettsia* have been described of so small a size that their passage through a filter fine enough to retain bacteria would be possible.

Trench Fever.—In 1916 Töpfer recorded the occurrence of *Rickettsia* bodies in the blood of and in lice taken from individuals suffering from what has in different countries been called trench or Volhynian fever. The justification for the association of this *Rickettsia quintana* or *Volhynia* with the febrile disease rests on much the same kind of evidence as that furnished in the case of typhus; but here experimental work on man has been possible, and Arkwright, Bacot and Duncan have definitely proved the infectivity of the *Rickettsia*-containing lice and their excreta for human beings.

Yellow Fever and Infectious Jaundice.—A great deal of enlightening work was carried out on yellow fever during 1919-21 by the Japanese research worker Noguchi, of the Rockefeller Institute. Previous to his investigations most of our knowledge of the aetiological factors in this most dreaded of tropical diseases rested on the courageous work with its attendant loss of human life performed by the American Yellow Fever Commission in 1900. It was then established that yellow fever was an insect-borne disease, the vector being the mosquito *Stegomyia calopus*. Many other data, concerning the incubation period of the disease and the life-cycle of the virus, which was shown to be filtrable, were also established. But the causal agent was neither isolated nor seen. It remained for Noguchi to detect in yellow-fever cases a spirochaete, an organism of similar nature to the specific agent of syphilis, a protozoön, and to prove, short of reproduction of the disease in man, its aetiological relationship to yellow fever. This organism he named *Leptospira icteroides*. He found it to be very closely related to, though not identical with, the leptospira discovered independently by Inada and Ido in Japan and by Uhlenhut and Fromme in Germany in cases of infective jaundice or Weil's disease. This latter organism has for hosts both rats and mice, and has been named *L. icterohaemorrhagiae*; an anti-serum is made with the leptospira of infectious jaundice and possesses considerable curative value. Noguchi's reports on anti-yellow fever inoculation are only just beginning to appear but already show favourable results.

Wassermann Test.—Among laboratory diagnostic methods of a serological character, the Wassermann test for the detection of syphilitic infection still maintains its position of prominence. The reaction, which is a complicated one, declares itself as positive or negative by the power the patient's serum has or has not of going into combination with guinea-pig complement and an extract of animal tissues. This was at first regarded as an immunity reaction, involving the usual antigen, anti-body and complement, with the *Spirochaeta pallida* (the virus of syphilis) acting as antigen. But it is now known that that organism does not play a part at all in the test, which is considered to be an interaction between lipoid bodies (in the tissue extract), anti-lipoid bodies (present in syphilitic sera owing to the abnormal production of lipoids during the course of the disease) and complement (guinea-pig serum). Many modifications of the original Wassermann reaction are in use, mainly characterized by increased complexity of technique, but the new diagnostic method of Sachs and Georgi is comparatively simple, consisting merely of interaction between the patient's serum and a lipoid solution; it is apparently of satisfactory reliability.

Agglutination Test.—A serological test which has undergone some development in recent years is that of agglutination. It has become more necessary to distinguish between specific and group agglutination. When an agglutinating serum has been prepared by inoculating an animal with one species of bacteria, it is found that the serum is capable, not only of agglutinating that species to a high degree (specific agglutination), but also frequently of agglutinating other closely related species (group or co-agglutination), and this sometimes to practically the same extent as it does the homologous species. Further, it has been observed that an organism isolated from an individual infected with some other quite alien, bacterial species will have acquired, more or less temporarily, the property of agglutinating with serum specific to that alien infecting species. This is called paragglutination. Perhaps the most striking case of paragglutination is that of a certain strain of *B. proteus*, named by its discoverers *X19*, and isolated by them from cases of typhus. Here an organism, well known as an agent of bacterial decomposition and of some virulence for the human body, though productive of no symptoms comparable with those of typhus and believed not to participate in that disease at all, has acquired the property of agglutinating with the serum of individuals who have contracted typhus. This it does to so marked a degree that the paragglutination has actually been used as a means of diagnosing the illness, far removed from one another though *B. proteus* and the causal agent of typhus are in the scale of living organisms. And in this case, the paragglutinating character has been seen to be more than a temporary acquisition.

Absorption Test.—To distinguish between specific and non-specific or group agglutination, a modification of the agglutination test is employed—the absorption test. It is found that, after complete absorption of a serum with its own specific species, all agglutinins have been removed. When a co-agglutinating species is employed only the group agglutinins will be absorbed, the specific agglutinins remaining intact. By this means it has been possible to discriminate between closely related strains and to divide species into a variety of types. This has been notably the case with the pneumococcus, the meningococcus, the dysentery and paratyphoid B groups. The recognition of the existence of different types of pneumococci and meningococci has proved of great importance for diagnostic, prophylactic and therapeutic reasons. In the case of prophylactic inoculation against pneumonia, as carried out so extensively by Lister on South African miners, it was seen to be very essential that the types predominant should be outstandingly represented in the vaccine used. In the serum therapy of both pneumonia and cerebrospinal meningitis cases it is necessary for the best results that the type of pneumococcus and meningococcus concerned should be known and a corresponding anti-serum administered. When dealing with *B. tetanus*, on the other hand, the importance of distinguishing between the various agglutinatory and absorptive types does not maintain; an identical toxic element appears to be common to them all, so that one anti-toxin serves for whatever type may be responsible for the infection.

Schick Test.—Valuable aid in combating diphtheria epidemics is afforded by the Schick test. This supplies a criterion of the immunity an individual possesses against infection by the diphtheria bacillus and is carried out by the injection of a small quantity of diphtheria toxin into the skin of the person tested. If the individual possesses immunity the toxin is neutralized and no reaction in the tissues takes place; if there is no immunity the toxin, by irritation of the skin, sets up a small inflammatory condition which is easily recognizable. The practical application of this measure lies in the possibility thus afforded of discovering, in, say, a school or other large body of people who are running the risk of diphtheria infection, which individuals possess no natural immunity and thus need safeguarding. The treatment, which may then be limited to those requiring it, consists of passive immunization with diphtheria anti-toxin, if protection is needed for but a short time; or, if active immunization, by injecting a mixture of toxin and anti-toxin, in which case the immunity acquired may be expected to last for one to two years. Those individuals who, without treatment, disclose by the Schick test a natural immunity are regarded as possessing it probably for life.

REFERENCES.—References to most of the work here detailed can be found only in the journals specially devoted to those subjects, the more important of these being:—*British Medical Journal; Lancet; Journal of Pathology and Bacteriology; Journal of Hygiene; Tropical Diseases Bulletin; Special Reports of the Medical Research Council; Journal of Experimental Medicine; Journal of Infectious Diseases; Journal of Medical Research; International Journal of Public Health; Annales de l'Institut Pasteur; Bulletin de l'Institut Pasteur; Zeitschrift für Hygiene und Infektionskrankheiten; Centralblatt für Bacteriologie.* Lehmann and Neumann's *Bakteriologische Diagnostik* (1920) contains many literature references, mainly European.

BADEN, FREE STATE OF (*see* 3.184).—The population of the Free State of Baden, Germany, was, according to the census of 1919, 2,208,503.

Political and Constitutional History.—Baden was, till the revolution of 1918, a constitutional monarchy; the sovereign bore the title of Grand Duke. The Diet (*Landtag*), which was composed of two Chambers, had indeed the right of legislation and of voting taxation, but the ministers were appointed by the Grand Duke at his own discretion. The government had always been conducted in a liberal spirit; Baden had in Germany the reputation of being the model of a diminutive Liberal country (*ein Liberales Musterländle*), though the population was preponderatingly Catholic. There was certainly a powerful Clerical minority in the second Chamber of the Diet. When at a general election there was a danger that a Clerical-Conservative majority would be elected, the two Liberal parties (the National Liberals and the Progressists) concluded an alliance for election purposes with the Social Democrats, thus constituting the so-called "grand *bloc*." The result was that the Social Democrats held a considerably different position in Baden from that which they occupied in the empire.[1] But in Baden, too, the line was drawn at allowing Socialists to become members of the Government. The Social Democratic party nevertheless endeavoured to place as few difficulties as possible in the path of the Government, and it did not, as elsewhere, vote against the budget. When the World War broke out in 1914, the leader of the Baden Social Democrats, Ludwig Frank, at once enlisted as a volunteer and fell in one of the earliest battles.

The Liberal sympathies of the Baden dynasty were maintained during the war. The heir to the throne, Prince Max of Baden, tried to exercise his influence in favour of a peace by understanding and of Liberal reforms in the internal policy of the empire. When in Oct. 1918 William II. at last decided to agree to the reform of the constitution by which the parliamentary form of government was introduced for the empire, Prince Max was appointed imperial chancellor. It was too late. He could not arrest the progress of the revolution. When the monarchy fell in the empire, it could not be maintained in Baden, although there was in this instance no reason for complaint on the score of misgovernment. On Nov. 10 the revolutionary Provisional Government was formed, containing representatives of the Social Democratic, the two Liberal parties and the Catholic Centre. On Nov. 22 the Grand Duke therefore definitely abdicated, with the assent of the heir to the throne, Prince Max.

The Provisional Government of Baden issued as early as Nov. 20 an ordinance by which elections were instituted for a National and Constituent Assembly.[2] This representative body met on Jan. 15 1919 and at once began to discuss the draft of the constitution which had been submitted to it by the Government. On May 21 1919 the new constitution was passed by the National Assembly. Baden was thus the first German state which put an end to the lawless revolutionary situation. The consequence, it is true, has been that the Baden constitution has in several points been nullified by the constitution of the Reich, which was enacted at a later date; for the independence of the German Territories, as the states united in the Reich are designated, was considerably curtailed by the constitution of the Reich of the year 1919. Nor is there any room in the constitutions of the Territories for provisions regarding the "Fundamental Rights of the People," since the constitution of the Reich has settled these Fundamental Rights.

Baden in 1921 was a republic with a democratic constitution. The powers of State were actually vested in the Diet (*Landtag*), which consists of a single Chamber. The Diet does not only possess the right of legislation, but it chooses the ministry and selects from among the ministers the minister-president. He has the title of "President of the State," but he is not the head of the state, but merely the person who presides over the ministry. The Diet can at any time dismiss the whole ministry or individual members

[1] *Reich* is translated "Empire" when it refers to the Hohenzollern régime; the German word *Reich* is retained when it refers to the German Federated Commonwealth established after the revolution.

[2] Each of the German states called its Constituent Assembly a "National" Assembly (*Nationalversammlung*).

of it. The franchise for the election to the Diet is possessed by all men and women who have completed their twentieth year. There must be a general election every four years. The dissolution of the Diet can be brought about before the end of the legislative period by a vote of the people. Laws can also be passed by a vote of the people, and that in two ways: a law which has been voted by the Diet can be submitted to the vote of the people by the Referendum, if the ministry so decides or if the people itself so demands; secondly, an appeal may be proposed by Popular Initiative. Laws involving an amendment of the constitution must always be submitted to a Popular Referendum. The constitution of Baden has thus a great resemblance to that of the Swiss Confederation; but there is the essential difference that in Baden the Government is dependent upon Parliament. (W. v. B.)

BADENI, KASIMIR, Count (1846–1909), Austrian statesman, was born Oct. 14 1846 at Surachovo in Galicia, his family being of Italian origin. He studied law and served some years in the Ministry of the Interior and from 1879 at Cracow as lieutenant of the governor of Galicia. He resigned the Government service in 1886, but two years later was appointed governor (*Statthalter*) of Galicia, where he ruled the Ruthenians with a strong hand. In Sept. 1895 he was appointed Austrian prime minister, and his attitude was at first satisfactory to the German-Austrians. In 1897, however, in order to gain the support of the Czechs for the new *Ausgleich* with Hungary, he made certain important concessions in respect of the official use of the Czech language in Bohemia. This was done by ordinance, without parliamentary sanction, and met with violent opposition from the German deputies, some of whom were imprisoned. The storm of indignation aroused among the German-Austrians by this policy, which led to imposing demonstrations in the streets of Vienna, led to Badeni's downfall on Nov. 28 1897. He died July 9 1909. (C. Br.)

BADOGLIO, PIETRO (1871–), Italian general, was born at Grazzano (Alessandria) Sept. 28 1871. He received his commission in the artillery, and thence passed to the general staff. During the Italo-Turkish War he served in Tripoli on the staff, receiving special promotion to major after the battle of Zanzur in June 1912. In the spring of 1915 he was promoted to lieutenant-colonel and on Italy's entry into the World War he held the post of sub-chief-of-staff of the II. Army under Gen. Frugoni. In quick succession he acted as chief-of-staff of the 4th Division, and commanded the 74th Infantry Regiment on Monte Sabotino. In July 1916 he received another step, and as colonel commanded the "Sabotino Sector." He planned and carried out the successful attack on Monte Sabotino which preceded the fall of Gorizia (Aug. 1916). For this success he was once more promoted. After serving as chief-of-staff of the VI. Corps and commanding the Cuneo Brigade, he became chief-of-staff of the so-called "Gorizia Zone" under Capello, with whom he remained when the command of the "Gorizia Zone" was extended to the whole II. Army. On the eve of that army's offensive in May 1917, Capello, dissatisfied with the artillery preparation in the sector of the II. Corps, obtained the appointment of Badoglio as interim commander of the corps (May 12). After the capture of Monte Kuk and Monte Vodice this appointment was confirmed, and he received another step of promotion. He commanded the II. Corps at the beginning of the August offensive but when the XXVII. Corps on the extreme left of the attack failed to make the progress expected he was sent to take over the corps. This time, however, the endeavour to make up for lost time was unavailing. At the battle of Caporetto, Badoglio commanded the same corps, the left wing of which was broken by Otto von Below's attack from the Tolmino bridgehead. On the reorganization of the Italian Supreme Command (Nov. 1917) he was appointed as one of the two sub-chiefs-of-staff then nominated, the other being Gen. Giardino. From Feb. 1918, on Giardino's transference to Versailles, Badoglio acted as sole sub-chief-of-staff under Diaz. He conducted the Armistice preliminaries at Villa Giusti, and signed the Armistice on behalf of Italy. In Nov. 1919 he was appointed to the rank of army general and from Diaz's resignation to Feb. 1921 he was chief of the general staff in succession to Diaz. Badoglio's rapid rise was explained by the qualities which he showed in a special degree: determination, energy, and thoroughness. These qualities, joined to a natural military instinct developed by much study and backed by a powerful ambition, marked him out early and brought him very quickly to the front. He was blamed in various quarters for his disposition of the XXVII. Corps before the Austro-German attack in Oct. 1917, but the Caporetto Commission of Inquiry rejected most of the criticisms made upon him.

BAEYER, JOHANN FRIEDRICH WILHELM ADOLF VON (1835–1917), German chemist (*see* 3.192), died at Munich Sept. 5 1917. Up to within a year of his death he continued in full active work as one of the best-known teachers in the world of organic chemistry.

BAGWELL, RICHARD (1840–1918), Irish historian, was born Dec. 9 1840, the eldest son of John Bagwell, M.P. for Clonmel from 1857 to 1874. Educated at Harrow and Christ Church, Oxford, he was afterwards called to the English bar, but never practised. As a large landowner in Tipperary he devoted constant and conscientious attention to local affairs, serving on all boards and committees until 1898 when, on the passing of the Local Government Act, his wide experience led to his appointment for five years as a special local government commissioner. In 1905 he became a commissioner for national education. As a historian his reputation rests mainly on his two works, *Ireland under the Tudors* (3 vols. 1885–90) and *Ireland under the Stuarts* (3 vols. 1909–16), which are monuments of careful research and wide learning. In recognition of his historical work he was given the hon. degree of Litt.D. by Dublin University in 1913 and that of D.Litt. by Oxford University in 1917. Mr. Bagwell was an uncompromising Unionist, and was well known as a speaker and writer for the cause. He died at Marlfield, Clonmel, Dec. 4 1918.

BAIRNSFATHER, BRUCE (1887–), English humorist, was born at Murree, India, July 9 1887, and was educated at the United Services College, Westward Ho. He became a civil engineer, and also had some military experience in a militia battalion of the Royal Warwickshire Regt. In 1914 he rejoined this regiment and went to France, serving there until 1916, when he obtained a War Office appointment. Bairnsfather's reputation as an artist was made by his black-and-white sketches of life in the trenches, which first appeared in *The Bystander*. His soldier characters became popular favourites, and a play, *The Better 'Ole* (1917), founded on the adventures of "Old Bill" and his friends, enjoyed a great success. Many of Bairnsfather's drawings were published in volumes entitled *Fragments from France*. He also produced *Bullets and Billets* (1916) and *From Mud to Mufti* (1919). In 1919 he started *Fragments*, a weekly comic paper.

BAKER, GEORGE PIERCE (1866–), American educationist, was born at Providence, R.I., April 4 1866. He graduated from Harvard in 1887 and taught English there as instructor, assistant professor and, from 1905, as professor. His courses dealing with the theory of the drama were highly successful, and his famous laboratory, known as the "47 Workshop," afforded practical training for his students, many of whom became well-known playwrights. In 1919 he was entrusted with the preparation of a pageant to commemorate the tercentenary of the landing of the Pilgrims at Plymouth in the State of Massachusetts. This pageant, "The Pilgrim Spirit," was presented accordingly at Plymouth in Aug. 1921.

His works include *Specimens of Argumentation* (1893); *Principles of Argumentation* (1895); *The Forms of Public Address* (1904); *The Development of Shakespeare as a Dramatist* (1907); *Some Unpublished Correspondence of David Garrick* (1907); *The Correspondence of Charles Dickens and Maria Beadnell* and *Dramatic Technique* (1919) and *Modern American Plays* (collected and edited with introduction, 1920).

BAKER, HERBERT (1862–), English architect, was born in 1862, and educated at Tonbridge school. He was articled to Arthur Baker, and later entered the office of Sir Ernest George, where he remained as assistant for some years. He studied at the R.A. schools, and in 1889 was awarded the

Ashpital prize of the R.I.B.A. In 1892 he left England for South Africa, and there, with Cecil Rhodes as his friend and patron, began the work of reviving the old traditions of the architecture and craftsmanship of the colony. For Rhodes he built Groote Schuur, afterwards the permanent home of the prime ministers of South Africa, and also a house which the same patron built on Table Mountain for his friend Rudyard Kipling. Cecil Rhodes sent him on a tour of travel and study in Egypt and southern Europe, and, as a recognition of this generosity and the value of such an opportunity to a young architect, Baker founded the South African Scholarship at the British School in Rome. After the death of Rhodes he carried out the great Memorial on the slopes of Table Mountain, important features of which were the sculpture work of J. M. Swan, R.A.—the bronze lions and a head of Rhodes himself—and the mounted equestrian figure—"Physical Energy"—by G. F. Watts, R.A.

The end of the South African War saw Baker in full practice in the Transvaal and South Africa. In addition to the Government buildings at Pretoria—the administrative capital of South Africa—he carried out the cathedrals at Cape Town, Pretoria, and Salisbury, and many colleges and schools. Amongst the houses he built in South Africa are the Government House in Pretoria, and that for Sir Lionel Phillips, afterwards the governor-general's Johannesburg home. He also designed the buildings for the S. A. Institute of Medical Research at Johannesburg, and laid out many model mining villages on the Rand. His works in England include Sir Philip Sassoon's house at Lympne and the restoration of Chilham Castle, Kent. He was appointed one of the three principal architects for the war cemeteries in England and Flanders, and carried out many war memorials in England, amongst them those at Canterbury, Winchester and at Harrow school. Baker was appointed in 1913 joint architect for the new Imperial City of Delhi, in collaboration with Sir Edwin Lutyens. For this great scheme he designed the buildings for the secretariats, the Legislative Assembly, the Councils of State and of Princes, and the Viceroy's Dome for General Assembly.

BAKER, NEWTON DIEHL (1871–), American politician, was born at Martinsburg, W. Va., Dec. 3 1871. He was educated at Johns Hopkins (A.B. 1892) and Washington and Lee (LL.B. 1894). In 1896 he became private secretary to Postmaster-General Wilson, but the following year opened a law office in his native town. Later he moved to Cleveland, O., where in 1902 he was made city solicitor and in 1912 mayor. The latter office he had held for two terms when in 1916 he was appointed U.S. Secretary of War by President Wilson. He had declined the Secretaryship of the Interior in 1912. After the outbreak of the World War he endorsed the Administration's peace policy, supported the League to Enforce Peace, and urged that the national guard be tried fully before compulsory service be decided upon. After America entered the war he recommended moderation towards conscientious objectors and forbade men in uniform to interfere with anti-conscription meetings. The charge of pacifism was often brought against him, and his career generally as Secretary was widely condemned throughout the United States as lacking in energy, foresight and ability, and especially for his failure to prepare adequately in the months immediately preceding the American declaration of war.

BAKST, LEON NICOLAIEVICH (1866–), Russian painter and theatrical designer, was born at St. Petersburg May 10 (April 27 O.S.) 1866. He was educated at St. Petersburg, where he afterwards studied art, and later went to Paris, subsequently returning and working in Moscow. In 1906 he settled in Paris, and soon became popular as a designer. In 1909 the Imperial Russian Ballet first visited Paris, and Bakst at once leapt into fame through his designs for the setting of the ballets *Schéhérazade* and *Cléopatre*, followed in 1912 by *L'Après-Midi d'un Faune*, *Hélène de Sparte*, and *St. Sébastien*, and in 1913 by *La Pisanella*. He published in 1913 an article in *La Nouvelle Revue*, entitled "Les Problèmes de l'Art Nouveau."

See *L'Art décoratif de Léon Bakst*, with appreciation by Arsène Alexandre, translated by H. Melvill (1913).

BALAKIREV, MILI ALEXEIVICH (1836–1910), Russian musical composer (*see* 3.234), died at St. Petersburg in May 1910.

BALDISSERA, ANTONIO (1838–1917), Italian general, was born at Padua 1838, and died at Florence, on Jan. 9 1917. His birthplace in 1858 being still under Austrian rule, young Baldissera entered the Austrian army, in which he served with distinction in an infantry regiment; he was captain in the 7th Jägers at Custozza (1866). But when Venetia became Italian, he opted for Italian nationality, retaining his rank in the Italian army. In 1879 he was promoted colonel of the 7th Bersaglieri and major-general in 1887, when he went to Eritrea under Gen. Asinari di San Marzano, remaining in the colony as governor after the latter's return. Both as a soldier and an administrator he showed high qualities. He occupied Asmara, Keren and other territories, defeated the armies of Ras Alula, and had planned still further extensions of Italian dominion, profiting by the anarchy of Abyssinia. He organized the admirable native troops (Ascari), developed agriculture and built roads. But owing to a disagreement with the home Government over his Abyssinian policy he asked for and obtained his recall after two years of successful activity. In 1892 he was promoted lieutenant-general. When war with Abyssinia broke out in 1895 the then governor of the colony, Gen. Baratieri, did not enjoy the confidence of the Government, which decided to send out Baldissera once more. Although the appointment was kept secret, Baratieri got wind of it, and this probably decided him to attack the enemy with an inferior force and insufficient supplies, hoping to win glory for himself before his successor's arrival. The result was the disaster of Adowa (March 1 1896); when Baldissera arrived he found a defeated and demoralized army, and the victorious enemy advancing in force. With lightning speed he reorganized the remains of Baratieri's army and the reënforcements just landed, freed the beleaguered garrisons of Cassala and Adigrat, drove back King Menelek's army and reoccupied a large part of the lost territory. But peace was concluded before he had completely retrieved the defeat of Adowa, and he was forced to limit his activities to the internal reorganization of Eritrea. But even this task he could not carry out as thoroughly as he wished owing to the opposition of the home Government, which was tired of African affairs. In 1897 Baldissera returned to Italy and resumed his duties in the home army, successively commanding the VII. and VIII. Army Corps. In 1906 he was made a senator. In 1908 he had to retire from the army under the age limit.

BALFOUR, ARTHUR JAMES (1848–), British statesman (*see* 3.250), was confronted, as Conservative leader, after the general election of Jan. 1910, with a situation of some embarrassment. He had to endeavour to save the effective authority of a second Chamber and to avert Irish Home Rule, with his supporters not yet completely united on the issue of Tariff Reform, and in face of a Liberal Ministry dominated once more by a body of 80 Irish Nationalists, who held the balance of power in the House of Commons, and who notified their intention not to vote for Mr. Lloyd George's disputed budget unless their forward policy was adopted. He advocated House of Lords reform as an alternative to the Ministerial Veto Resolutions, which he denounced as irrational; and when Mr. Asquith announced that, if he could not secure statutory effect for his policy in that Parliament, he would not dissolve except under conditions which would ensure that the will of the people should be carried into law in the next Parliament, he exclaimed that the Prime Minister had "bought the Irish vote for his Budget, but the price paid is the dignity of his office." In the lull in the party fight which followed the death of King Edward, Mr. Balfour welcomed the suggestion of a conference between the parties to endeavour to arrange a compromise, and was one of the eight leaders who met on 21 occasions between June and Nov. without coming to an agreement. When the

conference failed and ministers announced another dissolution, Mr. Balfour did his best to rouse the country to the dangers which, in his opinion, threatened it. In a speech at the Albert Hall he expressed his readiness to submit Tariff Reform to a referendum, and maintained that the Government for their part should be ready to submit Home Rule also to a referendum. The offer was not accepted. When the second general election of 1910 confirmed the verdict of the first, the dissatisfaction with Mr. Balfour's leadership, which had been long entertained by a considerable section of the Unionists, began to spread. It was pointed out that he had now led the party to three electoral defeats in succession; and this record was contrasted with Lord Salisbury's victories in 1886, 1895 and 1900. The course of the session of 1911 intensified this dissatisfaction. Mr. Balfour did indeed fight the Parliament bill, in its passage through the House of Commons, with courage, persistency, acuteness and passion. While he admitted the need for some change in the Constitution, and promoted Lord Lansdowne's measure for reconstructing the House of Lords and making it a Chamber partly hereditary, partly nominated, and partly elective, he denounced the Ministerial bill as practically constituting single-chamber government. Ministers, he said, were forcing constitutional changes on the country by coercion as they had imposed them on the country by fraud. In committee he strove hard, but in vain, to get fundamental laws exempted from the operation of the bill. But he shrank, as in 1832 the Duke of Wellington had shrunk, from encouraging the House of Lords to persist in opposition, when ministers announced that they had obtained the King's consent to the creation of sufficient peers to make its passage certain. He did indeed move a vote of censure imputing to ministers a gross abuse of the Constitution in the advice they had given to the Crown; but he declared that he would stand or fall with Lord Lansdowne in the recommendation which the latter made to the Unionist peers to abstain from further resistance as being no longer free agents. This attitude was passionately resented by a large number of "Diehards," who organized themselves under the leadership of Lord Halsbury, and with the approval of Mr. Joseph Chamberlain, then in retirement owing to illness. Mr. Balfour's counsel prevailed, and the bill was allowed to pass; but his position and authority as leader had been seriously shaken. Though both he and leading "Diehards," in speeches in the autumn, treated the dispute as ancient history, he decided that the time had come for him, after 20 years of leadership, to resign; and he announced his decision to a meeting of the Conservative Association in the City of London on Nov. 8. He said that he desired to abandon his heavy responsibility before he could be suspected of suffering from a sort of petrifaction in old courses and inability to deal with new problems: and that he felt he had not the vigour, at his time of life, again to conduct a ministry. He treated the unrest in the party as nothing exceptional, and spoke of Unionism as on the upward grade. The announcement, in spite of the signs of discontent, came as a great shock to the party and the country; and the Prime Minister, Mr. Asquith, himself expressed the general feeling when he said at the Guildhall banquet next day that the resignation involved an irreparable loss to the daily life of Parliament.

Mr. Balfour was then only 63, and his powers as a parliamentarian were really at their height. Although after his resignation of the Unionist leadership he devoted more time to his manifold other interests in life—philosophy, science, literature, music—he still took at intervals a prominent part in debate, and made occasional speeches in the country, giving throughout a loyal support to his successor in the House of Commons, Mr. Bonar Law. The renewed controversy on Home Rule afforded him a great opportunity, and the powerful series of speeches which he delivered, at Westminster and elsewhere, in the course of the next three years, did much to awaken Great Britain to the imminent danger of civil war in Ireland, and to force ministers into the policy of excluding Ulster, in some form or other, from the operation of their bill.

When the World War broke out he cordially accepted the policy of the Unionist leaders in sinking all political differences in support of the national Government. Speaking at the Guildhall on Lord Mayor's Day 1914, he said that the Allies were fighting for civilization and the cause of small states, and, whether the war was short or long, they would triumph. In this spirit he joined the first Coalition Government in May 1915, accepting the first lordship of the Admiralty under Mr. Asquith; and from this time onward he took a statesman's share in the conduct of the war, and in the making of peace. The Admiralty had been distracted by a quarrel between Mr. Churchill, the First Lord, and Lord Fisher, the distinguished admiral, who was First Sea Lord. Both had now resigned, and Mr. Balfour appointed an eminent scientific sailor, Adml. Sir Henry Jackson, as First Sea Lord, and speedily restored the harmony of the Board. He also reversed Mr. Churchill's policy of differentiating against prisoners from submarines as compared with other German prisoners, though he insisted that there was no change of opinion as to the unlawful, mean, cowardly, and brutal character of their acts. In introducing the Navy Estimates in 1916 he said that, except in armoured cruisers, the fleet was far stronger than when war broke out; that ships, guns and ammunition had increased and would increase; and that the *personnel* had more than doubled. His principal critic was Mr. Churchill, who averred that the existing Board had not so much energy, speed, push and drive as his own, and who, to the astonishment of the House, recommended the recall of Lord Fisher—a suggestion upon which Mr. Balfour commented severely. Perhaps the best work which he did at the Admiralty was the issue, at intervals, of some cogent papers, mainly for the benefit of the Americans, vindicating the great work of the British navy in the war, and exposing the fallacies involved in the captivating phrase, "the freedom of the seas." The chief naval battle of the conflict, the battle of Jutland, was fought during his term of office; and he incurred widespread criticism by the manner in which the news was officially communicated to the public, the great losses in men and ships being dwelt on to such an extent as to suggest that, instead of being a victory, the action was a defeat. In a speech a few days later he claimed that, as a result of the fight, the Germans were relatively far inferior to what they had been. In late Oct. there was a daring German raid by 10 destroyers into the English Channel; an empty British transport and one British destroyer were sunk and another destroyer seriously damaged. Mr. Balfour confidently predicted at the Guildhall on Lord Mayor's Day that any further Channel raiders would suffer disaster. His confidence was probably based in part on a new arrangement of the high naval appointments, which he announced before the end of November. Sir John Jellicoe was brought into the Admiralty as First Sea Lord, and Sir David Beatty was appointed to succeed him as commander-in-chief. These changes were promptly followed by a change of First Lords when Mr. Lloyd George formed his Ministry in Dec. 1016. Lord Grey of Fallodon declined to continue at the Foreign Office under the new Prime Minister; and as it was essential to have a man of experience and weight there, the post was pressed upon Mr. Balfour, who had in times past occasionally acted as Foreign Secretary in Lord Salisbury's absence, and had been intimately associated, during his Premiership, with Lord Lansdowne's work in the department.

Mr. Balfour took up his new duties as Foreign Secretary only a few weeks before Germany instituted the unrestricted submarine warfare which brought the United States into the war; and in April 1917 he headed a British mission which visited America in order to arrange for regular coöperation between the two countries. His attractive personality greatly impressed his hosts, and he received the compliment of being invited to address the House of Representatives on May 5; his speech showed a complete sympathy, that was highly appreciated, with the spirit in which the United States had entered the war. He subsequently proceeded to Canada, and there addressed the two Houses of Parliament. The concentration of power in the

hands of the War Cabinet, and the great personal ascendancy which Mr. Lloyd George, as Prime Minister, rapidly acquired, both tended rather to reduce the importance of the Foreign Secretary during Mr. Balfour's tenure of the post. It should be noted, however, that it was Mr. Balfour, as Foreign Secretary, who in Nov. 1917 gave a promise on behalf of his Government to provide a "national home" for the Jews in Palestine after the war. The exceptional amount of work to be dealt with at this period impelled him to ask for extra help in the office; and Lord Robert Cecil was taken from the Ministry of Blockade in the summer of 1918 and made an assistant Secretary of State. Mr. Balfour went to the Paris Conference in 1919 as the second British plenipotentiary; but as eventually the terms of peace were settled by a council of three, Mr. Wilson, M. Clemenceau, and Mr. Lloyd George (or of four, when the Italian prime minister attended), his share in the work was somewhat subordinate, though he appended his signature to the Treaty of Versailles, and to the treaty of guarantee to France against German aggression. When the Conference was over, he was glad to be relieved of the burden of a laborious office, and therefore relinquished the Secretary of State's seals to Lord Curzon, but remained himself in Mr. Lloyd George's Cabinet in the honourable but comparatively sinecure office of Lord President of the Council. He was appointed chief representative of the British Government at the first Assembly of the League of Nations in 1920; and also at the Disarmament Conference at Washington, D.C., in Nov. 1921.

Mr. Balfour's eminence, and his patriotic readiness to resume in war-time, in spite of advancing years, official labours in a secondary position, were suitably recognized on the King's birthday in 1916 by the grant of the Order of Merit. In 1919 he received a distinction which he must have peculiarly valued, when he was elected chancellor of his old university, Cambridge, in succession to his brother-in-law, Lord Rayleigh.

(G. E. B.)

BALFOUR OF BURLEIGH, ALEXANDER HUGH BRUCE, 10TH (or 6TH) BARON (1849–1921), British politician, was born at Kennet, Alloa, Jan. 13 1849, the son of Robert Bruce of Kennet. He was educated at Loretto, Eton and Oriel College, Oxford, and in 1869 was restored by Act of Parliament to the barony of Balfour of Burleigh, to which he was entitled by his descent from the 5th baron, who was attainted after the Jacobite rebellion of 1715. He first came into public notice as a member of the factory commission of 1874, and afterwards acted as chairman of many other commissions, including that on educational endowments (1882–9). From 1889 to 1892 he was parliamentary secretary to the Board of Trade in the Conservative Government, and from 1895 to 1903 (when he resigned as a Free Trader opposed to tariff reform) Secretary for Scotland. In 1903 he became chairman of the commission on food supply in time of war, and in 1909 of that on trade relations with Canada and the West Indies, receiving in 1911 the G.C.M.G. as a reward for his services. From 1916 to 1917 he was chairman of the committee on commercial and industrial policy after the war. Lord Balfour, who received hon. degrees from all the Scottish universities, was from 1896 to 1899 lord rector of Edinburgh University and from 1900 chancellor of St. Andrews University. In 1904 he was appointed Lord Warden of the Stannaries. He published in 1911 *The Rise and Development of Presbyterianism in Scotland.* He died in London July 6 1921.

BALKAN CAMPAIGNS (1914–8): *see* SALONIKA CAMPAIGN and SERBIAN CAMPAIGNS.

BALKAN PENINSULA (*see* 3.258).—Geographically speaking, the Balkan Peninsula is a meeting-point of European and Asiatic relief (*see* fig. 1). The Dinaric ranges belong to the Alps, the Carpathians and the Balkans seem to be connected in an arc, and the main tectonic systems of the peninsula have a geological structure similar to the ranges of Asia Minor from which they have been separated since the Pliocene or diluvial period. In the same way, areas of strongly contrasted climate are to be found in close proximity, *e.g.* Mediterranean on the Adriatic and Aegean coast; Steppe, like that in Asia, on the extensive plain formed by the Danube and the Maritsa; Central European in most of the peninsula; Alpine on the higher summits (*see* figs. 1 and 2). They are sometimes intermingled: valleys which reach far into the mountain masses enjoy a Mediterranean climate as, *e.g.* the lower Drin valley in Albania.

The distribution of soil affects the character of the vegetation as much as climate: north of the Balkans and of the Kopaonik plateau extensive tracts are covered by lake or marine deposits, loess and humus, where steppe meadows, forests and general cultivation prevail. On the central highlands are coniferous forests and Alpine pastures, while the isolated basins show the characteristics of northern soils and vegetation. The slopes facing the Aegean Sea, like those facing the Adriatic, give rise to deciduous bush and *pseudo-mâquis*. The extreme limit of Mediterranean vegetation sometimes reaches as far as the upper Morava and the depressions S. of the Balkans in the eastern part of the peninsula, but does not extend farther than a few miles from the Adriatic or a few hundred metres above sea-level in the western part. To N. and E. of this limit, large areas, especially in Bosnia and Serbia, are still covered with forests of oak and birch trees, remnants of extensive primitive forest growth in the valleys as well as on the hills; while to S. and W. low scrub prevails on the bare rocks. Tobacco, rice and cereals are grown in the fertile plains of Thrace and Macedonia, olive and orange trees flourish in the most sheltered places along the coast.

The extension of mountain barriers, climatic influences and zones of vegetation do not alone make the Balkan Peninsula a world by itself. Peripheral influences travel from Italy over the Adriatic, by the straits and the island-dotted Aegean to the indented Hellenic coast, then through the great longitudinal depressions which traverse the peninsula from N.W. to S.E. The morphological features combine to constitute the basis of natural regions—the Aegean, the Balkans, the Morava-Vardar and the Pindo-Dinaric regions—whose main characteristics depend more on morphology than on ethnography or history.

Natural Regions.—The Aegean region is remarkable for the indentation of its coast. On the Hellenic part (Peloponnesus and Euboea) each morphological feature—islands, gulfs and headlands—points S.E. towards Asia Minor and turns its back to Europe. Karstic characteristics are well developed in the limestone areas of the Ionian coast. The climate is typically Mediterranean: summers are rainless, the atmosphere is clear and temperature is high. The rivers are not perennial. Among the *mâquis* growth, cultivation is restricted to small fields like oases. On the slopes and in the bottoms of the sheltered depressions, oranges, grapes, lemons and pomegranates survive the dry summer: the olive is prominent in the landscape. Animal as well as vegetable life is very restricted. The isolation of the units and the poorness of the soil would have almost prevented development if the population had not turned seaward, attracted by extraordinary opportunities for fishing, navigation and trade. The Aegean is the only region in the peninsula inhabited almost exclusively by Greeks, mostly seamen or traders, living in towns of the Mediterranean type, with high stone houses and narrow streets, or in large villages on terraces.

The Thraco-Macedonian region combines the characteristics of the Hellenic and continental regions. The coast is also indented, but the large valleys of perennial streams (Vardar, Struma) give access to the gulfs. The land surface, chiefly consisting of crystalline, metamorphic rocks, denuded, displaced and dislocated, shows sharp contrasts of plateaus and basins, and here and there residual ridges. The tectonic basins, when not filled by the sea, as at Salonika and Orfano, are occupied by alluvial and tertiary lake deposits as in Thessaly and Thrace, or by lakes (Doiran, Langadha, Beshik) or, in the valleys, by marshes. The climate is half continental and half Mediterranean with rainy summers and cold winters. The *Vardaras* blowing in the rear of the deep winter cyclones brings snow to the hills and freezes the coast, while violent south-west winds bring excessive heat in summer. The proximity to the coast of high hill masses has a great influence on the vegetation: the true *mâquis* growth extends to an altitude of 200 metres on the coastal slopes, but olive and vine cultivation reaches as high as 400 metres. Oaks and chestnuts, at first scattered, increase with the elevation until they form forests, then coniferous trees appear and finally the cloud-wrapt Alpine summer pastures provide an area of "transhumance" to Kutzo-Vlakh and Slav shepherds, who spend the winters on the coastal plains. The area available for agriculture lies in the basins—Thessaly for wheat, Seres for cotton, the plain of Salonika for rice, Kavalla for tobacco. The towns (Salonika, Kavalla), inhabited by Spanish Jews, Turks and Greeks, are built like amphitheatres on the slopes and the villages are inhabited by Slavs and Arumans. The latter are often of the Turkish *Chiftlik* type with square rooms grouped around the landowner's house, or are composed of houses made of sun-dried bricks.

Strongly contrasting with the Aegean, the Balkan region is a continental mass. The straight Black Sea coast does not favour peripheral influences travelling inward, and the high Rila and Rhodope systems form a barrier against western penetration. The west-east folded Balkans divide the region into two parts, the lower Danubian plateau on the N., and the Maritsa basin on the S., but

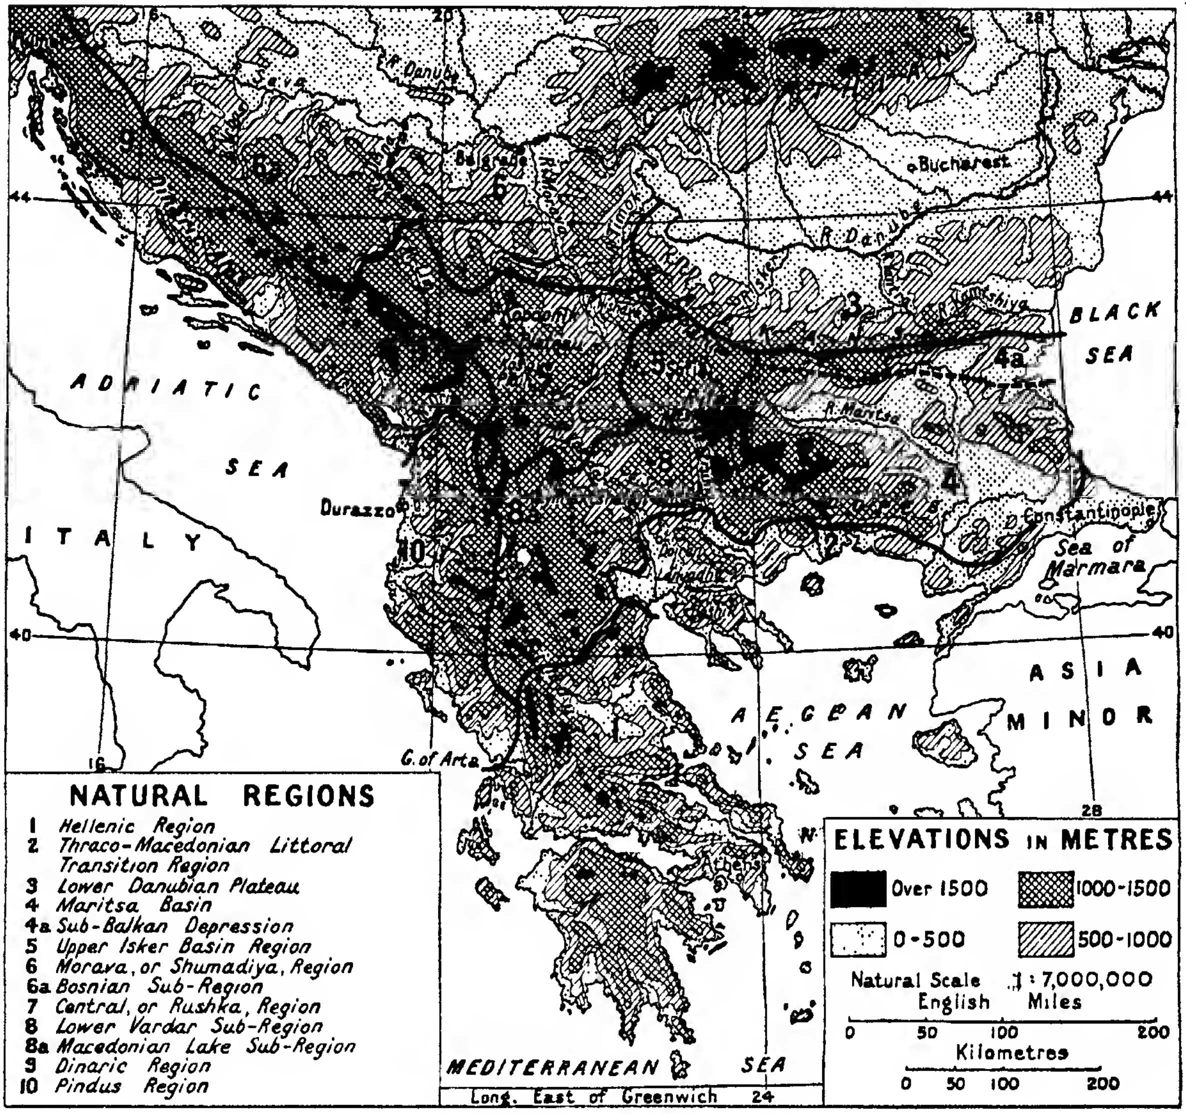

FIG. 1.

low passes render communication easier. The lower Danubian plateau is the only part of this region in which relief, climate and production are almost uniform; the unbroken monotonous surface is dissected regularly by deep-cut asymmetric valleys facing fault scarps, running from S. by W. to N. by E. Like southern Russia and Rumania, it is covered with neogene sediments and loess of wonderful fertility, but trees and grass are very scarce out of the valleys, the water table being too deep down. During excessively dry summers the small streams cease to flow, and in cold winters even the Danube is frozen. Summer droughts make the crops of wheat uncertain. The characteristics of extreme continental climate and vegetation increase eastward in Dobrudja and favoured the settlement of the steppe Slavs and Ugro-Finnish Bulgars, while the uniformity of relief and the proximity of Constantinople made control of the country by the Turks easy.

The central and western Balkans stand out in contrast: high hill masses of palaeozoic schists, granite and mesozoic rocks, often chalk, are bounded on the south by abrupt fault scarps of a few hundred metres overlooking the plains, and, on the north, gradually fall in folded ranges. The eastern Balkans, consisting of sandstone, schists, flysch, are lower. Unlike the mountains of the central parts of the peninsula, the folded Balkans contain few faulted basins (Orhaniye). Except for the Yantra and Isker running south-north through the *massifs* and the Kamtshiya and Provadiya running west-east through epigenetic ravines, they have an undiversified drainage and are like the basins cultivated with oats, barley and potatoes, while cattle are raised on the grassy and forested hills. Between the schists and granites of the Rhodopes and the mesozoic rocks of the Balkans lies the tectonic basin of the Maritsa, showing strata of sandstone and paleogene limestone below alluvial deposits. The climate varies: it is Mediterranean as far north as Philippopolis, favouring the cultivation of maize, tobacco, the pepper plant, the vine and mulberry trees along the Maritsa; in the east around Jamboli and Stara Zagora a steppe climate prevails, favouring wheat. The small tectonic basins of the sub-Balkan depression are liable to lesser extremes of climate and are well known for their rose gardens as at Kazanlik and fruit orchards as at Zlatitsa. The whole region facing Constantinople felt Byzantine or Asiatic influences strongly and was the first domain of the Bogomils during the Middle Ages.

West of Sofia, the upper Isker basin is a natural Viskar unit. In the centre, the Viskar and Lulyin mountains are an area of eruptive rocks and mesozoic strata folded east-west and surrounded by low limestone ridges, gentle on the north (Srbnitsa) and ragged on the south (Vlashka). Isolated tectonic basins and karstic depressions, such as Kyustendil and Grahovo, are the only cultivable areas. The country, poor and deforested, is a barrier to communication—the Shŏp tribe lives there under primitive conditions with Bulgars settled at the approaches. Sofia overlooks the Isker, Struma and Nishava, leading respectively to the Danube, to the Aegean and to the Morava-Vardar. To the south, the Rhodope system, a high mass showing glacial valleys and cirques, and almost perennial snows, is covered with forests or meadows partly inhabited by Pomaks, Yuruks and by transhumant Kutzo-Vlachs (*see* fig. 3).

Unlike the Balkan the Morava-Vardar region is not open to eastern influences. Its main communications are longitudinal, along a depression leading from Central Europe to the Aegean Sea. Various formations are displayed in the relief—the pretertiary Rhodope mass, the tertiary Dinaric and Carpathic ranges, the eruptive rocks of the Ibar and Bregalnitsa with their rich iron and copper fields, most of them by their great height impeding the west-east

communications. The *massifs* enclose tectonic basins still or formerly occupied by lakes, and connected with the Morava and Vardar valleys or with the Ovtshe Polye and the Strumitsa. North of Nish, the Shumadya is the southern part of the neogene Pannonic lake. It slopes gradually by seven terraces from 960 metres to 120 metres towards the Danube and the Sava. On a lacustrine soil, the monotony of the crops is broken only by forested hills—former islands in the Pannonic lake and remnants of an ancient extensive forest. Similar morphological features are found E. of the Carpathic Rtany (1,566 metres) in the Timok basin, previously occupied by a Pliocene lake. The climate is of modified Central European type, with abundant rain; and a long mild autumn, and a soil of loess and humus make Shumadya the best maize district in the peninsula.

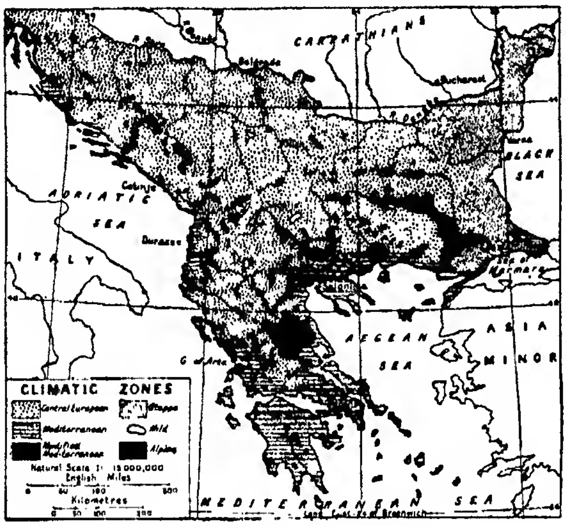

FIG. 2.

Pigs are raised in the decreasing forest area. White villages, crowded by a purely rural population reputed for good sense, humour, democratic spirit and strong national traditions, are scattered among green plum orchards. In close touch with Central European civilization, Shumadya early cast off the yoke of distant Constantinople and became the Piedmont of the Serbian renascence. South of Nish the country is more isolated: Rashka is composed of tectonic basins (Nish, Kosovo, and Skoplye) encompassed by abrupt slopes of compact masses of schists and limestone. The higher summits show ancient glacial features. Towards the south, the relief is more and more complex. In Macedonia, crystalline schists and granites of the Rhodope system prevail on the east, sandstones, serpentines and limestones of the Pindus on the west. Among the latter are higher summits (Perister, Kajmakcalan, 2,525 metres) and tectonic basins (Presba, 900 metres). The climate is continental except in the south-east where several Aegean gulfs penetrate the interior along the Struma and Vardar, but winters last longer and are colder than in Shumadya. The lake-floored basins are occupied by orchards or wheat and flax, but forests and summer pastures of the hills are a region of "transhumance," especially in the west, equidistant from the Adriatic and the Aegean. Fields of poppies and rice and vineyards occupy large spaces in south-eastern Macedonia. The inhabitants live mostly in the basins but also on the terraces. In Rashka and Macedonia towns are more of the Turkish type—with their aggregations of wooden shops on narrow, dirty streets grouped round a central covered bazaar. In Shumadya, more open to European influence, the town streets converge towards a central *piazza* or market, and the villages extend along valleys and roads, contrasting with those of the *Chiftlik* type of the Vardar country. There isolation of small natural units helped the particularism and submission to Turks which are still noticeable amongst the people, though disappearing through the influence of returned emigrants.

The Pindo-Dinaric region differs from that of the Morava-Vardar in its lack of penetration and union and by a well-defined morphology. From the Lyublyana basin to the Gulf of Arta, it is delimited on the E. by depressions, among which are the upper valleys of the Vrbas, Neretva and Drin. The beds are folded and dislocated N.W.-S.E., so that from W. to E. the littoral area (*primorye*) is succeeded by a barren karstic plateau (*zagora*) and then by high mountain ranges (*planina*) parallel to the coast, which is a coast of submergence of which the higher parts form islands. The strike of the folds restricts transverse relations, except S. of Scutari where, in the Pindus ranges, it becomes west-east. Crests of the underlying carboniferous rocks often appear through the folded and dislocated surface, but the ragged dolomitic peaks are higher. Depressions and gentle slopes prevail in the Bosnian schists of the east, steps of cretaceous limestones sloping from 2,000 metres to 800 metres in the plateau of the west. These steps have been transformed into barren karst, with subterranean rivers, high temperatures and abundant rains, as far as a new line of ranges along the coast. Important mineral deposits, especially iron and copper, are found in the palaeozoic and tertiary rocks.

The karstic morphology is less important where the schists, sandstones and serpentine predominate in the Pindus regions. Instead of being indented and island-dotted, as in Dalmatia, the Albanian coast is straight and deltaic. The Mediterranean type of climate extends farther than in the Dinaric regions. Winters last long and snowfalls are abundant on the *planinas*, autumn is early in the *zagora*, and the barometric gradient in the "bora," a wind blowing from the mountains towards the Adriatic cyclones, is extremely steep. The rainfall reaches 4,640 mm. at Tserkvitse in the Gulf of Cattaro. The vegetation is varied: the slopes of the *planinas* up to 1,700 metres are occupied by forests, farther up by Alpine villages and fields of summer crops, then by pastures. Intensive agriculture is possible only on the "terra rossa" of the depressions in the karst. Mediterranean cultivation prevails on the coast. The alluvial Pindus valleys are cultivable areas and the Albanian slopes are covered with pasture and olives up to Elbassan on the east. The population is scattered except on the edge of the *polye*, where it concentrates in order to avoid building on the limited "terra rossa" area. The Alpine type of house prevails on the *planinas* from Carniola to the districts occupied by the Vasoyevitschi tribe in the upper Lim valley, the *Chiftlik* in southern Albania, the Mediterranean on the Primarye and some parts of Zagora. The towns in Albania are of mixed Turkish and Mediterranean type (Durazzo, Valona). On the other hand, Spalato, Zara and Ragusa, old harbours along small bays and narrow headlands, are an element of maritime life which helped Slav and Latin influences to combine in the early cities, producing a high civilization. On the *planinas* a pastoral life favoured a sturdy independence. The same characteristics are noticeable in the Pindus region which, isolated from the sea by marshes and lagoons, is still the most extensive domain of tribal life. Thus, unity of life, as well as morphologic features, is a determinant factor of the natural region.

Area and Population.—The political divisions do not exactly correspond with natural units described above:—

Political Division (1921)	Area in sq. km. (1921)	Pop. (1910 census)	Pop. per sq. km.
Yugoslavia (S. of the Danube and Sava)	202,051	8,842,667	43
Dobrudja (Rumania) . . .	23,304	360,000	15
Bulgaria	102,740	4,700,000	38
Turkey	10,000	1,400,000	14
W. Thrace	12,000	300,000	25
Greece	142,000	5,850,000	37
Albania	26,000	780,000	30
State of Fiume	21	49,806	2,371
Balkanic Italy (country of Gorizia E. of the Isonzo, W. Carniola, Istria, Trieste and Zara)	7,969	739,952	92
Totals . .	526,085	23,022,425	42

Civilizations and Metanastasic Movements (*see* fig. 3).—Various civilizations—Byzantine, Turkish, Occidental and Patriarchal—were adapted in their distributions to geographical conditions, each of them leaving a deeper impress in a definite area. Byzantine influence impressed material life and moral ideals throughout the Middle Ages, and it was carried by the Greeks and Aramuni along the longitudinal depressions under Turkish rule up to the Danube and the Sava, but could not be maintained in the areas successively cleared by the Turks. It does not now appear farther north than the Balkans and the Shar Planina. It is still noticeable in the city life, relying on strict trade unions, in dogmatic quarrels, and in the struggle to make money at all costs. Turkish and Oriental influences first came across the straits and the island-dotted Aegean. The Greeks and Turks brought wheat, fruit trees, flowers, and methods of irrigation from Asia Minor, the last of these especially into Bulgaria. The Islamized Serbs extended the area of Turkish habits and mentality far north and west into Bosnia. Turkish and Oriental influences are still manifested in special care for weapons and harness, in lazy habits, and in a strange mixture of goodness with brutal passions. Under submission for so long, the Christians still maintain the *raya* mind and conceal their feelings. In Turkish territory and Thessaly the economic system of tenure called

Chiftlik persists. The *begs* and *agas*, and Greek landowners of Thessaly, the former being descendants of the landowners who adopted the creed of the conquering race, own the ground cultivated by the *kmets* or *chiftshiye* and impose heavy taxes upon them.

The western European countries and the Balkan world came early into contact. The Romans crossed the Adriatic and Latinized the old Illyrian tribes up to a line from Alessio on the Adriatic to Ratiaria on the Danube, south-east of which the Greek language prevailed. Later, the House of Anjou in Albania, the Franks in Constantinople, and the maritime and commercial empires of Genoa and Venice hardly carried Occidental in-

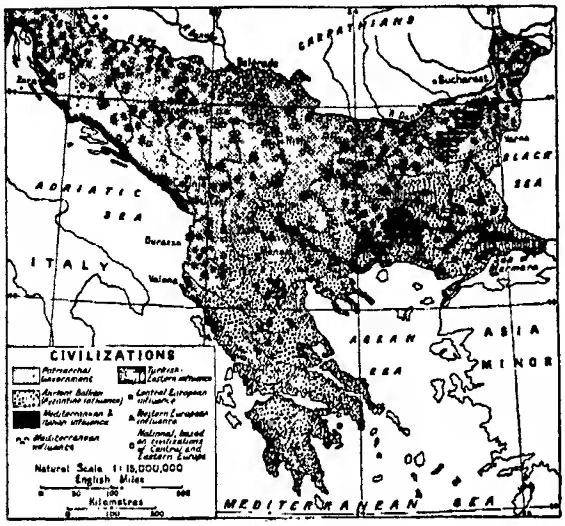

FIG. 3.

fluences over the main ranges into the interior of the peninsula. But the Mediterranean type is conspicuous in Dalmatia and in Constantinople, and the Latin is less noticeable on the *planinas*. Occidental architecture may be noticed in a Serbian church of the 13th and 15th century at Detchain. From that time, in consequence of these commercial and intellectual relations, a few words of Latin origin were introduced into the Serbo-Croatian language. After the 18th century it was a principle of Austrian policy to carry Central European influences far southwards; the Austrians brought their habits of city life, their methods of trade, their engineering, and their house furniture, but did not make their mark on intellectual development. North of the Shar Planina and of the Balkans, except on the coast and in the Serbian plains, the patriarchal type of civilization prevails. It is also noticeable in Albania. Its main characteristics are the organization of the tribes in Montenegro, northern Albania and Rashka, and that of the *Zadruga* from the Adriatic to the river Iskar. In the latter three or four families live together, obeying the oldest member of the group, and cultivating ground which is owned in common. The *Zadruga* is chargeable for the taxes, controls the expenditure, is responsible by law for, and makes profit on the work of, each member. Some groups consist of as many as 70 members. The ground, except forests or pastures (*stojer*), becomes more and more divided up. The nucleus of the tribes is made up of old families related together and enlarged by the admission of foreign groups, or by conquest of new territories. The Montenegrin tribes hardly made a livelihood on the barren karst and had to keep small in number; while the Rascian tribes, in an area full of resources, became more and more important. On account of geographical isolation and the prevention of exogamy amongst the old tribes, tribal life developed into particularism, but the wars against the Turks united those tribes which, when not fighting, were occupied only in pastoral pursuits or the leading of convoys.

The distribution of civilization has been greatly influenced by metanastasic movements. The invasion of the Turks in the 14th century determined local migrations, especially among the Serbs. The Dinaric Serbs from Montenegro and Herzegovina moved eastward and settled in the forest glades of Shumadya, or northwards along the Dinaric ranges as far as Istria and Carniola. People from Kosovo and Prizren moved northwards and settled in the plains and valleys of eastern Shumadya. The Macedonians moved along the Vardar and Morava valleys and, with the Serbians of the old districts, crossed the Sava and Danube and settled in Styria, southern Carniola and Croatia. Among the Bulgarians, the *Balkanyi* alone left their mountains for the lower Danubian or the fertile Thracian plains. The Albanians often changed place. Pushed back from the Black Drin by the Slavs in the 6th and 7th centuries, most of them adopted the creed of the Turks in the Middle Ages, and travelled freely through the whole peninsula; the half-Serbian, half-Albanian Malissores settled at Novibazar; a few Mirdites pushed up to Kosovo; the central Albanians to near Skoplye and Tetovo; the southern Albanians to the Peloponnesus. Along the main roads are Greek commercial colonies and Turkish military posts. The gradual clearing of the peninsula caused metanastasic movements of the Turks back towards Constantinople and Asia, and of the Christians back to the homes of their ancestors. The Turkish domination was responsible for many migrations: after revolts, and every fourth year as one-fifth of the young Christians entered the Sultan's service as *Yenitsheri*, entire families took refuge in the high *massifs*. During the wars between the Turks and the Austrians in the 18th century, the Serbian insurgents, to avoid reprisals, had to follow the retreating Austrians. During the liberation wars led by the Kara Georgevitch in 1804 and by Milosh Obrenovitch in 1815 many Serbians migrated from Novibazar and Nish into Shumadya. Economic conditions also played their part in those movements: entire families left overcrowded cultivated areas for rich but less inhabited areas. Scarcity of food pushed 10,000 Montenegrins eastward into Serbia in 1890. Many *kmets*, trying to escape bad conditions of tenure, obtained land in the newly liberated territories. Those metanastasic movements brought about the redistribution of ethnic and religious groups, and extended the Orthodox Church into the domain of the Roman Catholic, north of the Sava and Danube. In the same way, the Dinaric dialect pushed back the Croatian, and the Kosovo dialect was spoken farther and farther northward. Everywhere the immigrants adapted themselves to the life of the inhabitants among whom they had to live, but also brought new customs and a new mentality.

Races.—Owing to the continual movement of the population, the ethnological boundaries do not coincide with those of the great natural regions. The Greeks came from Asia Minor in early historic times and settled in the coastal area, including the islands between Varna and Corfu. They assimilated the Romans in Byzantine times, the Slavs in and after the Middle Ages, the Aramuni from the 12th to the 15th century, and the Albanians after the 14th century. But even now their range does not extend far from the sea, its northern boundaries being the southern border of Albania, the river Bistritsa and Lake Beshik. Farther east, mixed up with Turks and Bulgars, and with many Greeks in such commercial centres as Constantinople, Adrianople and Salonika, they occupy Thrace equally with the Turks. In the peninsula and adjacent islands they probably number 4,500,000.

Declining since the 17th century, the Turkish population has disappeared from the northern towns and from the Rhodope and Balkan mountains, where names given by Yuruk shepherds are, however, still retained. The Turkish element is nowhere found in compact masses except in the east Balkanic regions, where the dry climate is similar to that of Asia Minor. Elsewhere, it exists only in isolated districts—in eastern Bulgaria, in Thrace, on the left bank of the Vardar and in the Bujak Kajlar basin. The total Turkish population of the peninsula scarcely exceeds 1,800,000.

The Albanians or *Shkŭpetar*, representatives of the primitive Illyrian tribes, were not Slavized like the Dalmats or Liburns. They live in the mountainous Pindus and Prokletye, encompassed by Yugoslavia and Greece, while, among them, the Slavs

Fig. 4

often occupy the valleys and littoral plains. They have lost ground in the north-east since 1878 and the withdrawal of the Sultan's authority.

The Aramuni, numbering approximately 160,000, are found in 154 detached settlements of the southern peninsula. They are nomad shepherds migrating between the mountains and the littoral plains. Remnants of the primitive Latinized population, they have continued to decrease since the 18th century, when it is estimated they numbered 500,000. Some of them have settled in the mountains after having made money as shopkeepers in large towns.

The Yugoslavs, numbering about 15,000,000 south of the Danube and Sava, are the most numerous people in the peninsula. They are divided into Serbo-Croat-Slovenes (10,000,000) and Bulgars (4,700,000), all agriculturists. The majority of the Serbs, Croats and Slovenes came from trans-Carpathian countries in the 7th century. The distinction between them does not arise from any linguistic, racial or even religious difference. The national spirit of the Serbs gained force after the battle of Kosovo in 1389. At the end of the 15th century, the Orthodox religion, diffused through the Serbians after metanastasic movements, became national, and it helps to maintain unity. The Serbo-Croat-Slovene Kingdom, generally called Yugoslavia, does not include all the Serbians, Croats and Slovenes of the Balkan Peninsula—more than 400,000 were annexed to Italy by the Treaty of Rapallo. The Macedonian Slavs extend southward to Hellenic territory, almost to the river Bistritsa.

The Bulgars, who descend from a fusion of the Slavonic element with a later Ugro-Finnish immigration, inhabit the kingdom of Bulgaria, parts of Dobrudja and Thrace. On account of the proximity of Constantinople and of the general geographical conditions, they were more submissive to the Turks than any other part of the population, so that the word "Bulgar" often meant a social state different from that of the Turkish conquerors. Its political meaning dates from the creation of the Exarchat in 1870 and the wars of liberation.

The remainder of the population is composed of Armenians, who live in trade centres like Constantinople; of Jews, immigrants from Spain who form half of the inhabitants at Salonika; and of gipsies, wandering, or in scattered settlements near large towns.

Religions.—The Turkish conquest was followed by numerous conversions to Islam, so that the Mahommedan population (3,000,000) exceeds the Turkish element. More than half of the Albanians and 32% of the inhabitants of Bosnia and Herzegovina have adopted the creed of the conquering race. The great bulk of the Christian population belongs to the Orthodox Church, of which the oecumenical patriarch at Constantinople is the nominal head. The Serbian, Bulgarian and Greek Churches are in reality autocephalous. Most of the Serbians, Croats and Slovenes of Slovenia, Croatia and Dalmatia, some of the Gegh tribes in Albania, and 22% of the population in Bosnia and Herzegovina belong to the Roman Catholic Church. Some Bulgars belong to the Uniate Church, which keeps Orthodox rite and discipline under Roman authority. The Gregorian and Uniate Armenian Churches each have a patriarch.

Languages.—The Slavonic and Greek Nationalists succeeded in preserving their language. Early in the 17th century, the Serbo-Croats in Ragusa had a common literature, written in Herzegovinian dialect. In the 19th century, under the influence of Vuk Karadjitsh, that dialect prevailed as the literary language. In Bulgaria, the actual language is that of Sredna Gora, for centuries written only in a few monasteries. The conventional literary language of the Greeks is a compromise. Albanian, a remnant of the ancient Thraco-Illyrian speech, belongs to the Indo-European family, but lacks literary distinction.

BALKAN WARS (1912–3).—This article gives an account of the wars of Bulgaria, Serbia, Greece and Montenegro as allies against Turkey in 1912 and 1913, and the short war which followed between the former allies, with Turkey and Rumania intervening, in the summer of 1913.

I. The Balkan League.—The formation of a military alliance between Bulgaria and Serbia, Greece and Montenegro in 1912 was the final step in an evolution which began in 1909, and in its last stages was hastened by the Italo-Turkish War of 1911. The immediate cause of war was the state of Macedonia under Turkish rule. On June 19 1912 a military agreement was made between the general staffs of Serbia and Bulgaria, in accordance with the previous political treaty of alliance signed on Feb. 29 1912. Greece followed suit with a political treaty in May and a military agreement on Sept. 22. Montenegro did the same in the course of the summer, and, while Turkey was still negotiating her peace with Italy at Ouchy, the four allies mobilized their armies (Sept. 30 and Oct. 1 N.S.). Turkey, since the Young Turk Revolution internally dislocated, was in no condition to meet their onslaught. Although the prestige of the individual Turkish soldier as a fighting man stood high, and the beginnings of many reforms in the education of staff and regimental officers had been made in the last few years, the military capacity of the army as a whole proved to be far below the reputation which it enjoyed amongst the military experts of Europe. Turkey's opponents, on the contrary, had in recent years not only rearmed themselves and secured their financial and political position, but also made those minute and careful preparations of detail which when the time comes translate themselves into smooth concentration, and regular, consistent operations.

Strategically no less than politically, Turkey was on the defensive. Her European possessions formed two separate theatres of war, Macedonia and Thrace, which were linked only by the coastal railway Dede Aghach-Seres-Salonika, and this line, open in its middle section to Bulgarian raids from the mountains on the N. and to Greek raids from the sea,[1] was of no high technical efficiency in any case. The dispersion of a large part of her army and notably of her reserves in Asia Minor, where rail communications were few, and roads ill-developed, made any reënforcement of the European theatres a matter of time and difficulty; in the case of Macedonia, such reënforcement was practically impossible save by sea. After a new survey of the situation in 1909–10 by Marshal von der Goltz it was decided to treat Macedonia as a self-contained theatre of war garrisoned at all times by a large army with Shtip (Štip) as its area of war concentration, and to constitute in Thrace a covering army which would be reënforced by the troops from Asia as they successively arrived, up to the strength adequate for offensive operations against Bulgaria. To assist the defense in the first, or waiting, period Adrianople was organized as a modern fortress, and Kirk Kilisse, an upland town on the edge of the Istranja Dagh, re-equipped with barrier-forts. The line of communication with Asia was secured against the Greek fleet by the Dardanelles fortifications, which enabled Rodosto to be used as an advanced base.

The peace-time distribution of the Turkish forces in Europe (other than garrison troops) was as follows: In Thrace were the I. Ordu (Constantinople), with the I. Corps (Constantinople), II. Corps (Rodosto), III. Corps (Kirk Kilisse), and IV. Corps (Adrianople). These constituted 12 active divisions, *plus*, on mobilization, 11 first reserve divisions and 6 second reserve divisions. In Macedonia were the II. Ordu (Salonika), with the V. Corps (Salonika), VI. Corps (Monastir), VII. Corps (Uskub), and the independent 22nd Div. (Kozani), 23rd Div. (Yannina), and 24th Div. (Scutari).

These constituted 12 active divisions, *plus*, on mobilization, 10 first reserve divisions and 3 second reserve divisions. Administratively, the reserve formations of Smyrna, and both the active (VIII. Corps) and reserve formations of Damascus, belonged to this II. Ordu. Under favourable circumstances, and especially if Greece were neutral, these forces, totalling 3 active and 15 first reserve divisions, would be available. In the alternative, they would be available, with some delay in point of time, to reënforce the army in Thrace. The III. and IV. Ordus, with headquarters at Erzinjan and Bagdad respectively, could be grouped as an army of the Caucasus in case of a Russian war, but were practically unavailable for Europe. So also were the forces in Hejaz and Yemen, and Tripoli. Neglecting second reserve formations, therefore, the paper dispositions gave Thrace 23 and Macedonia 22 divisions, to either of which might be added a further 18. But, as usual in Turkish military history, this imposing paper total of 63 divisions represented far more than the real and available strength. Internal difficulties, low transport capabilities, and the necessity of garrisoning almost all parts of Albania and Macedonia to prevent local risings, added to the customary slackness in administration and training and the customary dishonesty in supply and equipment matters, resulted in the putting into the field of two armies which were numerically inferior, unequally trained, and poorly equipped—possessing indeed few assets beyond the solid fighting-worth of the individual Mahommedan Turk.[2]

With all this, however, the prestige of a great Power facing a group of small states, whose mutual hatred and rivalries had only just been composed, stood high, especially in Germany where the positive effects of the Turkish army reforms initiated by von der Goltz and others were overrated. In the Turkish army itself, confidence was unbounded: only a few had their misgivings.

The actual strengths of the two Turkish armies, owing to inexact and defective returns, cannot be stated. But it appears to be true that the Thracian army had no more than half of its nominal strength of 226,000 men, while the Macedonian army short of the VIII. Corps and the Damascus and Smyrna reserves and scattered as it was, can hardly be credited with more than 200,000 of its nominal 340,000, of whom no more than 50,000 combatants were in fact ever assembled on one battlefield.

On the side of the allies, administration being regular and sentiment uniform within each army, the paper strength and order of battle represent realities, and can be summed up thus:—

Bulgarian Army:—Nine divisions (1 Sofia, 2 Philippopolis, 3 Steven, 4 Shumla, 5 Ruschuk, 6 Vratsa, 7 Dupnitsa, 8 Stara Zagora, 9 Plevna) each of two brigades *plus* a reserve brigade formed on mobilization. (The regiments being each of 4 battalions, the infantry strength of a division was 24 battalions, *i.e.* that of a normal European army corps, and 2½ times that of a Turkish division.)[3] A 10th Div. and an 11th Div. were formed on mobilization out of surplus reservists and of such Macedonian volunteers as enlisted in the regular forces (these had two brigades each instead of three). There was also a cavalry division. Ration strength of the field armies, about 280,000.

Serbian Army:—Five divisions of the I. Ban and five of the II. Ban, each designated by the regional name (Danube, Morava, Drina, Shumaja, Timok and the Ban numeral, *e.g.* Timok I., Timok II., etc.). The infantry strength of a I. Ban division (four 4-battalion regiments) was two-thirds that of a Bulgarian division and

[1] The possession of one modern ship, the "Averof," gave to the Greeks material superiority over the Turks at sea, and the maritime traditions and aptitudes of their race a certain moral advantage.

[2] Even solidarity within the unit had been seriously shaken by the incorporation, under new conscription laws, of Christians allied in race and religion to the enemy peoples.

[3] The 6th Div. had only two brigades.

not quite twice that of a Turkish. The infantry strength of II. Ban divisions varied, but was usually three 4-battalion regiments. A number of supplementary regiments were formed from excess reservists, III. Ban units, for subsidiary operations. There was a cavalry division. At the completion of mobilization the ration strength of the field forces alone, exclusive of III. Ban units, was 287,000, almost exactly 10% of the population. In the whole war some 450,000 men are supposed to have been mobilized.

Greek Army[1]:—Four active divisions of 9–11 battalions each (equal in number of units, and superior in effective numbers, to a Turkish division). Reserve units forming four weak divisions, each equal to two-thirds of a normal division. One cavalry brigade. Ration strength of the field army, about 110,000.

Montenegrin Army:—A militia organized in four divisions of varying strength. Approximate total of field troops 47,000.

With regard to the proportioning of effort between the two theatres of war, contemporary military opinion, impressed by a sort of primacy which Bulgaria assumed in the league, by the more regular character of her army and her civil administration, and by the nearness of Constantinople to her eastern frontier, argued *a priori* that Thrace was not only the "principal" theatre, but the single important theatre in which practically all military effort should have been concentrated by both sides—a judgment which ignored the relation of strategy to war policy, and one for which in the sequel Bulgaria was destined to pay heavily. For the objective of the war was Macedonia, as von der Goltz had foreseen in 1909 when he increased both the present and the potential strength of the Turkish forces allotted to that theatre. And when conquered, Macedonia would be conquered once and for all, for the possibility of a Turkish counter-offensive to recover the lost province was excluded by the Greek navy as effectually as the possibility of reënforcing Tripoli had been excluded by the Italian navy in 1911. A further important consideration for the allies was the obscurity of the ethnographic lines in central Macedonia. Here the population was neither definitely Bulgarian nor definitely Serbian, and unless the two allies concerned were both represented in the conquering army the absent member would certainly suffer when it came to drawing the frontier-line.

On the other hand, each of the allies had special objects which might, and in some cases did, conflict with the common object. Bulgaria cherished ambitions in Thrace which extended even to Constantinople, and she had to consider the fact that sooner or later the Turkish forces in Thrace would be reënforced not only by their own allotted reserves but also by those, above alluded to, which the Greek navy prevented from going to Macedonia. Further, Bulgaria coveted not only a coast-line on the Aegean but the great port of Salonika itself.

Serbia, on her side, had to consider not only central Macedonia but northern Macedonia and the Sanjak of Novibazar. These provinces would infallibly revolt against the Turkish authority as soon as the Turkish forces withdrew to concentrate for battle in the S., and unless *bona fide* troops of the Serbian Government came to occupy the country, a state of disorder would arise that would equally certainly invite Austrian intervention.[2] Further, Serbia was determined to carve for herself a way to the Adriatic through northern Albania. Greece for her part had a minor objective in Epirus—a region of which the northern limit was vague—and as a major objective Salonika and the Aegean littoral beyond, not to mention more remote objects in Asia Minor.

Montenegro's aims were limited to local expansion southward into Albania and eastward into the Sanjak of Novibazar and northern Macedonia; in both of these directions some conflict of interest with the Serbian Government might arise.

All these things were, in their varying degrees, elements of policy upon which the Allied strategy must base itself if its war aims were to be obtained, and accordingly the military treaty between Bulgaria and Serbia provided for a Serbo-Bulgarian army of 7 Serbian and 3 Bulgarian divisions to invade Macedonia, moving concentrically against the front Uskub–Kumanovo–Kratovo–Kochana, forming the outer contour of the plain known as Ovche Polye which was assumed on both sides to be the natural concentration area of the Turks.

If the road system was judged by the staffs sufficient to permit of the augmentation of the left wing, this was to be made up of 2 Serbian and 3 Bulgarian divisions—a force equivalent to 10 Turkish divisions, while the other 5 Serbian divisions (equal to about 8 Turkish) descended from Vranya upon Kumanovo. If not, the central mass of 5 Serbian divisions was to be flanked on the N. by 2 divisions moving by the Kara Dagh on Uskub and on the S. by the 3 Bulgarian divisions advancing on the front Kratovo–Kochana. In both cases the envelopment of all the forces that the Turks could gather for battle was the object aimed at. It provided also that if the military situation in Thrace required it, troops not indispensable in Macedonia might be transferred thither, and vice versa.

The balance of the Serbian forces (about 3 divisions) were at the free disposal of their Government, and in fact were intended for the conquest of the Sanjak of Novibazar.

The 6 (or 7) Bulgarian divisions remaining were to form the army destined for Thrace.

The rôle of Greece, when she acceded to the league, was by offensive operations from Thessaly to bind as many hostile troops as possible, incidentally occupying the country which it was intended to acquire. The Greek navy was to close the Aegean to Turkish transports. A minor Greek force in the Epirus theatre, and the Montenegrins in northern Albania, were similarly to absorb the attention of the Turkish garrisons (3 independent divisions) and to conquer territory.

On the very eve of operations, however, a drastic change was made (Sept. 28) at the instance of Bulgaria. Instead of 3 divisions, 1 only was to operate in Macedonia, and this was directed to move independently from Dupnitsa in the direction of Seres and Salonika. The striking wing of the allied army—that which, directed upon Shtip, would have come in upon the rear of the Turkish positions on the Ovche Polye—was thereby deprived of a force of about 80,000 men. And Bulgaria, by evading at the last moment an obligation that was not merely part of a military scheme but was included in the basic political treaty of Feb. 29 1912, set op at once an atmosphere of friction which was not likely to help her in her claims to the doubtful districts of Macedonia. Serbia, submitting rather than agreeing, redistriboted her forces, and the strategic deployment and order of battle actually carried oot was as follows:—

Commander-in-chief, King Peter
Chief of the general staff, Gen. Putnik

II. Army	Gen. Stepanovich (28,000 ration strength)	Timok I.[3] and Army troops.
I. Army	Crown Prince Alexander (126,000 ration strength)	Morava I., Drina I., Danube I., Danube II., Timok II., Cav. Div., Army troops.
III. Army	Gen. Yankovich (67,000 ration strength)	Shumaja I., Morava II., Drina II., Morava Brigade, Army troops.
Ibar Force	Gen. Zhivkovich (18,000 combatants)	Shumaja II., Army troops.
Yavor Brigade	Col. Angelkovich (9,000 combatants)	(1 mixed brigade).

The I. Army was cantoned in the Morava valley, about Vranya, with outposts on the frontier. The II. Army on its left (now reduced to one division) was concentrated along with the 7th Bulgarian Div. about Kyustendil, and the III. Army on its right, behind the frontier, on the various mountain routes E. and N. of Prishtina. The Ibar Force lay on the river of that name, just inside Serbian territory, opposite Novibazar. The Yavor Brigade was temporarily held back facing the Serbo-Bosnian frontier. The intention was that the III. Army should advance first and make good possession of Prishtina, and then turn S., leaving one division to hold the captured territory, and with the remainder advance rapidly S. through the Kachanik defile on Uskub, the unattached brigade meantime opening up communication over the Kara Dagh with the Central (I.) Army. This would have initially the difficult task of debouching from the narrow front of the Morava valley, while the sole remaining unit of the II. Army was to advance by Egri Palanka towards Kratovo.

The Ibar Force, and eventually the Yavor Brigade also, were to clear the Sanjak of Novibazar of Turkish garrisons and Albanian bands. The Montenegrins were to coöperate to some extent in this task, but their main effort was to be directed against Scutari.

Mobilization began in all the countries affected on Sept. 30–Oct. 1. Montenegro was the first to declare war, on Oct. 8. Ignoring the declaration of the Great Powers that "under no circumstances would they agree to any change in the *status quo* in S.E. Europe," the other three members of the league presented a joint ultimatum on Oct. 13. Turkey rejected this on the 15th, and on the 17th wnr was declared. By that date the movements of strategic concentration were nearly complete, and several frontier skirmishes had already taken place.

II. The Campaigns in Macedonia and the West.—On Oct. 20, while the Serbian I. and II. Armies closed op on their advanced elements (the I. clearing some high ground beyond the frontier to facilitate the next day's work), the III., which had the greatest distance to cover, marched in several columns on Prishtina. Irregular fighting on difficult ground brought the army close to Prishtina by the 22nd, and the Turks evacuated the town on the evening of that day.

On Oct. 21, the I. Army advanced in three columns: Morava I., Timok II. on the right, with flank guards in the Kara Dagh, fol-

[1] The navy consisted of the "Georgios Averof," a powerful armoured cruiser, 3 old coastal battleships practically modernized, and 16 modern destroyers and other torpedo craft, including a submarine; as against the Turkish strength of 3 small battleships (ex-German), one modernized coastal battleship, 2 light cruisers and 20 effective destroyers and torpedo boats.

[2] The relations of Serbia and Montenegro were not such that the Serbian Government could easily hand over to Montenegro the entire responsibility for the conquest of the north.

[3] The 7th Bulgarian Div. was nominally under the orders of this army, but in fact obeyed orders only from the Bulgarian headquarters.

lowed the Moravitsa valley; Danube I. and Danube II., on the left that of the Pcinja; while Drina I. moved along the watershed between these rivers. The cavalry division was kept back till the infantry should have gained ground in the plain. The II. Army moved on the same day, but very slowly, along the Kyustendil–Egri-Palanka road, with instructions to advance thence both on Stratsin (Stracin) and on Kratovo, gaining touch with the I. Army W. of the former place. Bulgarian coöperation was limited to a movement by one brigade over the mountains towards the upper Bregalnitsa. The rest of the 7th Div. frankly began its march over Jumaya Pass into the Struma valley, heading for Seres.

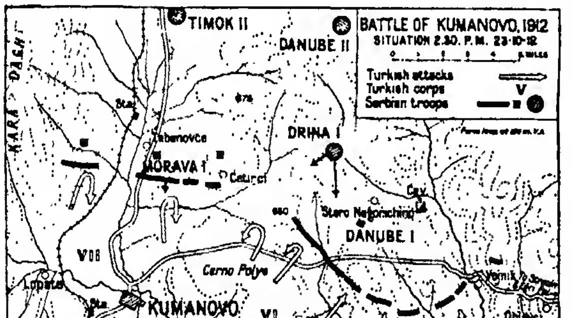
That evening, without having obtained touch either with the II. or the III. Armies, the I. Army halted on the line Tabanovche–Star–Nagorichino, disposed in depth and entrenched, with orders to stand fast on the 22nd and wait developments on its flanks. Resistance so far had been slight, but on the 22nd Turkish forces of some strength were reported at Komanovo.

The Ovche Polye was, after all, not to play the part of Königgrätz. At first, it seems, the Goltz plan of a defensive concentration there, to be followed by radial attacks on divided enemies, was adhered to by the Turks. But when at the last moment it became clear that the Bulgarian effort was concentrated on Thrace, 'Ali Riza Pasha, commander-in-chief in the Macedonian theatre, was ordered to take the offensive. Zekki Pasha, in charge of the three corps grouped in the Vardar region, was at once directed by 'Ali Riza to move forward against the Serbians as they debouched from the mountains.

Of 'Ali Riza's 25 divisions, 3 were scattered between Prishtina and the Austrian frontier, 3½ at Scutari, ½ at Dibra, and 1 at Prizren; 2 opposing the Greek main army in Thessaly and 2 the Greek secondary army in Epiros; 3 in the Struma valley and 1 guarding the railway between Veles and Salonika, making, in all, 16 which were totally unavailable for battle in the decisive theatre.[1] Of the remaining 9, 1 was at Prishtina, 2 in the valleys of the Bregalnitsa and the Zletovska facing Kochana and Kratovo, and 6, forming the main group under Zekki, advanced across the Ovche Polye on the 21st and 22nd, the V. Corps then halting N. of Novoselyani, the VI. N. of Slatina and the VII. N. and N.E. of Kumanovo.

Viewed as a whole, 'Ali Riza's forces, scattered as they inevitably were through the need of holding territory, were reasonably well distributed, in that, though the Turks were in the ensemble inferior in the ratio of 1 to 2½, their handicap on the decisive battlefield reduced itself to the ratio of 1 to about 1½. Had still further economies been practised (in the Struma valley for instance) this handicap might have disappeared. But uncertainty as to Bulgarian movements and dispositions was not yet cleared up. In any case, the seizure of the initiative at a moment when the Serbian I. Army was still cramped and out of touch with its neighbours went far to neutralize the numerical disadvantage.

As a matter of fact, Zekki intended to use the day of the 23rd for closing up his columns and narrowing his front; and, Prince Alexander's intentions being the same, the day would have been uneventful but for the initiatives of subordinates on both sides.



The Serbian Danube I. Div., on the evening of the 22nd, had been tempted to go forward, out of alignment, by the evident tactical advantages of a position farther south. On the morning of the 23rd it was formed in an arc facing S. and S.W., with its left flank on the Pcinja, near Voynik, its centre looking towards Slatina and its right on hill 650, and in that position it was attacked by the heads of 4 Turkish divisions. A fierce battle raged all day on this front, while the other 2 Turkish divisions (VII. Corps) engaged Morava I., N. of Kumanovo with indecisive results, and the remaining Serbian divisions, Drina I. in the centre, Timok II. behind the right and Danube II. behind the left, remained practically inactive, partly in ignorance of what was taking place (the Army Command itself was in the like case), partly because strict orders had been given to stand fast during the 23rd. Only Drina I. came into action towards evening, and the situation was critical when fighting died away and army headquarters at last became aware of the facts. During the night the remaining divisions were urged forward to the battlefield.

Next day they came progressively into action. The stubborn resistance of Danube I. had shaken the attacking power of two-thirds of Zekki's force, and the intervention of Danube II. and the Serbian cavalry division on the 24th completed the work, after hard fighting beyond the Pcinja. And when a few advanced troops of the II. Army from Egri Palanka reached the outskirts of the battlefield, the V. and VI. Turkish Corps, fearing to be enveloped, retreated southward into the Ovche Polye. In the centre, Drina I. drove forward far into the weakest part of the enemy's system. On the Serbian right, the Turkish positions between Cerno Polye and Lipkovo in the foothills of the Kara Dagh fell to the attack of Morava I. and Timok II. in the afternoon. With a loss of some 4,500 killed and wounded (nearly half of these in Danube I.), the Serbians had won the first great battle of the campaign. But it was not a *bataille sans lendemain* as the Serbo-Bulgarian convention had intended it to be. Neither the III. Army, which coming in from Prishtina was still two days' marches distant, nor the II., which consisted effectively of one division only, could help to make it so. And in consequence no real pursuit was made, the I. Army halting and entrenching on the ground it had gained. Actually, a pursuit would have closed the campaign, for the Turkish retreat had converted itself into a rout. Even Uskub was evacuated, and the force barring the Kachanik defile against the III. Serbian Army withdrawn.

For some days the Serbian G.H.Q. continued to keep a tight rein on its armies, grouping them principally for a battle against the "Turkish main army" presumed to be about Veles–Shtip. The cavalry division advanced to St. Nicholas, a point equidistant from these two towns, while Timok I. (II. Army) passed Kratovo and moved on Cerni Vzh, which was not captured till the 26th. The I. Army followed carefully to the latitude of Gradishte, while the III., parts of which—for the sake of earlier contact with the I.—had used routes E. of Kachanik that had now become eccentric, moved up slowly on its right. Drina II. was left at Prishtina to secure the country and coöperate with the Ibar Force, while Uskub was held by Morava I. So difficult was the country and so imperfect the liaisons that it was not till the 29th that the deployment of the I., II. and III. Armies across the Ovche Polye was complete.

By that time the Turks had long evacuated the right bank of the Vardar. The remains of the VII. Corps from Uskub had gone to Tetovo and part of the V. Corps had retreated down the Vardar, but the bulk of the V. and VI. Corps had retired through Veles towards Monastir and were preparing to offer a new resistance in the Babuna Pass.

But the Serbian G.H.Q. had now gleaned many details of the Turkish rout, and, assuming Zekki's army to be reduced to a remnant which could be crushed between a single Serbian army and the Greeks, it made entirely new dispositions on the 29th. To aid the Bulgarians in the siege of Adrianople, it sent the II. Army, and actually added to it Danube II. in replacement of the Bulgarian 7th Div. which continued its way down the Struma.

To penetrate Albania and gain the desired foothold on the coast, the III. Army (reduced to Drina II. and Shumaja I. and army troops) was sent eastward on Oct. 31.

The I. Army, now consisting of Morava I., Drina I., Danube I., Timok II., Morava II. and the Morava Brigade, was to pursue the Turkish army and complete its ruin, in coöperation with the Greeks.

Meantime, the conquest of the Sanjak of Novibazar and of northern Kosovo had been practically completed. From Oct. 10, Montenegrin forces under Gen. Vukovich had been operating from the inner part of their country towards Plevlye, Byelopolye, Berane, and Gusinye. On the 19th, the Ibar Force under Zhivknvich (Shumaja II.) had advanced in several columns which, with more or less irregular fighting and one or two critical moments, had converged on the town of Novibazar and captured the Turkish works on the surrounding heights by the evening of the 22nd. On the 23rd, Novibazar was occupied, and the work of hunting down the dispersed enemy and their Arnaut auxiliaries began. On the 28th a force from Novibazar, in concert with a detachment of the III. Army from Prishtina, captured Mitrovitsa. In the extreme N. the few Turkish troops available were forced, under pressure from the Montenegrins and the Serbian Yavor Brigade, to concentrate at Plevlye; there they were attacked on the 29th and driven over the Austrian border. On the 30th Ipek (Pech) fell to the Montenegrin southern columns. Thenceforward the troops in these regions were only employed on police duties; but their withdrawal to other theatres of war was, in view of a possible intervention by Austria-Hungary, considered undesirable.

The Greek campaign opened on Oct. 18. The 4 active divisions of the Greek army and 3 of the new divisions (5th, 6th, 7th) formed the main army in Thessaly under the Crown Prince Constantine, whose chief-of-staff was Gen. Danglis. The 8th and 9th Divs., composed almost entirely of reservists and volunteers, constituted the Epirus Army under Sapundjakis.

[1] These outlying divisions are catalogued here as such. But their strengths were in reality very unequal.

The Turkish force opposing each of these amounted to about 2 divisions. So small an allotment on the Thessaly front can only be explained on the assumption that the Turks supposed the Greeks to be at the same level of efficiency as in 1897. If so, they were deceived. From Trikkala the Greek 5th Div. moved on Diskata and the upper valley of the Vistritsa. Two divisions (2nd and 3rd) advanced into the salient W. of Tyrnavos and occupied Damasuli, and moved N. to clear the way for the 1st and 4th Divs., which from Tyrnavos moved directly on Elassona by the Meluna Pass. The 6th and 7th Divs., still imperfectly organized, followed on in second line.

On the 19th Elassona was captured with little difficulty, the main Turkish position lying farther N. in the defile of Sarandoporon which traverses the mountains lying between the Xeria and the Vistritsa basins. On the 20th and 21st, the Greek divisions, which had converged on Elassona for the battle that had been expected there, were redeployed, and on the 23rd the attack was delivered by all five. The 5th from Diskata and the 4th from the Xeria, uniting in the Vistritsa valley, marched on Serfije, throwing out a flank guard to Grevena, while the 1st, 2nd and 3rd Divs. attacked the defile frontally and threatened its rear by way of Vlaholivadia. The much smaller Turkish force was routed with a loss of 20 guns and many prisoners, and (what was more important) the Greek army gained self-confidence as well as local victory, at a cost of some 1,300 casualties. Part of the beaten force retreated from Koziani on Monastir, the remainder on Verria, and the Crown Prince occupied Koziani on the 25th.

In view of the urgency of occupying Salonika before the Bulgarians arrived, the Crown Prince decided to leave only flank guards (5th Div. N. of Koziani and light troops N. of Grevena) facing the Monastir direction, while the remainder, reënforced by the 6th Div., pushed on to Verria, and the 7th Div. worked along the coast towards Katerini. These moves were successfully carried out: the 7th Div. gaining touch with the fleet on the 28th, occupied Eleutherochori and there created a new base, while from Verria the main army turned sharp N. and seized Vodena, the 5th Div. at the same time advancing to Banitsa by Khailar. This ingenious manœuvre placed the five divisions of the main body on interior lines with a base on the sea and a strategic flank guard on either hand (Nov. 1). But the situation was nevertheless critical for the Greeks, for Hasan Tahsin had drawn in forces from the Struma valley and was in position facing W. at Yenije Vardar, while Djavid Pasha at Monastir had assembled an effective force from troops that had come in both from the Kumanovo and the Sarandoporon battlefields, and was moving out to attack the 5th Division. The Serbian cavalry descending the Vardar had not yet passed the defile of Demir Kapu the Serbian armies were being rearranged for the new movements above detailed, and even the I. Army was scarcely beginning its movements against the Babuna Pass. As to the Bulgarian 7th Div., the last thing desired by the Greek headquarters was an energetic advance of this force to forestall them at Salonika.

On Nov. 2 and 3, while Constantine attacked the Yenije Vardar position without success, Djavid fell upon the 5th Div. and drove it with heavy losses to Khailar. Simultaneously, the Greeks from Grevena, who had reached Kastoria, were forced back. But on the 4th, before these flank guards had been sufficiently beaten, the 7th Div. from Eleutherochori had forced the passage of the Kara Azmak and were threatening to interpose between Hasan Tahsin and Salonika. A renewed frontal attack at the opportune moment broke into his position at Yenije Vardar, and, threatened on all sides, the Turks withdrew into Salonika, where their commander and 29,000 men surrendered to Constantine on the 9th.

Next day the 7th Bulgarian Div.[1] arrived and claimed the city for Bulgaria. An open rupture between the allies was only avoided by the establishment of a *condominium*.

The Greek army was then regrouped. The 1st, 2nd and 7th Divs. remaining for political reasons E. of the Vardar, the 3rd, 4th and 6th Divs. were concentrated at Vodena, with the 5th at Khailar and the Grevena force on the Kastoria road, in readiness for an advance on Monastir in concert with the Serbian I. Army.

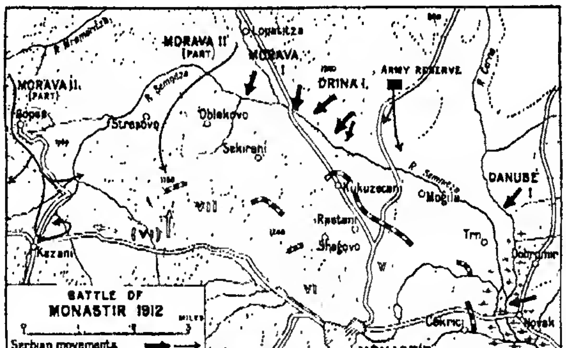
This army had begun its advance on the mountains surrounding the basin of Monastir on Nov. 1, Morava I. and Drina I. moving directly from Veles, and Danube I. from Shtip by Krivolak[2] on Prilep, while Morava II. from Tetovo marched S. on Gostivar. On the Prilep and Kichevo routes respectively, the Turkish V. and VII. Corps were rallied to dispute the passes while the VI. Corps assembled at Monastir.[3]

The forcing of the Babuna Pass above Prilep was a long and difficult business, which fell on the central column alone, as Danube I. and Timok II. had to await bridging equipment before they could cross the Vardar. It was not until Nov. 5 that Prilep was reached, and then a further pause was thought necessary to reassemble the units, scattered by mountain fighting, as well as to allow the two flank columns to come up. On the same day, however, hearing of the crisis on the Greek front, and arguing that it was both necessary to relieve pressure on the 5th Greek Div. and also possible to advance without undue risk against the Turks remaining in front of Monastir, the Serbian G.H.Q. ordered a tentative offensive towards Alince. This, carried out on the 6th by a part of Drina I., soon developed into an unintended battle, in which Morava I. and the cavalry division[4] were called on to join. But the result of a day's fighting, which was marked by initiative and combination of effort in the subordinate commanders, was to hustle the Turkish V. Corps back to the environs of Monastir. A rash advance of the two divisions into the midst of the enemy was only prevented by stringent orders from G.H.Q. to halt and await the coming of the two flank columns. Of these, Morava II. had successfully driven back the Turks from Kichevo on Nov. 5, but was obliged to halt in order to organize its line of supply Gostivar–Tetovo–Uskub, and the left column was only just beginning the passage of the Vardar at Krivolak. Still doubtful of the real situation on the Greek front, Prince Alexander, in agreement with Putnik, was determined not to fight the battle of Monastir till he should have all his forces in hand.

The assembly of the forces for battle on the line Mramoritsan–Podine—Dobrusovo was to be completed for Nov. 14.

The Turks also prepared for battle. Leaving only a few troops in front of Verria and of the Greek 5th Div. and Grevena force, Djavid Pasha brought back the rest of the VI. Corps to join 'Ali Riza at Monastir, where what remained of the V. and VII. were concentrated. The total combatant strength was about 40,000. The position taken up lay S. of the line of the Semnitsa and thence along the marshy bank of the Cerna, its eastern half lying on the plain and its western half on the heights. The V. Corps occupied the plain from opposite Novak to Kikuricani, with its centre of gravity on the Prilep road. The VII. Corps occupied the mountain sector; and the V. Corps was in reserve at Monastir.

The Serbian plan was to attack the Kikuricani front and the heights abutting on the plain with Morava I. on the right and Drina I. on the left, to attack and outflank the Turkish left wing on the mountains by means of Morava II. which was coming down from Kichevo, and to do the same on the right of the defence with Danube I. and the cavalry division operating at and S. of Novak. Timok II. was to be in reserve behind the centre. The necessity of maintaining at all costs the single supply route of the army—that through Prilep to points on the Uskub–Salonika railway—no doubt imposed a plan of



battle that was to all intents and purposes frontal, for the projected movements of cavalry on Resna and over the Cerna could hardly be regarded as serious attempt at envelopment.

The battle, projected for Nov. 14, was ordered to be postponed till the 17th. But on the 15th, as the divisions were getting into position, part of Morava II., carried away by its own ardour, launched a night attack on height 1,150 S. of the Semnitsa. The enemy was well prepared, position after position had to be stormed and it was not till the afternoon of the 16th that the detachment secured the height, at the cost of heavy losses. Meantime the rest of the army, according to orders, was merely making its final reconnaissances. On the 17th, the four battalions of Morava II. had to resist, still without help from the rest of the army, a series of heavy counter-attacks delivered by the VI. Turkish Corps under the energetic Djavid.[5]

The battle of Monastir, which was finally launched on the whole front on the 18th, will long be studied for its tactical incidents, but as an ensemble it is sufficiently described by saying that the resistance of the half division of Morava II. absorbed so much of the

[1] This, as has been mentioned already, moved down the Struma valley, with a detachment on that of the Bregalnitsa. The latter rejoined by way of Strumitsa, in the last days of October. Another detachment by the Mesta valley, marched on Drama. These columns met with no serious resistance.

[2] Whence the cavalry with infantry support was sent to seize Demir Kapu.

[3] Part of this force took a share in the attack on the 5th Greek Div. at Banitsa.

[4] Which had been relieved on the Vardar by Timok II.

[5] Morava I., however, sent some reënforcements on the afternoon of this day.

fighting effort of Zekki's[1] reserves that the frontal attack of Morava I. and Drina I. succeeded with little difficulty.

Threatened by the Greeks—now again advancing on Florina—and pursued on front and flank by the converging divisions on the battlefield itself, the Turkish army broke up entirely. Half of it was killed, wounded or captured, the other half, in units or small parties, made its way to the only friendly stronghold now remaining open—Yannina (Janina) in Epirus. The victory was completely decisive, and all that remained for the allies to do in the western theatre was to carry out the march to the sea, to occupy and police the region of Okhrida-Dibra-Elbasan, to reduce the two fortresses of Scutari and Yannina (the last refuges of Turkish authority), to ensure against Austrian intervention (for which purpose the main body of the I. Army was moved back to Uskub after a few days' rest)—and to come to an agreement amongst themselves as to the division of the spoil.

On Dec. 3, Serbia and Montenegro joined in the armistice signed that day between Bulgaria and Turkey. Operations in Macedonia and northern Albania therefore came to an end. Greece, however, did not sign, and continued her operations, though these were in the nature of exploitation rather than of fresh effort, except in Epirus, where operations against Yannina were in progress.

Owing to the necessity of garrisoning Epirus, the Turks had normally maintained two divisions in this theatre. These, and the nature of the country were quite sufficient to make the progress of the Greek secondary army (Gen. Sapundzakis, 8th and 9th Divs., both newly formed) a slow and difficult matter. From the opening of hostilities to Nov. 3, the Greeks were employed in clearing the Luros and Prevesa region. This done, the formidable Pentepigadia defile was attacked, and after four days' fighting cleared (Nov. 8). Sapundzakis then advanced to the outskirts of the fortress of Yannina (Nov. 10), while a column of irregulars from Metsovo in Thessaly and another small detachment from Santi Quaranta came in on his flanks to assist in establishing a loose blockade. But this was the limit of his offensive possibilities, and the weather presently brought operations to a close for the time being.

During the winter, however, the greater part of the field army which had completed its task in Macedonia was brought round by sea via Salonika. Active operations began afresh in the early spring. With adequate numbers and material resources, the Crown Prince was able to deliver a successful general assault on March 5 1913, and the Turkish garrison, numbering about 30,000, wounded and unwounded, surrendered next day.

No further fighting occurred in the Albanian theatre, though the Greeks on the S. and the Serbians in the N.E. attempted without success to round up the few Turkish forces, rallied by Djavid, which had escaped from the catastrophes of Monastir and Yannina.

III. The Campaign in Thrace.—Through the change of plan which Bulgaria forced upon her ally on Sept. 28, Thrace became for the public, military and non-military alike, the principal theatre of war. Nevertheless, the actual plan of campaign of the Bulgarians still remains obscure—all that is known being the fact that the first successes caused it to be abandoned. On the Turkish side, equally little is known with certainty as to the original project, though it is probably safe to say that this consisted in a defensive concentration of the I., II. and IV. Corps on the line of the Ergene and of the III. Corps at or in rear of Kirk Kilisse, with the fortress of Adrianople and the works of Kirk Kilisse acting as breakwaters in front. The scheme, whatever it was, was abandoned at the last moment in favour of a general offensive, as in Macedonia. In these conditions, the facts must interpret themselves, at any rate in the initial stages.

Leaving the 7th Div. on the Macedonian side, the Bulgarians formed three armies between Philippopolis, Trnovo-Seimen, and Yamboli, the latter with especial precautions of secrecy. The II. Army (Gen. Ivanov) on the right, concentrated the 8th and 9th Divs. about Trnovo-Seimen, and the 2nd between Philippopolis and Haskovo. The I. Army in the centre (Gen. Kutinchev) concentrated between Nova Zagora and Kizil Aghach, consisted of the 1st, 3rd and (newly formed) 10th Divisions. The III. Army (Gen. Radko Dimitriev) on the left, or rather the left rear, about Yamboli, consisted of the 4th, 5th and 6th Divisions. In front of it was the cavalry division, with its main body in line with the main body of the I. Army. The 11th Div. was still in process of formation at Philippopolis.

On the day after war was declared, the ensemble, whatever the objects of its movement may have been, began to move—the I. and III. Armies southward and the II. south-westward on Mustafa Pasha (8th and 9th Divs.) and due S. on Kirjali (2nd Div.). Siege artillery was entrained at Sofia for Trnovo-Seimen on the 17th. On the 19th, the 8th Div. on the right of the Maritsa, and the 9th on the left, seized Mustafa Pasha, continuing their progress on the 20th. On that day, the 2nd Div. reached Kirjali on the Arda, while the I. Army crossed the frontier—3rd Div. on both sides of the Tunja, 1st Div. on its left, and 10th in rear, all moving due south. On the 21st and 22nd the same movements continued, while the III. Army in its turn entered Turkey at Ojaköi and Topchular, and the 2nd Div. turned E.S.E., heading for Demotika.

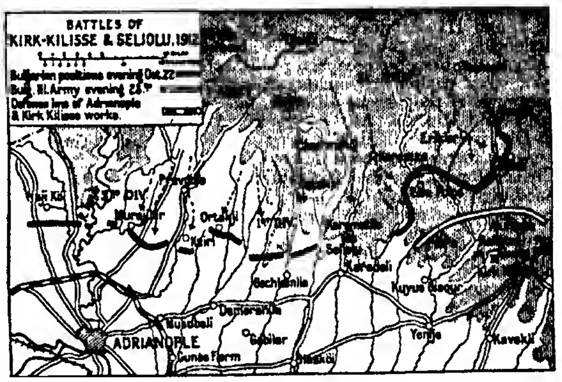
[1] 'Ali Riza had left Monastir, and Zekki was in general command on the field.

On the 22nd the first serious engagements took place in front of Adrianople. That fortress, with modernized permanent works, and a main defence line studded with infantry redoubts farther out and a full interval-organization, had a very considerable perimeter. It was naturally divided by its four water-courses (Upper Maritsa, Arda, Lower Maritsa, Tunja) into four sectors. On the Lower Maritsa-Tunja sector the 3rd Div. of the I. Army was advancing on the Tunja-Upper Maritsa, the 8th Div. (II. Army); and on the Upper Maritsa-Arda front the 9th, also of the II. Army. The last named, advancing S.E. from Kadiköi and Buldurköi was violently counter-attacked. Each side extended southward in search of the other's flank till the Arda was approached. But the combat was really decided by the intervention of the 8th Div. artillery on the other side of the Maritsa. Enfiladed, the Turks retired to their prepared line. Counter-attacks on the 3rd Div. moving down E. of the Tunja had the same result. Thus the process of investing Adrianople began at the very outset, three out of eight divisions available in the theatre of war being employed in it.

In the Tunja-Upper Maritsa sector the principal work of the main line was a group formed round Chiftlik-Ekmechiköi which has been compared to a "Feste." A group of the same character (Papas Tepe) occupied the ridge between Upper Maritsa and Arda, a fortified village barred the Ortaköi road in the Arda valley itself, and a third "Feste" had been constructed on Kartal Tepe. Similar groups of works at Pashachajir and Gunes Chiftlik continue the line of defence between Lower Maritsa and Tunja, merging in the line of the old permanent works at Fort Kuru Cheshme. The operations round Adrianople will be summarized later.

The movement of the I. Army brought only its 3rd Div. directly into contact with the Adrianople defences, the remainder (still with the 10th Div. in rear) aiming at the line Deremanlia-Kukiler. On its left the cavalry division, after several engagements on the 19th, 20th and 21st about Vaisa and Tashli-Muselim, found itself strongly opposed at and E. of Seliolu on the 22nd, on which day also the leading troops of the 1st Div. came in contact with important Turkish forces in front of Seliolu and Gechkenlia. At this time the 3rd Div. was fighting astride the Tunja at Büyük-Sinailcha-Murajilar-Tausan-Ortakji.

Instead of concentrating behind the Ergene, the Turks were in fact advancing northward to battle in accordance with the same general order that had sent Zekki to Kumanovo. The army in Thrace, commanded by Abdalla Pasha under the higher direction of Nazim Pasha, the Minister of War, consisted of the I., II., III. and IV. active corps and of a number of reserve divisions which were only assembled slowly, forming a XV., XVI., XVII. and XVIII. Corps.



The original concentration points were for the I. Corps Yenije and Kavakli, for the III. Corps, II. Corps and IV. Corps (in that order from N. to S.) the zone Bunar Hissar-Lule Burgas, for the XV. Corps (garrison) Adrianople, while the XVI. Corps was to hold the middle Ergene and the XVII. and XVIII. Corps to constitute themselves behind Lule Burgas. In reality the assembly of the four active corps took place at Kirk Kilisse (III.), Yenije and Kavakli (I.), Karali (II.), and Havsa and Kuleli (IV.), with a cavalry division in front of the centre.

At Adrianople, the XV. Corps was duly formed but the XVI., XVII., XVIII. were far in rear and in an embryonic condition, the XVI. indeed never being formed as such.

From these positions the four corps advanced on the 21st and 22nd in accordance with the order to take the offensive, and two encounter-battles ensued, one of which, the engagement of the Bulgarian I. Army, is generally called the Battle of Seliolu, while the other, the first conflict of Radko Dimitriev's III. Army with Mahmud Mukhtar's III. Corps, bears the name of Kirk Kilisse.

The front of the Battle of Seliolu is defined, roughly, by the line Keremetlia—N. of Seliolu—N. of Gechkenlia—S. of Erjali-Ortakji-Kaipa—(at which point it joins the front of the 3rd Div. beginning the envelopment of Adrianople). Heavy fighting on the 22nd and 23rd (of which the most notable incident was a night-attack that

penetrated the Turkish front between Gechkenlia and Seliolu) brought the Bulgarian army victoriously to the Deremanlia–Kukiler-Gerdeli road by morning on the 24th. The Turks had disappeared. Owing to events on their right, they had given up their somewhat disjointed efforts to defeat the Bulgarian centre, and retired in a direction or directions which the victors were unable to determine.

Kirk Kilisse was a route-centre of importance, with a line of barrier works, partly permanent, on its N. side. Von der Goltz had intended that it should play the same part on the right flank as Adrianople on the left. Although the permanent works were few, and inferior to those of the great fortress, the natural positions afforded by spurs of the Istranja Balkan gave the place advantages of site which were lacking at Adrianople. The Bulgarians, on their side, allocated a whole army to the task of dealing with it, by investment, brusque assault or regular siege, or a combination of those methods.

Partly in order to develop the necessary frontage from the outset (in case of battle between Kirk Kilisse and the frontier), and partly in order to utilize the routes to the best advantage in a country much more difficult than that traversed by the other armies, Radko Dimitriev had formed his two leading divisions into four brigade columns—(*a*) ½ 4th Div. from Ojaköi on Keremetlia (liaison with I. Army); (*b*) ½ 4th Div., followed by part of 6th Div. by Devletli Aghach and Eski Polos on Petra; (*c*) ½ of 5th Div. with remainder of 6th Div. from Malkochlar by Erikler on Raklitsa and Kirk Kilisse; (*d*) ½ of 5th Div. from Topchular by Almajik on Kadiköi. Of these columns (*a*) became involved in the Seliolu fighting, and took no part in that of Kirk Kilisse.

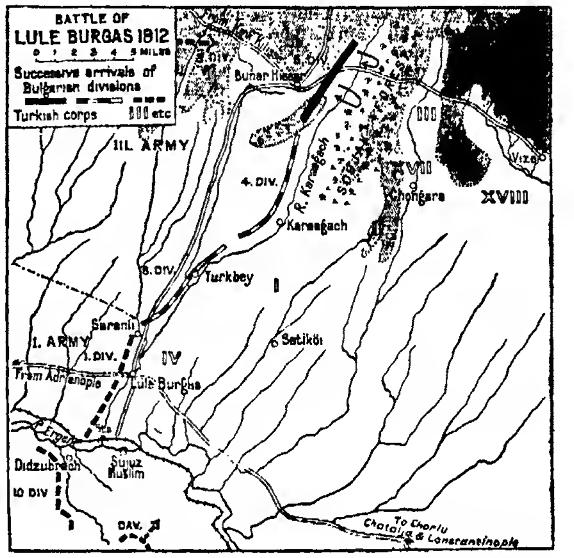
Columns (*a*) and (*b*), forming the strongest part of the army, and also column (*c*) soon met with strong resistance (morning 22nd), and the country, the weather (stormy since the 20th) and tactical incidents making progress uneven, the front at nightfall of the 22nd was very sinuous, the Turks holding pronounced salients at Eski Polos, and also at Almajik, while the Bulgarians had penetrated nearly to Kadiköi in the centre and within 2 m. of Petra on their right. On the 23rd, however, continued pressure on the Kadiköi and Petra fronts forced the Turks to evacuate their salients, and at night the Bulgarian line, with its flanks somewhat advanced, ran roughly E.W. from the heights S.S.W. of Petra, through that village, to height 1,506 N. of Akmacha and thence some distance south-east. From this line, in the night, assaults by parts of the two left columns (5th Div.) penetrated to Karaköi on the one hand and halfway to Raklitsa on the other. And thereupon, worn out by two days' hill fighting and lacking in internal homogeneity, Mahmud Mukhtar's Corps broke up, abandoning Kirk Kilisse and its fortifications, and streamed away in panic. The Bulgarians entered Kirk Kilisse on the 24th and possessed themselves of immense booty, including 55 guns.

Mystified and ignorant of the line of retreat of the enemy, both the I. and III. Armies stood fast on the 24th on their respective battlefields, while the cavalry division was sent out due south. On the 25th the horsemen reached the Constantinople railway at Baba Eski; next, pushing reconnaissances S. and S.E., they found the country S. of the Ergene all clear, but hostile forces between Lule Burgas and Muradli. At the same time the divisional cavalry of the 5th Div. from Kirk Kilisse appears to have established the presence of enemy forces at or near Bunar Hissar.

This information, showing that the Ergene line had been abandoned, and that Abdalla was regrouping his forces and assembling his incoming reserve divisions in the Lule Burgas–Vaisa region, involved a complete change of front for the Bulgarians. Hitherto facing S., they had now to face E., pivoting on the 5th Div. at Kirk Kilisse. And while the necessary movements were being carried out, Abdalla again took the offensive, with the reorganized four active corps, and the XVII. and XVIII. Corps of new formation.

On the 27th the Bulgarian wheel began, but instead of its being carried out on a fixed pivot, the pivot itself was allowed to advance eastward, so that, instead of presenting a united line, the Bulgarians formed a loose echelon, left in advance, which led to successive instead of simultaneous engagements. On the evening of that day, the Turkish III. Corps (Mahmud Mukhtar) on the right, was on the road between Vaisa and Bunar Hissar, the II. at Kara Aghach, the I. at Turk Bey and the IV. partly at Lule Burgas, partly at Sakisköi, the total front between the Ergene and the mountains being about 45 miles. The two new corps were a march in rear. A general offensive had been ordered.

On the 28th, as a natural consequence, an encounter battle began just E. of the Kara Aghach, in the forest of Sujak, between Mahmud Mukhtar's troops and the Bulgarian 5th Div., the latter finally drawing back behind the stream and occupying a line from Chiftlik Teke on the left to Mura Aghach on the right. Thereupon the various Bulgarian columns echeloned back to the right of this division, hastened their march, and part of the 3rd Div. from the Adrianople region was ordered up to support the 5th directly, which by a heavy forced march it was able to do on the evening of the 29th.[1] On the other side, confusion in the command and other causes made the general advance slow and disjointed; the initiative was soon lost, and the battle became one of the parallel fronts along the Kara Aghach. On the 29th (afternoon) the 4th Bulgarian Div. followed by the 6th were already on that line. On the 30th, the crisis of the battle, the I. Bulgarian Army came into action opposite Lule Burgas (1st Div.) and on and S. of the Ergene (10th Div.), while the cavalry returning from Rodosto formed up in advance of the



right flank of the 10th Division. At the same date, the III. Turkish Corps opposite Bunar Hissar and the XVII. Corps on its left, supported by parts of the XVIII. Corps, were still exchanging attacks and counter-attacks with the Bulgarian 5th Div. and part of the 3rd about the W. edges of the forest of Sujak. Against the Bulgarian 4th Div. on both sides of Kara Aghach village, was the II. Corps; against the 6th, about Turk Bey, the I., while the Turkish IV. Corps held the line at Lule Burgas and down to the Ergene against the Bulgarian I. Army. Of this army, however, one division only was involved in the frontal fight, and it became evident to the Turks in the afternoon of the 30th that enough enemy forces remained over to roll up their left wing and interpose between the main body and Constantinople. Accordingly, Nazim issued orders for retreat. During Oct. 31 and Nov. 1, with various tactical incidents, of which the most important was a successful night-attack of the Bulgarians at Turk Bey, the Turks disengaged themselves, beginning from the left, and by the 2nd the three corps on the right were also in retreat.

The victors were too much exhausted to pursue, and again the Turks vanished. The Bulgarian losses out of perhaps 110,000 combatants numbered 15,000; those of the enemy, whose force was probably rather less, are not known with certainty, but are supposed to have been about 25,000 inclusive of prisoners.

Without further resistance the Turks retired into the famous Chatalja lines, a well-fortified position between Lake Derkos on the Black Sea and Büyük Chekmeje lake on the sea of Marmora. However weakened by losses, they could hardly fail to maintain so short and strong a line as this.

On their side, the Bulgarians were tired, far ahead of their supply depots, and losing more and more men daily from sickness. On the other hand, drafts had come up, the 9th Div. replaced before Adrianople by the new 11th joined the III. Army,[2] and the combatant strength of the two armies together was about 140,000. Made optimistic by victory, Savov and his generals determined to storm the Chatalja lines by open force. So confident were they that Savov himself said: "in a week we shall be dining in Constantinople."

On Nov. 17, the Bulgarian infantry advanced and drove in the Turkish outposts and on Nov. 18, the assault took place. It was completely repulsed, with heavy losses, and the Bulgarian command, sobered, took care not to waste its reserves in renewed assaults. Armistice proposals were already under discussion, and the battle was broken off in the afternoon of the assault. On Dec. 3, without further fighting on the Chatalja front, a general armistice was signed, more favourable to the Bulgarians perhaps than their military situation warranted, for it gave them the use of the railway through Adrianople without allowing the Turks to revictual that place.

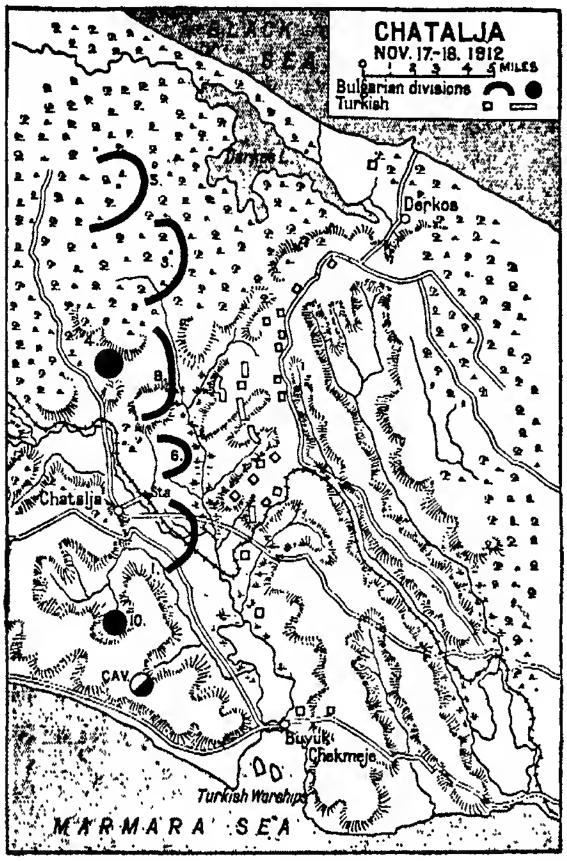
While the main Bulgarian armies were fighting these battles, the 2nd Div. penetrating the difficult Rhodope country had carried out a vigorous offensive in several directions, as the result of which Adrianople was invested on the S.W. side, Demotika and the coast from Xanthi to Dede Aghach occupied, and two Turkish divisions de-

[1] This is all the more remarkable as the Bulgarian I. Army's movements were hampered by fears of a crisis at Adrianople, where a serious sortie-battle was being fought at the time.

[2] Which also received the 3rd Div. from the I. Army in exchange for the 6th.

stroyed in a series of "drives" which ended in the relics of this force being surrounded and forced to capitulate at Ferejik (Nov. 27). (C. F. A.)

IV. Operations in the Spring of 1913.—The London negotiations of Jan. 1913 were abruptly brought to an end when Enver and the Young Turks, fearing that the Government would, under European



pressure, make peace practically at any cost, carried out the *coup d'état* of Jan. 23 (in which the Kiamil Government was overthrown and Nazim Pasha murdered), and denounced the armistice. Hostilities began again (with Greece they had never ceased) on Feb. 3 1913. But they entirely lacked the vigour and dramatic interest of the first campaigns. Practically, the story of the second phase is the final instalment of that of the sieges of Yannina, Scutari and Adrianople. An effort was indeed made by the Turkish field forces in Thrace to debouch from the lines of Bulair and those of Chatalja simultaneously with a view to relieving Adrianople, but after locally heavy fighting the Bulgarians succeeded in holding their own on each of these fronts, and thereafter Adrianople was left to its fate.[1]

The fall of Yannina has already been mentioned. The sieges of Scutari and of Adrianople require, however, a rather more detailed account. (C. F. A.)

The Scutari Operations.—As has been mentioned already, Montenegro was the first to declare war. The first objective was the old Turkish frontier fortress of Scutari, situated at the point where the Drinasa river flows into Lake Scutari, and consisting only of a castle and a few field-works on the hills surrounding the town. The perimeter measured some 28 m., and the average distance of the works from the town was about two. The works had no deep ditches or sunk wire entanglements.

At the outbreak of the war the Turkish garrison was under Hasan Riza Bey, consisted of about 14,000 men (chiefly of the 24th Div.), to which were added, at the last moment, a reserve division from Elbasan under command of Essad, 10,000 strong.

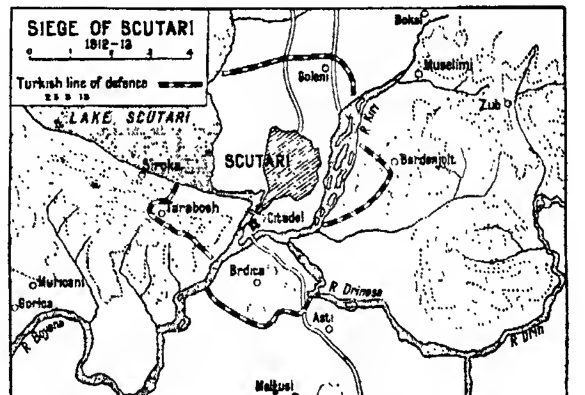
With a force such as this, containing few active elements, only a purely defensive policy was possible. The fortress artillery was weak in numbers and out of date; it consisted (at a generous estimate) of 70 guns (including the divisional field artillery), of which the heaviest were the 12-cm. naval howitzers.

The Montenegrin army stood on Oct. 7, the eve of the declaration of war, as follows: The main body under Crown Prince Danilo (2nd and 3rd Divs., less 9th Bde., 13,000 men and one battalion 12-cm. siege artillery), near Podgoritsa (Podgorica). The southern detachment under Gen. Martinovic (1st Div., 8,000 men and three battalions, 12-cm. guns, one battalion 15-cm. howitzers and two battalions 21-cm. howitzers) was near Virpazar and Antivari. The remainder of the army (4th Div. and 9th Bde., 10,000 men, and three mountain batteries) was at Andriyevitsa (Andrijevica), ready to advance into the Sanjak of Novipazar. The operations of this force are described elsewhere.

The advance on Scutari began on the morning of Oct. 9. The wide separation of the two Montenegrin columns offered the Turks a tempting opportunity of manoeuvre on interior lines, but, for the reasons given above, Hasan Riza was obliged to refrain, and the Montenegrin northern group broke through a series of passively defended positions one after the other. They were, however, so disordered by their victory that they were compelled to halt and refit. On the 19th they recommenced their advance, moving very slowly, and on the 25th halted once more on the Kiri on coming under the fire of the artillery of the fortress. Not until the 28th had they completed their bridging operations; the 2nd and 3rd Bdes. then without awaiting the arrival of the main body carried the hill called Great Bardanjolt. A Turkish counter-attack on the 30th threw them back, inflicting such heavy losses that the Montenegrins fell back to Vratsa and undertook no further advance till February. The group, which had evidently been clumsily led, took up a position between the Kiri and the Lake of Scutari, some 3,000 yd. in front of the Turkish defences.

The Montenegrin southern group moved on Oct. 9 with its 1st and 3rd Bdes. from Antivari to Katrkol, and with the 2nd Bde. from Virpazar along the shore of the lake, both columns meeting with practically no opposition. They then prepared to attack the Turkish advanced position on hill 661. Their siege artillery opened fire only on Oct. 22, and the Turkish forward line was stormed next day with heavy loss. The assailants now found themselves close up against the main defensive line. The northern group having at this time just been driven off the Great Bardanjolt, coördinated attack by both groups was no longer to be thought of. The southern group therefore remained waiting in the position it then occupied.

On Nov. 19 Vukotic, his work in Novipazar completed, arrived with 6,000 men to reinforce the besiegers of Scutari. He himself took



over the command of the whole Montenegrin army, his troops being distributed on both fronts.

Soon afterwards the general armistice was concluded; but Hasan refused to recognize it, as the revictualling of the fortress during the armistice had not been agreed to by the Balkan States. However, only minor skirmishes took place in December and January.

The armistice ended on Feb. 3, and shortly afterwards the attack was renewed in earnest against the Turkish strongholds of Muselimi and the Great Bardanjolt, which had been entrenched and fortified in places by blasting in the rocky soil. The assaulting columns were: (*a*) three battalions (1,500 men) against Muselimi from the N.; (*b*) five battalions (2,100 men) from the N. by hill 200 against the northern slope of the Great Bardanjolt; six battalions (2,400 men) from the N.E. against its eastern slope, and seven battalions (2,800

[1] Shortly before this the only important naval event of the war had occurred. On Jan. 15, the Turkish cruiser "Hamidieh" had slipped out of the Dardanelles, and from that time till the middle of March she cruised in the waters between Malta, Durazzo and the Levant, raiding commerce as opportunity offered.

Meanwhile, the Turkish battle squadron came out of the Straits on Jan. 17, hoping to find the "Averof" absent from the opposing squadron in chase of the "Hamidieh." The Greeks, however, had not committed the expected mistake, and after a long-range duel in which the "Averof" inflicted some damage on the Turkish battleships, the latter returned to the Sea of Marmora, where they remained to the end.

men) from the S.E. against its southern slope. No reserves were allotted.

The attack was delivered after an artillery bombardment of several hours on Feb. 7. The fortified post of Muselimi fell with little resistance, but on the Great Bardanjolt the attack was shattered at the wire. A second assault on the 8th was no more fortunate. On the 9th however, with the aid of a Montenegrin battery that was got up to very close range, the trenches were carried after fierce hand-to hand fighting. The assailants, who had lost 2,000 men, were exhausted.

During the next few days the captured positions were consolidated and field guns brought up. During the main attack the Montenegrins on the N. side had also pushed forward their lines from 3,000 to 1,500 yd. from the Turkish defenses. The lack of siege artillery and of unified fire direction was much felt.

Meanwhile a Serbian contingent under Boyovich had been sent to assist the Montenegrins and complete the investing line between Drinasa and Boyana. Between their right flank and the Montenegrins on the Great Bardanjolt lay a stretch of marshy impassable country. In aid of the attack of Feb. 7 the Serbs delivered a feint-attack on the Tarabosh front, which reached the first Turkish line, but was then driven back. A small Montenegrin column also attacked Tarabosh but broke down at the wire.

South-west of Scutari there had been no change since November. The Montenegrins had made good their casualties and lay some 600 to 700 yd. from the Turkish lines, ensconced in carefully-constructed trenches in the rocks. The Turkish positions here extended for some 4 to 5 m. from the strong point of Tarabosh south-eastwards to the Boyana. The besieging artillery (12-cm. guns and 15 and 21-cm. howitzers) was concentrated in two groups around Oblika and Boboti, whence it could bring a concentric fire to bear on the lofty commanding peak of the Tarabosh. The counter-bombardment of the defense was weak and practically useless, owing to slow and faulty methods of fire.

The ammunition supplies for the Montenegrins, which were sent up across the lake, were amply sufficient for all needs.

The main attack on the Tarabosh began only on March 31, preceded by five hours' artillery bombardment and by feints on the remainder of the front. During the artillery preparation, the infantry took up their positions of assault—one and a half brigades against the northern and western forces of Tarabosh, and one and a half brigades against the south.

On the latter, the assault was repulsed, completely and with heavy losses. The western attack had been more fortunate. The first Turkish position was broken through in one place, but progress was arrested by flanking machine-gun fire and counterstrokes, and everywhere the Turks held their third position firmly. On April 1 the attack was repeated but with no better success, and for the next 20 days, until the capitulation, Turks and Montenegrins here lay facing one another half-way up the slope at a distance of 60 to 70 yd. apart—a situation which recalls in many respects the trench warfare days of the World War. The attack had cost the Montenegrins 1,200 dead.

The Turkish position on the Tarabosh consisted of four lines of trenches, some 30 to 40 yd. apart, and each commanding the one in front of it. The third trench line extended into the country to the east, and the fourth to the north. Behind the fourth line a 7·5-cm. quick-firing gun was posted in a shelter on the crest of the hill. In front of the first and third lines were thick belts of wire. The whole position, which was intended for occupation by a battalion, was in fact held by only 500 men.

The Montenegrins, after their unsuccessful attack of March 31 and April 1, confined themselves to the usual bombardment. The siege artillery was reinforced. The Serbian Gen. Boyovic now took command of the besieging army, but there was considerable dissension between him and Vukotic. On April 16, however, the Serbian troops suddenly left Scutari, and the Montenegrins took over the whole line, under violent artillery fire from the Turks, who, however, made no attempt at a sortie against the thin line of the besiegers. And now, when the fortress seemed quite safe from further assault, it suddenly capitulated on April 22. For some time obscure negotiations had been going on between King Nicholas and Essad, and the brave Hasan Riza Pasha, who had refused to surrender despite the shortage of food, had been assassinated. But already Montenegro was under naval blockade by the Great Powers, who had decided that Scutari should belong to the new state of Albania, and on May 6 King Nicholas yielded and withdrew his troops.

(F. C. E.)

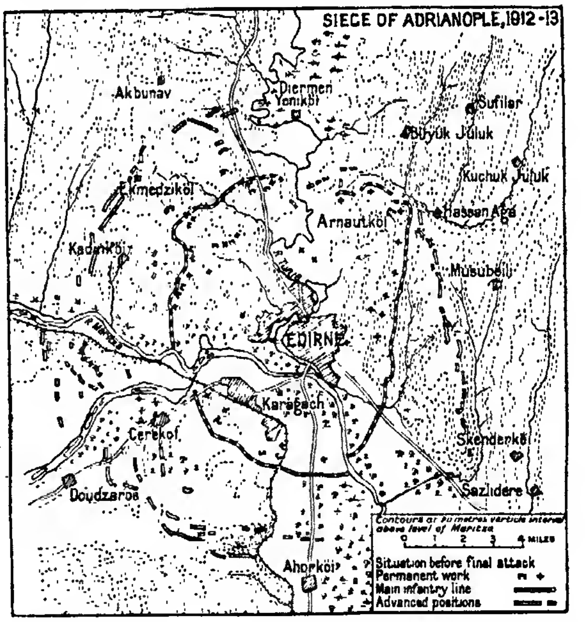
The Siege of Adrianople.—In the first operations of Oct., already described, Adrianople had come within the ambit of the general battle, and it was not till after the Turks had retreated away towards the Kara Aghach line that operations in front of the fortress assumed the typical siege characters of investment and concentric attack.

The general outline of the defences has been described above. But it is important to add that the permanent forts were old and conspicuous, and, except in a few cases where modernization had been actually begun, possessed only brick vaulting that was not proof against 6-in. shell. The only modern works were a certain number of safety-armament batteries distributed in the intervals, of installations for 5·7 mm. close-defense quick-firing guns under armour, and of concrete shelters and magazines. The general principle of defense adopted was that common to Europe in the period before the rise of the "group" or "Feste" idea—that is, the forts were infantry redoubts for close defense and the fighting artillery was entirely in the intervals. Unfortunately for the Turks many of the "redoubts" were open at the gorge. The whole system of the main line was well wired in.

Outside the main position, and coinciding with it only on the N.E. front (left bank of the Tunja), was an advanced position, or rather a discontinuous series of field positions on selected sites astride the saddles of ground which separate the rivers (Tunja and lower Maritsa, Maritsa and Arda, Arda and upper Maritsa, upper Maritsa and Tunja). From these advanced positions the Turks had delivered the first sorties above mentioned and to them they had retired under the pressure of the II. Army's and 3rd Div.'s advance astride the Maritsa and Tunja on Oct. 22. In the days following, the 8th, 9th and 3rd Divs. extended the investment, and the 11th Div. and siege artillery were brought up via Mustafa Pasha, as well as some aeroplanes. Presently parts of the 2nd Div. lately operating in the Rhodope came up, some by the Arda and some *via* Demotika on the S. side. On the other hand, both the 3rd and the 9th Divs. were withdrawn to join the field army in the crisis of Lule Burgas.[1] After establishing their line generally close up to the Turkish advanced positions (in the course of which, on Oct. 25, Kartal Tepe was captured, and Papas Tepe won and lost again), the Bulgarians sat down to await the Serbians, whose II. Army, set free by the victory of Kumanovo, was being withdrawn from the Vardar to assist their allies. Already on Oct. 27 some Serbian troops had arrived and on Oct. 31 Gen. Stepanovich took over the whole W. front of the investment with Timok I. and part of the Bulgarian 11th Div. from Tunja to upper Maritsa and Danube II. between upper Maritsa and Arda. Gen. Ivanov, commanding his II. Bulgarian Army as well as the whole siege force, had his 8th Div. between Arda and lower Maritsa and the 11th with part of the 2nd in the broadest sector, the eastern.

At this point the armistice suspended operations, but Shukri Pasha was not authorized by its terms to revictual his garrison and the defenders continued therefore to consume their resources. After hostilities were resumed on Feb. 3 it soon became evident, from attempts at sorties and from increase of desertion, that the garrison was weakening, and it was decided to force home the attack.

Want of transport resources, however, delayed the preparations till the third week in March 1913, when—parts of the 3rd, 9th and 4th Divs. having been brought into the Bulgarian II. Army from Chatalja—90,000 Bulgarian and 30,000 Serbian infantry were



actually available for the attack, which would be prepared and covered by the 125 Bulgarian siege guns and howitzers of 12 and 15 cm. calibre (the latter, as mentioned above, being capable of penetrating most of the Turkish vaults) as well as some 250 or more field guns. At this period possibly 50,000 of Shukri's original 60,000 combatants were still available for duty. There were 216 field and 178 heavy guns (including some 21-cm. mortars) distributed in the defenses.

[1] A Turkish sortie with the intention of preventing this was, as before mentioned, repulsed.

The E. front was chosen for attack. The preliminary bombardment was carried out on March 24, and in the night of the 24th–25th the whole of the advanced line on the E. front was stormed, on a 6 m. frontage. During the day of the 25th the Bulgarians suffered a good deal in the captured positions, but Gen Ivanov determined to push home the assault on the main position on the night of the 25th–26th, an order which involved an approach march in broad daylight and consequently heavy losses.

The assault was duly delivered in the night, and came to a standstill on the Turkish wire, save at the point where the 10th Bulgarian Regt. of the 8th Div. (brought over from the S. front for the assault) broke into Fort Ayi Yolu, the second work from the N.E. salient of Arnautköi.

At dawn this regiment found itself isolated but in possession of the fort, and the open gorges of the row of forts tempted the audacious commander to strike out right and left along the ridge. Thus he cleared the way for unit after unit held up at the frontal wire, and, growing snowball fashion, the Bulgarian attack, soon joined by accompanying field batteries, cleared the whole line of the eastern forts by 8 A.M. on the 26th. Meantime the Serbians had captured Papas Tepe, though with considerable losses, and at other parts of the front fierce local attacks were delivered. Shukri's position was hopeless, and he surrendered about midday, with some 60,000 men and all his *matériel*. This great triumph cost the Bulgarians on the E. front 6,300 killed and wounded, and on the S. side 1,700, or 8,000 in all, while the Serbians lost 1,000 in the Papas Tepe sector and 400 elsewhere—a total loss to the allies of 9,400.

V. The Second Balkan War, 1913.—The Turkish war having again been brought to a conclusion by a general armistice, a few days after the fall of Adrianople, peace negotiations were resumed in London, and in these negotiations the settlement of peace as far as Turkey was concerned was, it may be said, the least of many preoccupations. Not only was the Balkan league on the point of internal explosion, but the Concert of Europe was trying to create the new state of Albania in the midst of a three-cornered diplomatic contest between Austria-Hungary, Italy and Russia. Further, Rumania was on the point of intervening in order to secure herself against the consequences of Bulgarian aggrandisement, and the internal politics of Turkey became more confused than ever. In these conditions the Peace of London, signed on May 30, lacked every element of reality.

Already Serbia had drawn her western forces into the Ovche Polye area, to dispute possession of the debatable region which Bulgaria claimed, and the II. Army, which had taken part in the siege of Adrianople, was extricated as rapidly as possible lest it be isolated and disarmed in the territory of its allies. The Greeks, who had concentrated the bulk of their forces in roadless Epirus for the siege of Yannina, lost no time in getting them down to the coast and shipping them to Salonika. For their part the Bulgarians used the railway lines Adrianople-Sofia and Dede Aghach-Seres (the latter secured by the conquest of the coastal region by the 7th and 2nd Divs. in the first campaign) to bring most of their forces into Macedonia.

They were deployed along a " line of demarcation " which was a battle-front in all but name. Only one division remained in Adrianople and some militia on the Dobrudja frontier.

The origin of the war, as between Bulgaria and Serbia, lay in the non-observance by Bulgaria of the original treaty stipulation that she should aid the Serbian campaign in Macedonia with 100,000 men. Having failed to fulfil her part, she now claimed the territory about Uskub, Kumanovo, and Shtip in virtue of other clauses of that treaty. This claim Serbia was in no mood to concede, all the less so since her advance to the Adriatic had been forbidden by the Great Powers. As between Bulgaria and Greece, the former's claim to Salonika seems to have had no better basis than a desire to possess it. As already mentioned, the Bulgarian 7th Div., in arriving from the Struma side a few days after the Crown Prince had fought his way into Salonika from the W., had lost no time in publicly claiming ownership, and it was with hardly concealed joy that the Greek Government received and promptly executed a request to transport this division by sea to the Thracian theatre.

On all these matters bargaining might possibly have reached satisfactory solutions, since there was much to justify Bulgaria's claim in Macedonia. But the Bulgarians had skilfully exploited their primacy during the first war to induce the European press and public to regard Serbians and Greeks as mere satellites,[1] and, as is not unusually the case with successful propaganda, they had come to believe in it themselves, fortified in the belief by fulsome compliments addressing them as the " Prussians of the Balkans " and the " Japanese of the West." On the other hand, the Serbs and the Greeks, thus kept out of the banquet, were not only exasperated, but sober as well. When war came in the last days of June 1913, outpost " incidents " were occurring at many points of the line from Salonika to the old Serbian frontier at Vranya. The combatants were fully deployed, and their battle was the first example of the form that has since become typical of national warfare, the front-to-front conflict along a line which stretches from neutral ground to neutral ground and shows no flank. In this instance it stretched from the Danube to the sea.

The Bulgarian scheme of operations, necessarily offensive, suffered from the weakness of having two objectives—the Ovche Polye and Salonika—and being based on two main lines of communication diverging towards the rear—Kyustendil and Seres-Drama. It also suffered from the political necessity of avoiding the outward semblance of an aggression. The scheme, therefore, was to begin with a succession of outpost affrays along the whole line (which could be represented as a provocation suffered), and then to strike vigorous offensive blows (*a*) from Seres towards Salonika, (*b*) from Strumitsa and Radovishta against the Vardar at Krivolak and Gevgeli (Gyevgheli), (the link between the Serbian and Greek armies); and (*c*) a blow from the region of Kochana towards Egri Palanka. The outpost affrays duly occurred and the real offensives were launched on June 30.

At the opening of the Bregalnitsa battle, the forces were thus disposed:—

Bulgarian Army. Commanded by Gen. Radko Dimitriev.[2]

I. Army (Kutinchev) (Vidin-Berkovitsa front).	9th Div.; one brigade each of 5th, 8th, and 14th Divs.; 13th Div.
V. Army (Petrov) (Pirot-Vlasina front).	1st Div.; main body 5th Div.; main body 14th Div., and one brigade 10th Div.
III. Army (Toshev) (Kyustendil).	12th Div., 15th Div., and main body 4th Div.
IV. Army (Korachev) (Kochana-Radovishta front).	Volunteer brigade; one brigade 4th Div.; 7th Div., main body 8th Div.; one brigade 3rd Div.; main body 6th Div.; 2nd Div.
VI. Army (Ivanov) (Strumitsa-Seres front).	Main body 3rd Div.; a volunteer brigade; 11th Div.; one brigade 10th Div., and one brigade 6th Div.

(The divisions 12 to 15 were new formations, much weaker than the divisions 1 to 9; the 10th and 11th Divs., created in Oct. 1912, were of intermediate strength.)

Serbian Army. Commanded by Putnikas, Chief of General Staff.

II. Army (Stepanovich) (Danube to Vlasina).	Third Ban garrisons of Zayechar and Knyashevats. Timok I., Shumaja II.
I. Army (Crown Prince) (from the old frontier to Car Vrh, astride the Egri Palanka road).	Danube II., Danube I., Shumaja I.
III. Army (Yankovich) (along the Zletovska and the lower Bregalnitsa with detachments at Krivolak and Gevgeli).	Drina II. Morava II. Morava I., Timok II. Montenegrin contingent, Cavalry division.

Greek Army. Commanded by Constantine (since March 18, King of the Hellenes).

(Front: Gevgeli	Left group	3rd and 10th Divs.
on the Vardar	Centre "	4th and 5th Divs.
to the	Right "	1st, 6th and 7th Divs.
Struma mouth.)	Reserve	2nd Div.

(The 10th Div. was an improvised formation.)

In addition, to deal with Albanian troubles, each of the allies retained considerable forces in the mountains; including the main body of the Montenegrin army.

Beginning on June 30, the Bulgarian II. Army drove the Greek front back all along the line till it lay S. of Gevgeli—N. of Langaza—W. of Struma mouth. The Bulgarian IV. Army broke in between the allies and captured Krivolak with its left, while its right, along with the III. Army, attacked the Serbians along the whole Bregalnitsa-Zletovska line, which was forced. On the Egri Palanka front the Bulgarian IV. Army similarly drove in the Serbian I. Army's outposts.

But the Serbians, and also the Greeks, were disposed in considerable depth, and the Bulgarian soldier had little heart for the offensive once it became evident that the enemy was determined to fight. By the night of July 1 the offensive had died down, and it was the allies' turn to counter-attack. At this moment the Bulgarian-Serbian battle line ran approximately through Krivolak-Dragoyevo-Shtip line of the Bregalnitsa and lower Zletovska-Raychani heights-Gorni Posadnik-Redki Buku-Car Vrh-heights E. of Egri Palanka-heights W. of and parallel to the frontier-headwaters of river Pcinja. At the apex of the Serbian salient the Bulgarians had obtained a firm hold on Car Vrh.

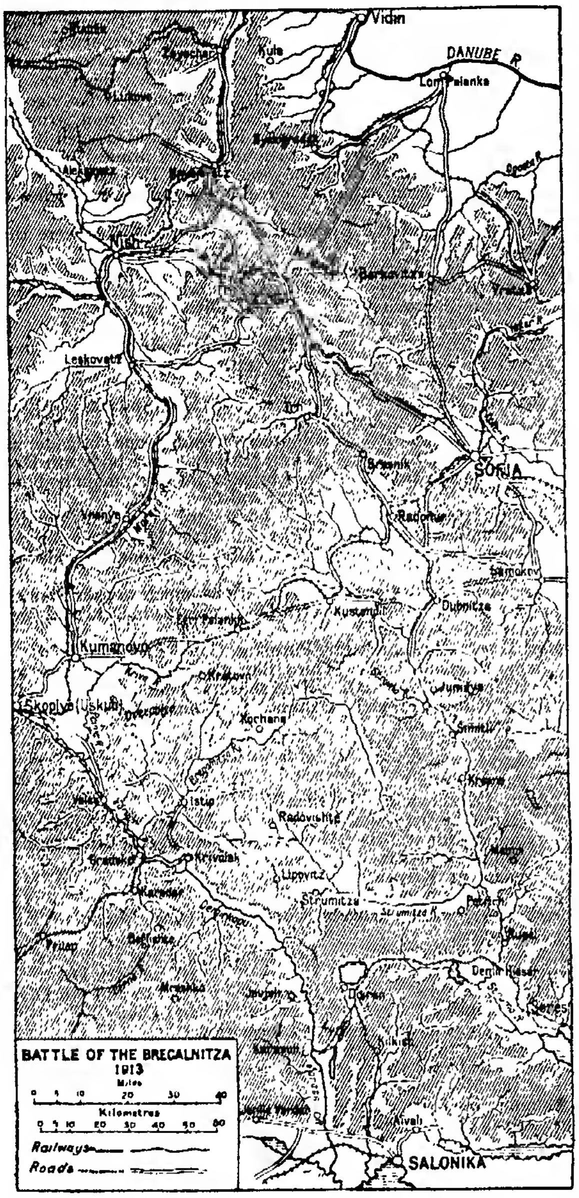
Initiated on July 2, and developed on a large scale on the 3rd, the counter-attack of the Serbian III. Army broke through the Bulgarian line between the Zletovska and Redki Buku inclusive, hustling the defenders back on the 3rd and 4th to the upper Bregalnitsa. Mean-

[1] For example, a British officer lecturing at the staff college on his return from Thrace told his hearers that the Bulgarian 7th Div. had remained in the Macedonian theatre to stiffen the Serbs—an extraordinary travesty of the facts.

[2] Gen. Savov had resigned, not being in agreement with the war policy of the Government.

time the Bulgarian forces between Shtip and Krivolak were slowly driving back Timok II. to the Bregalnitsa, but it was now too late for this to influence either the main battle or that of the Greek front.

On the latter, the Bulgarian advance had come to a standstill, as soon as King Constantine had brought up his reserves, and the



counter-offensive opened on the 3rd. His left (10th and 3rd Divs.) retook Gevgeli, his centre (4th, 2nd, 5th) Kilkish, and his right (1st, 6th, 7th) drove back the Bulgarian left on Nigrita and also eastward on the Seres road (July 3–4). On July 7 the Greek right reached the Salonika–Drama railway, and their left from Gevgeli carried the pass over the Belashitsa which leads to Strumitsa. Thus Ivanov was cut off from the railway, and his only line of retreat lay up the narrow Struma valley to Jumaya.

Yielding to necessity, the Bulgarian forces on the Vardar withdrew, ere it was too late, into the Belashitsa valley, while those pursuing Timok II. on the lower Bregalnitsa halted and drew back.

The opportunity which thus presented itself to the Serbian III. Army of interposing between Ivanov and Bulgaria led to a regrouping of the Serbian forces for the benefit of this army, which, pursuing its advantage, drove back its opponents towards the line of mountains in the upper Bregalnitsa bend (Obozna-1340-Grlena).

But the Bulgarians, in order to relieve pressure and to keep their hold upon Western opinion, seized the initiative again while the regrouping was in process and the Greeks had hardly yet entered the Struma and Strumitsa valleys.

Their new offensive was twofold—local attacks by the I. and V. Armies on all the routes leading into Old Serbia, and heavy counter-attacks on the front of the Serbian I. Army. The first, made with columns of varying strengths on the routes leading to Zajechar, Kynashevats, Pirot and Vlasina, was repulsed by the Serbian II. Army after some initial successes, and was over by July 10. The second was more serious, and it seems that the process of building up the strength of the Serbian III. Army opposite Kochana was not only suspended but actually reversed to cope with a crisis. Finally, however, the Bulgarians were repulsed here also, and retired to the line of frontier mountains (Golemi Vrh–Bozderitsa–Rujan–Sivakobila), more or less in touch with the right of the forces in the mountains of the Bregalnitsa bend.

By this time the Greeks were in possession of the Strumitsa basin and had made some progress up the Struma. But Ivanov had obtained an opportunity that he could not have gained by his own efforts to extricate the various forces of the Bulgarian left which were scattered from the Vardar to the Struma.

The new allied offensive, therefore, begun all along the Serbian line on the 15th, and starting on the battle-front above mentioned (Golemi Vrh–Sivakobila–Obochna), resolved itself into a series of local combats with the object of cutting off as much as possible of Ivanov's rearguard detachments and of making strategic connexion with the Greek left at Pehchevo. At this stage, indeed, bolder strategy was hardly required, for already Rumania had declared war on Bulgaria and had begun an unopposed march on Sofia, while the Turks at Chatalja and Bolair, ignoring the Treaty of London, reoccupied Adrianople without firing a shot.

Yet this relative inactivity of the Serbs gave the Bulgarians one more opportunity, which they seized. Using a manoeuvre which was destined to become a familiar practice of strategy in the World War, but, at that date and in that country of mountains and primitive communications, was conspicuously daring and novel, they transferred Kutinchev's I. Army from the old Serbian frontier (Vidin–Pirot front) to Ivanov's theatre, placing the newcomers on the outer flank of the advancing Greeks. On July 25 Ivanov and Kutinchev simultaneously attacked the leading troops of the Greek central or Struma column[1] before the main body was clear of the Kresna defile. But the capacity of resistance of the Greek troops, especially in mountain country for which their aptitude was remarkable throughout these campaigns, enabled them to weather the first crisis; they were reinforced from the left as well as from the rear, and on the night of the 26th–27th the Bulgarians withdrew towards the Jumaya Pass.

The venture was at an end. Surrounded by hostile columns converging on Sofia from every quarter, Bulgaria yielded on July 31, and on Aug. 10 was signed the Peace of Bucharest.

Bibliography.—The outbreak of the World War in 1914 prevented all the combatants of the Balkan wars from producing official histories, and the only sources available are books and papers published immediately after the operations. Concise military accounts of the first war in all theatres are Boucabeille's *Guerre Turco balkanique* and Immanuel's *Balkankrieg*. For the Macedonian campaign and Scutari, by far the best authority is the French general staff publication *Revue mil. des armées étrangères* (monthly numbers Feb.–July 1914). For the campaign of 1912 in Thrace, A. de Pennenrun's *Campagne de Thrace* is the best contemporary account; an interesting study by Maj. (afterwards Brig.-Gen.) P. Howell, *The Campaign in Thrace* (1913), stops short before Chatalja. In 1915 Gen. Palat produced a volume, *Guerre des Balkans*, which assembles most of the known evidence for the Thracian campaign. For the second war of 1913 very little of military value has been published. A summary of dispositions, movements, and events will be found in *Hazell's Annual*, 1914, pp. 369–71. For the Serbian part in both wars A. Kutschbach's *Die Serben im Balkankrieg* is useful as containing official information. (C. F. A.)

BALL, SIR ROBERT STAWELL (1840–1913), Irish astronomer, was born in Dublin July 1 1840. Educated at Trinity College, Dublin, he was appointed in 1865 assistant to the Earl of Rosse's observatory at Parsonstown, and whilst there he discovered four spiral nebulae. On the death of Lord Rosse two years later he became professor of mathematics in Dublin University and in 1874 Royal Astronomer of Ireland. This post he held until 1898; but in 1892 he was also made professor of astronomy and geometry at Cambridge and director of the university observatory. From 1897–9 he was president of the Royal Astronomical Society. He was knighted in 1886. He was an admirable lecturer and writer of popular books on his subject, as well as of more learned works such as his *Treatise on Spherical Astronomy* (1885) and *Treatise on the Theory of Screws* (1900); and he was a congenial figure in all circles. He died at Cambridge Nov. 25 1913.

[1] The right, moving more or less independently, was at Dobrinishte in the Mesta valley. The left had reached Pehchevo.

BALL, THOMAS (1819–1911), American sculptor (*see* 3.263), died at Montclair, N. J., Dec. 11 1911.

BALLIN, ALBERT (1857–1918), German merchant and one of the most eminent representatives of German commercial interests, was born Aug. 15 1857 at Hamburg. After having completed his mercantile training he organized the 'tween-deck (emigrant) traffic of the Carr Line. He next undertook the management of the passenger traffic of the Hamburg-Amerika Line and became in 1886 director and soon afterwards director-general of that enterprise, the expansion of which was essentially his work. The share capital of the Hamburg-Amerika Line was increased tenfold during his management. The network of its service was extended over the whole world, largely by the acquisition of a number of other lines. Ballin succeeded, by means of agreements with other German shipping companies, in developing German shipping on a grand scale; he was likewise the author of the German-American shipping agreement of 1902. He was regarded as enjoying the special confidence of the Emperor William II., who employed his services as an expert in all matters of shipping and commerce. Ballin died suddenly—heart-broken, it is said, by the military, political and commercial collapse of Germany—at Hamburg on Nov. 9 1918. (C. K.)

BALLISTICS (*see* 3.276*).—I. INTERIOR BALLISTICS. Interior Ballistics has as its province the behaviour of a projectile, its propellant, and the gun from which it is being fired between the moment of firing and the moment at which the shell leaves the muzzle of the gun. From its nature it is a subject in which the synthesis of experimental results into general laws is a matter of great difficulty, and, in its present stage of development, striking differences of opinion still exist on fundamental points. A review of the work published after 1910 illustrates some of these differences.

In France the well-known system of Gen. P. Charbonnier, published in 1908, has been modified as well as elaborated by G. Sugot (*Mémorial de l'Artillerie navale*, 1913). Charbonnier, for French nitro-cellulose powder in long flat strips, assumes a rate of burning directly proportional to the pressure, and that the grains burn with a distinctly decreasing surface, while Gen. Gossot and R. Liouville (the exponents of the other leading French system) assume, for the same propellant, a rate of burning proportional to the pressure to the power of two-thirds, and a practically constant burning surface.

In Italy Madaschi's revision (published in 1914) of Bianchi's *Nozioni Fondimentali di Balistica Interna* sets forth a very comprehensive system on different lines to that of Charbonnier, although it has some points in common such as the law of burning and the treatment of the resistance of the driving band.

In the U.S. official *Text Book of Ordnance and Gunnery* (1917) Ingalls' system of Interior Ballistics has been replaced by that of Tschappat, who again has adopted the same law of burning and treatment of band resistance as Charbonnier, but then diverges entirely from his methods.

Published in England we may note Sir George Hadcock's "Internal Ballistics" (*Proc. Royal Society*, A, vol. 94, London 1918), in which the treatment of the resistance of the band is extended to include a separate phase while the band is actually being engraved.

The existence of such important divergencies between published systems would in any event make it difficult to present the subject in brief and definite form. But there is also a further obstacle in the fact that the connexion between Interior Ballistics and the design of artillery *matériel* is so intimate that much of the resulting work is still considered by the naval and military authorities of most countries, if not of all, as to a great extent confidential.

On the other hand the experiences of the World War emphasized the importance of a due appreciation of the general principles of Interior Ballistics not only for purposes of design, but also for the intelligent and efficient employment of artillery *matériel*. To establish such an appreciation on a concrete basis, working formulae are a necessity, as without them the magnitude of the effects cannot be studied, but the formulae should be comparatively simple, or from their cumbersome nature they will fail in their object. Formulae suitable for this purpose, although of a purely empirical nature, are available, and it is feasible to present and illustrate the leading principles with the aid of these simple formulae alone.

Monomial Formulae for Velocity and Pressure.—Interior Ballistics is concerned with the circumstances attending the motion of the shell in the bore of the gun. Considering these circumstances in a general way, when the charge is ignited, gas is evolved from the burning surface, and this gas exerts a gradually increasing pressure on the base of the shell. When a certain pressure has been developed the shell starts to move and travels up the bore with continually increasing velocity until it leaves the muzzle of the gun with a certain *muzzle velocity*. During this travel up the bore the pressure at first increases comparatively rapidly until a certain pressure, the *maximum pressure*, is reached. The pressure then gradually decreases to the muzzle, the pressure when the shell leaves the muzzle being known as the *muzzle pressure*.

Modern propellants are for the most part colloids, and the grains composing the charge have some more or less definite geometrical shape. Typical velocity and pressure curves for such propellants will be found in the earlier article BALLISTICS (*see* 3.276–7). A charge made up in this way is in practice ignited in the chamber of the gun by means of a small additional charge of black powder, the *igniter* (which in turn has been ignited by the cap, primer, or tube), so that the whole of the surfaces of the grains are set alight or *inflamed* as nearly as possible simultaneously. For such colloid propellants the "Law of Burning by Parallel Layers" is well established. This law states that at any instant during the burning of the grain the thickness burnt through in the direction normal to the exposed surface is the same over the whole surface, or in other words, that the grain is diminished by an equal thickness in all directions.

The rate of burning of the propellant is a function of the pressure, and the greater the pressure, the quicker the grain will burn.

Consider now two charges of the same weight made up of (*a*) comparatively small and (*b*) comparatively large grains of the same geometrical shape.

For (*a*) the surface exposed when the charge is ignited (the "initial surface") will be greater than for (*b*), and the emission of gas will be greater to start with. The pressure and the rate of burning will increase comparatively rapidly, and the whole charge will be consumed sooner than in the case (*b*). In the case of (*b*) the total weight of gas emitted will be the same, but the mode of emission will be different. The initial surface is not so great, so that at the start the pressure will rise less rapidly and the combustion will be completed later. The maximum pressure will occur later and will be less than for (*a*), but will decrease more slowly.

Coming to the geometrical shape of the grain, the different forms employed may be divided into three main groups:

(i.) Those which burn with a continually decreasing surface. To this group belong all solid grains and short cylinders with an axial perforation.

(ii.) Those which burn with a practically constant surface, such as long thin tubes.

(iii.) Those which burn with an increasing surface to a certain stage, the grain then breaking up into other forms quite different from the original shape. An example of this type is a cylindrical grain pierced longitudinally by a number of holes.

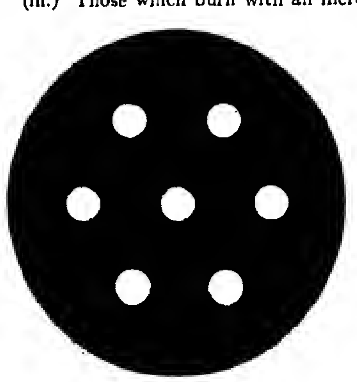


FIG. 1.

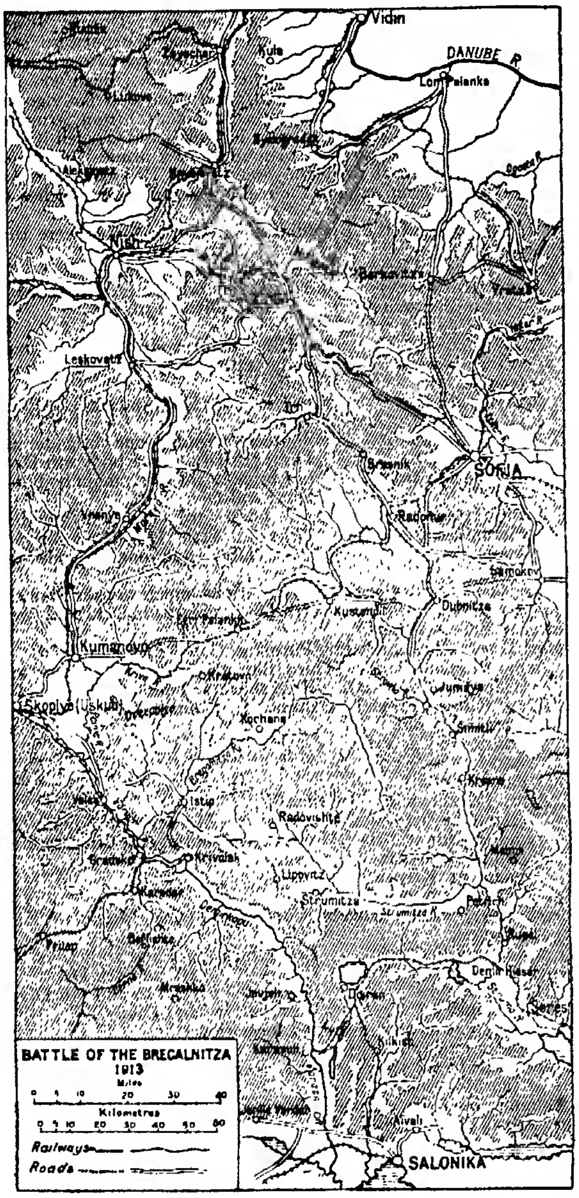
Cordite M.D.T. is an example of Group (ii.). The length of the tubes of circular section of which the charge is composed is so great compared with their thickness, that the burning of the ends may be neglected, and the surface of combustion is practically constant throughout the burning, as the tubes burn both inside and out. The proportion of the whole thickness burnt through at any time is the same as the proportion of the weight or volume of the whole tube consumed.

Cordite M.D., which is made up in long cords of circular section, is an example of Group (i.), and other forms frequently employed are long flat strips of rectangular section (such as the French B.N. powders), or square flat grains (such as ballistite). In all these forms the percentage of the thickness burnt through at any time of the burning is less than the percentage of the whole weight of the grain consumed.

* *These figures indicate the volume and page number of the previous article.*

time the Bulgarian forces between Shtip and Krivolak were slowly driving back Timok II. to the Bregalnitsa, but it was now too late for this to influence either the main battle or that of the Greek front.

On the latter, the Bulgarian advance had come to a standstill, as soon as King Constantine had brought up his reserves, and the



counter-offensive opened on the 3rd. His left (10th and 3rd Divs.) retook Gevgeli, his centre (4th, 2nd, 5th) Kilkish, and his right (1st, 6th, 7th) drove back the Bulgarian left on Nigrita and also eastward on the Seres road (July 3-4). On July 7 the Greek right reached the Salonika-Drama railway, and their left from Gevgeli carried the pass over the Belashitsa which leads to Strumitsa. Thus Ivanov was cut off from the railway, and his only line of retreat lay up the narrow Struma valley to Jumaya.

Yielding to necessity, the Bulgarian forces on the Vardar withdrew, ere it was too late, into the Belashitsa valley, while those pursuing Timok II. on the lower Bregalnitsa halted and drew back.

The opportunity which thus presented itself to the Serbian III. Army of interposing between Ivanov and Bulgaria led to a regrouping of the Serbian forces for the benefit of this army, which, pursuing its advantage, drove back its opponents towards the line of mountains in the upper Bregalnitsa bend (Obozna-1340-Grlena).

But the Bulgarians, in order to relieve pressure and to keep their hold upon Western opinion, seized the initiative again while the regrouping was in process and the Greeks had hardly yet entered the Struma and Strumitsa valleys.

Their new offensive was twofold—local attacks by the I. and V. Armies on all the routes leading into Old Serbia, and heavy counter-attacks on the front of the Serbian I. Army. The first, made with columns of varying strengths on the routes leading to Zajechar, Kynashevats, Pirot and Vlasina, was repulsed by the Serbian II. Army after some initial successes, and was over by July 10. The second was more serious, and it seems that the process of building up the strength of the Serbian III. Army opposite Kochana was not only suspended but actually reversed to cope with a crisis. Finally, however, the Bulgarians were repulsed here also, and retired to the line of frontier mountains (Golemi Vrh-Bozderitsa-Rujan-Sivakobila), more or less in touch with the right of the forces in the mountains of the Bregalnitsa bend.

By this time the Greeks were in possession of the Strumitsa basin and had made some progress up the Struma. But Ivanov had obtained an opportunity that he could not have gained by his own efforts to extricate the various forces of the Bulgarian left which were scattered from the Vardar to the Struma.

The new allied offensive, therefore, begun all along the Serbian line on the 15th, and starting on the battle-front above mentioned (Golemi Vrh-Sivakobila-Obochna), resolved itself into a series of local combats with the object of cutting off as much as possible of Ivanov's rearguard detachments and of making strategic connexion with the Greek left at Pehchevo. At this stage, indeed, bolder strategy was hardly required, for already Rumania had declared war on Bulgaria and had begun an unopposed march on Sofia, while the Turks at Chatalja and Bolair, ignoring the Treaty of London, reoccupied Adrianople without firing a shot.

Yet this relative inactivity of the Serbs gave the Bulgarians one more opportunity, which they seized. Using a manoeuvre which was destined to become a familiar practice of strategy in the World War, but, at that date and in that country of mountains and primitive communications, was conspicuously daring and novel, they transferred Kutinchev's I. Army from the old Serbian frontier (Vidin-Pirot front) to Ivanov's theatre, placing the newcomers on the outer flank of the advancing Greeks. On July 25 Ivanov and Kutinchev simultaneously attacked the leading troops of the Greek central or Struma column[1] before the main body was clear of the Kresna defile. But the capacity of resistance of the Greek troops, especially in mountain country for which their aptitude was remarkable throughout these campaigns, enabled them to weather the first crisis; they were reinforced from the left as well as from the rear, and on the night of the 26th-27th the Bulgarians withdrew towards the Jumaya Pass.

The venture was at an end. Surrounded by hostile columns converging on Sofia from every quarter, Bulgaria yielded on July 31, and on Aug. 10 was signed the Peace of Bucharest.

He died at Cambridge Nov. 25 1913.

[1] The right, moving more or less independently, was at Dobrinishte in the Mesta valley. The left had reached Pehchevo.

by supposing the gun under consideration, together with its shell and charge, to be expanded or contracted symmetrically until its calibre is equal to 1 inch. Corresponding to G, W, S, M, and L, for the gun calibre d in. we shall have for the standard gun

$$G_1 = \frac{G}{d^3},\ S_1 = \frac{S}{d},\ M_1 = \frac{M}{d^3},\ W_1 = \frac{W}{d^3},\ L_1 = \frac{L}{d}$$

V and P will remain unchanged.

The working formulae for muzzle velocity and maximum pressure will be based on the assumption that they can be put in the form—

$$(1) \qquad V = K_v G_1{}^g S_1{}^s W_1{}^w M_1{}^m L_1{}^l$$

$$(2) \qquad P = K_p G_1{}^g W_1{}^w M_1{}^m L_1{}^l$$

Where g, s, w, m, and l are empirical indices, positive or negative integral or fractional, and K_v, K_p empirical constants. The values of the indices denoted by the same letter are different in (1) and (2).

These formulae are to be regarded as purely empirical, but with a due appreciation of their possibilities and limitations they will be found very useful working tools.

Assuming as the result of experience, suitable values for the indices, we can from known firing results (muzzle velocity and maximum pressure) for a certain gun, charge, and shell evaluate K_v and K_p of (1) and (2) by simple calculation with a table of logarithms. Then by a reverse process, using the values of K_v and K_p so obtained, we can calculate the muzzle velocity and maximum pressure to be expected with another gun, shell, and charge (of the same propellant made up of grains of the same form), inserting the appropriate values of G_1, S_1, W_1, M_1 and L_1 in (1) and (2).

The following tables have been drawn up as a guide to values of the indices which will be found suitable for guns, at any rate for trial purposes, with the following propellants:—

Long cords of Cordite M.D. (M.D.).
Long tubes of Cordite M.D.T. (M.D.T.).
Short tubes or m.p. grains of nitrocellulose (N.C.T.).

g.	*w*.	*m*.	*l*.
M.D.T. −1·00		M.D.T. −1·8	M.D.T., N.C.T. −1·40
N.C.T. −1·10	+0·6	N.C.T., M.D. +1·6	M.D. −0·85
M.D. −1·15			

An example to illustrate the uses of these tables will now be given:—

A 6-in. gun, chamber capacity 1600 in., shot travel 250 in., fires a 100-lb. shell with a charge of 25 lb. of M.D., diam. of cord 0·2 in., gives a muzzle velocity of 2650 f/s with maximum pressure of 16 ton/in². What muzzle velocity and maximum pressure may be expected from a 5-in. gun, chamber capacity 600 in., shot travel 140 in. with a 55-lb. proj. shell and a charge of 10 lb. M.D., diam. of cord 0·12 inches?

For the 6-in. gun we have:—

$G = 1600$	$G_1 = 74$
$S = 250$	$S_1 = 41{\cdot}6$
$W = 100$	$W_1 = 0{\cdot}463$
$M = 25$	$M_1 = 0{\cdot}156$
$L = 0{\cdot}2$	$L_1 = 0{\cdot}033.$
$V = 2650$	
$P = 16$	

From (1) and Table I.—

$$V = K_v\, G_1{}^{-0\cdot25}\ S_1{}^{0\cdot2}\ W_1{}^{-0\cdot4}\ M_1{}^{0\cdot6}\ L_1{}^{-0\cdot15}.$$

Taking logarithms and rearranging,

$$\log. K_v = \log. V + 0{\cdot}25 \log. G_1 + 0{\cdot}6 \log. 1/M_1 - 0{\cdot}2 \log. S_1 - 0{\cdot}4 \log. 1/W_1 - 0{\cdot}15 \log. 1/L_1$$

whence

$$\log. K_v = 3{\cdot}524.$$

Similarly from (2) and Table II.—

$$P = K_p\, G_1{}^{-1\cdot15}\ W_1{}^{0\cdot6}\ M_1{}^{1\cdot6}\ L_1{}^{-0\cdot85}$$

whence

$$\log. K_p = 2{\cdot}645.$$

Then for the 5-in. gun:—

$G = 600$	$G_1 = 4{\cdot}8$
$S = 140$	$S_1 = 28$
$W = 55$	$W_1 = 0{\cdot}44$
$M = 10$	$M_1 = 0{\cdot}08$
$L = 0{\cdot}12$	$L_1 = 0{\cdot}024.$

and

$$\log. V = \log. K_v + 0{\cdot}2 \log. S_1 + 0{\cdot}4 \log. S_1 + 0{\cdot}15 \log. 1/L_1 - 0{\cdot}25 \log. G_1 - 0{\cdot}6 \log. 1/M_1$$

which, using the value of log. K_v found for the 6-in. gun, gives

$$V = 2350 \text{ f/s.}$$

Similarly using the value of log. K_p found for the 6-in. gun we get for the 5-in. gun

$$P = 18{\cdot}6 \text{ ton/in}^2.$$

It must not be inferred from this that for any propellant we can arrive at values of K_v and K_p and the indices g, s, w, m, l, which will reproduce the firing results in all circumstances. Investigations to determine such fixed values once for all, will soon lead to disappointment. It must be remembered that we have only embodied in the formulae differences in weight, calibre, chamber capacity, shot travel, weight of shell, weight of charge, and dimensions of the propellant. We have not taken into account any of the other causes of variation touched on above.

When we analyze firing results by means of (1) and (2) all these neglected factors are as it were embodied in the values of K_v and K_p arrived at, and these values of K_v and K_p and also the values of the indices are only suitable for application in other cases in which the effects of the neglected factors are proportionally similar.

The "density of loading,"[1] and the position of the point of complete combustion of the charge will also have an influence, and an adjustment of constants and indices may be necessary for widely different densities of loading, and according as to whether the charge is completely consumed well back in the gun, or whether there is a proportion of the charge still unburnt when the shell leaves the muzzle.

The values of the indices in Tables I. and II. are adjusted for the average conditions of modern practice,[2] and if the above warning is kept in mind and the formulae used in an intelligent manner they will, as already stated, be found extremely useful working tools.

If only a few of the data vary it is not necessary to work with the complete formulae (1) and (2). Thus if we are dealing with the same gun and shell and the same propellant of the same form and size, and only wish to investigate the effect on the muzzle velocity of differences in weight of the charge, we need not introduce the standard gun and work out the constant K_v but may write

$$\frac{V'}{V''} = \left(\frac{M'}{M''}\right)^m$$

where the muzzle velocity V' is known for a charge of weight M', and we want to find the velocity V'' for a charge M''. Again if we are dealing with differences in weight of both charge and shell we may employ

$$\frac{V'}{V''} = \left(\frac{M'}{M''}\right)^m \quad \left(\frac{W'}{W''}\right)^w.$$

As an example—a gun gives m.v. 2500 f/s with full charge 12 lb. M.D.T., what will the m.v. be with a 3/4 charge of 9 lb.?

Here $V' = 2500$ for $M' = 12$, and we have to find V'' for $M'' = 9$ from

$$\frac{V'}{V''} = \left(\frac{M'}{M''}\right)^{0\cdot7}$$

we have

$$\frac{V'}{V''} = \left(\frac{12}{9}\right)^{0\cdot7} = (1{\cdot}33)^{0\cdot7} = 1{\cdot}22.$$

Therefore $\qquad V'' = \dfrac{2500}{1{\cdot}22} = 2050$ f/s.

When the variations in the data are comparatively small the monomial formulae may be replaced by a simple percentage approximation which will give sufficient accuracy while reducing the calculations to little more than easy mental arithmetic. The following tables derived from the indices already employed with the monomial formulae give the information necessary for such percentage calculations.

---

[1] The density of loading is defined as the "ratio of the weight of the charge to the weight of a volume of water just sufficient to fill the chamber." This is given by 27·7 M/G. The greater the density of loading, the less the "initial air space" (the volume of the chamber not actually occupied by the grains of the charge).

[2] These indices are suitable for ordnance. For rifles they require considerable modification, see Hardcastle "Monomial Formulas for Pressure and Velocity for Ordnance and Small Arms," *Royal Artillery Journal*, vol. xlii.

TABLE III.

Percentage alteration in muzzle velocity due to an alteration of +10% in—

Chamber Capacity.	Shot Travel.	Weight of Shell.	Weight of Charge.	Least Dimension of Grain.
−2·5%	+2%	−4%	M.D.T. +7% N.C.T. +6% M.D. +6%	M.D.T. −3% N.C.T. −3% M.D. −1·5%

TABLE IV.

Percentage alteration in maximum pressure due to an alteration of +10% in—

Chamber Capacity.	Weight of Shell.	Weight of Charge.	Least Dimension of Grain.
M.D.T. −10% N.C.T. −11% M.D. −11·5%	+6%	M.D.T. +18% N.C.T. +16% M.D. +16%	M.D.T. −14% N.C.T. −14% M.D. −8·5%

Example. A gun gives m.v. 1680 f/s for max. press. 15·5 ton/in² with a charge of 20 lb. N.C.T. What decrease in charge will give a velocity of 1660 f/s, and what will be the corresponding pressure?

A change from 1680 to 1660 f/s is a decrease of 1·19%. From Table III. a decrease of 10% in weight of charge will decrease m.v. 6%. Therefore a decrease of 1·19% will correspond to a decrease

in weight of charge of $\frac{10\times 1\cdot 19}{6} = 1\cdot 98\%$ or 0·396 lb.

From Table IV. 10% decrease in charge decreases P by 16%. Therefore 1·98% decrease in charge decreases P by 3·16% = 0·49 ton/in.² Hence the maximum pressure for V = 1660 f/s will be about 15 ton/in.²

For the experimental determination of any of the indices, say the velocity index *m*, we require a series of firing results in which the corresponding quantity M has alone been varied, and the muzzle velocities recorded.

The logarithms of the corresponding values of V and M are then plotted as ordinates and abscissae and a straight line fitted to the points as closely as possible. The slope of this line, as measured by the tangent of the angle which it makes with the axis of M, gives the value of the index.

As an example fig. 3 shows the plotting by this method of a number of firing results for a certain gun with different weights of charge, all the other particulars being kept the same.

The firing results plotted were:

M lb.	6·12	6·62	7·69	8·0	9·0	10·25	11·0
V f/s	816	865	959	991	1071	1164	1222

The points obtained are shown by small circles.

It is then evident that a straight line as shown on the diagram can be drawn which will pass very nearly through all the points.

The best straight line could be determined mathematically by the "method of least squares," but in practice all that is necessary is to take a piece of thin black thread and move it about on the diagram estimating the best position by eye. Drawing the best straight line determined in this simple manner we can read off the index *m*. In the present case we thus arrive at the result that $m = 0\cdot 7$, so that

$$\frac{V'}{V''} = \left(\frac{M'}{M''}\right)^{0\cdot 7}$$

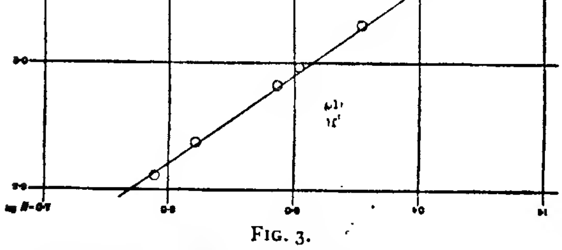

FIG. 3.

Connexion between Interior and Exterior Ballistics.—When the shell leaves the muzzle of the gun and starts to describe its trajectory it enters the domain of Exterior Ballistics, but the condition in which it leaves the muzzle, particularly as regards initial velocity and steadiness and the round-to-round variations in these conditions, will have an important influence on the behaviour of the individual rounds, and on the dispersion of a group of rounds fired from the same gun at the same elevation. These initial conditions are determined by what happens as the shell travels up the bore and at the moment it leaves it, and it is therefore appropriate to touch on them here.

Thus, if the shell leaves with a large initial "yaw" (inclination of the longer axis to the direction of motion of the centre of gravity), the range will in general be less than that which would be obtained if the initial yaw were small. Again, from the point of view of dispersion, even although all the shell were equally steady, the greater the round-to-round variation in the muzzle velocity, the greater would be the dispersion in range.

From the point of view of accuracy, as measured by the small dispersion of a group of rounds fired at the same elevation, the round-to-round variation in the initial conditions should be as small as possible. As far as regularity in muzzle velocity is concerned, the charge is a main factor, but the driving band and the state of the bore also have an effect.

Considering the charge, the constituents of this should be, in the first place, as homogeneous as possible, both as regards composition and dimensions. Further, for the same shape of grain the longer the travel of the shell before the charge is completely consumed, the more sensitive is the muzzle velocity to variations in size, etc., so that the further back the charge can be burnt the better, or the smaller the size that can be used the better. This is of course limited by the muzzle velocity required; the smaller the size the less muzzle velocity can be obtained for the same maximum pressure.

When we come to consider the degree of steadiness with which the shell leaves the muzzle and the variations in this, while there is no question as to its importance, the conditions which govern it and their relative importance are by no means well established.

The shell has to be given rotation, by means of the rifling grooves, in order to maintain an end-on position in its subsequent flight, and, in the first place, it is clear that it must be satisfactorily centred when rammed home, and that the design of the rifling grooves and driving band must be mechanically suitable for imparting the rotation in an efficient manner. Further we have as possible influences on the conditions of emergence, the effect of the blast of the gases as they are released at the muzzle, and the effect on the shell of the vibrations of the barrel. As to the former the violence of the blast effect will depend on the muzzle pressure, and the general practice is to keep this as low as possible so as to decrease the chances of trouble from this cause. As to barrel vibrations, although some experimental work has been done in the case of rifles, there is very little really known as to the behaviour of ordnance in this respect, and their influence on the state of departure of the shell. It is a matter which undoubtedly calls for research, but the experimental and theoretical investigation bristles with formidable difficulties.

Bibliography.—A list of some recent works and papers on the subject is appended. It is not intended to be complete but covers a good deal of ground, and may be useful in suggesting a course of reading which might be undertaken by anyone intending to study the subject seriously. Liouville, *Les Effets des Explosifs* (1919); A. G. Hadcock, "Internal Ballistics," *Proceedings of the Royal Society*, A, vol. 94, London, 1918; G. Sugot, "Les Formules de Charbonnier," *Memorial de l'Artillerie Navale* (1913); W. H. Tschappat, *Text Book of Ordnance and Gunnery* (1917).

(R. K. H.)

II. EXTERIOR BALLISTICS. Previously to the World War, and under the practice in vogue in 1910, guns proper were used only in direct fire at elevations below 20 degrees. Fire from guns, howitzers or mortars, above 15° elevation was known as high angle fire, and fire from howitzers at angles of elevation below 15° was known as curved fire. Howitzers were fired at elevations up to 45°; mortars were used at angles of elevation up to 65°; but howitzers and mortars had low muzzle velocities, relatively short ranges, and the maximum ordinates of their trajectories were comparatively small.

From 1915, however, the nature of the fighting on the western front called for the development of extreme ranges in all artillery, and the easiest and quickest method of increasing the range of a given gun was to modify or redesign its mount so as to permit the piece to be fired at the angle of elevation that would produce the maximum, or at any rate the necessary, range. The method was adopted by all the armies for all calibres of land guns. Furthermore, anti-aircraft guns were designed to permit of all angles of elevation up to 90 degrees. Thus for the first time it became necessary to have a knowledge of all the elements along the trajectory and not merely of the range, time of flight, etc., of the horizontal trajectory. Soon after the war started, improvements in projectiles, which had been developing slowly since 1900, began to make themselves felt in still further increasing ranges.

Causes which led to New Methods.—Siacci's method involves an assumption (*see* 3.274, Equation 59), which introduces an error, if an attempt is made to complete the whole trajectory in a single arc, when the angle of departure is more than 20 degrees. The method of "successive arcs," based on Siacci (*see* 3.275), has been used extensively and has the required accuracy, providing the arcs taken are short, but the method is laborious and has other disadvantages arising from the discontinuity of the successive arcs. To overcome these difficulties and at the same time simplify calculations on trajectories, England and France and later the United States adopted the method of numerical integration of the differential equations of motion of the projectile as the standard method of solution. In all these countries the best mathematical talent was brought to bear on the solution of this problem, which in peace-time had received the attention only of a limited number of officers and others connected with the military and naval services and of a few civilians.

The outline of the method of numerical integration given below is that first proposed by F. R. Moulton in the United States, and developed to a high degree by the mathematicians and others associated with him in the study of ballistic problems during the World War. Other methods worked out in England and France, while possessing the same advantages over the older methods, are perhaps not so simple in their application.

Preliminary Assumptions.—For purposes of small arc computations, the retardation of the projectile with normal air density at the gun is represented by

$$(1) \qquad R = \frac{vG(v)Hy}{C}$$

where R is the retardation of the projectile,
- v, the velocity in metres of the projectile in the direction of its motion.
- $vG(v)$, a function of v, experimentally determined; the retardation due to air resistance of a projectile of ballistic coefficient = 1, moving horizontally at the height of the muzzle of the gun in air at a temperature of 15° C. and a pressure of 760 mm., 78% saturated with water.
- $H(y)$, a function of the altitude y (above the muzzle of the gun); the ratio between the density of the air at that altitude and its density at a zero altitude.
- C, the ballistic coefficient.

Law of Air Resistance.—The results obtained from any mathematical analysis of the motion of a projectile depend for their accuracy upon the care with which the law of air resistance has been experimentally determined. (For a description of the method and calculations by which Bashforth's ballistic tables, including the law of air resistance, were determined, *see* 3.271, 272.) In later experiments the same essential methods were followed with the use of more accurate instruments and with projectiles more nearly of the modern form. Such are the Krupp experiments (*see* 3.273), and the Gavre Commission experiments made in 1888. Chief Engineer Garnier has smoothed out the irregularities in the results of the Gavre Commission firings and has thus obtained a law of air resistance which, while not differing essentially in any region from the results of experiments, is of a continuous character. This cannot be said of Zabudski's law based upon various powers of the velocity.

The G Function.—The retardation of the standard projectile due to standard air resistance is put in the form $v\,G(v)$ for convenience in numerical integration. The function $G(v)$ here represents the ratio between the retardation and the velocity at each instant. $G(v)$ as smoothed out by Chief Engineer Garnier is tabulated with $\frac{v^2}{100}$ as an argument, velocities and retardations being expressed in his tabulated form in metres.

On the next page (p. 388), Table I. gives an abridged table of the G Function (G is the retardation divided by the velocity, for C = 1 and at surface air density), based on the French tables, giving 10 log G with the argument $\frac{v^2}{100}$; v expressed in metres per second.

The B Function.—The retardation function is sometimes written $v^2B(v)$, and then $B(v)$ is the ratio between the retardation and the square of the velocity. In those regions and under those conditions where the "square law" of resistance holds true, $B(v)$ is a constant. Figure 1 shows Mayevski's and Zabudski's values for $B(v)$ or $\frac{G(v)}{v}$ as compared with Garnier's smoothed-out Gavre Commission values. The tremendous change in the law in the neighbourhood of the velocity of sound is to be noted. More recent but uncompleted

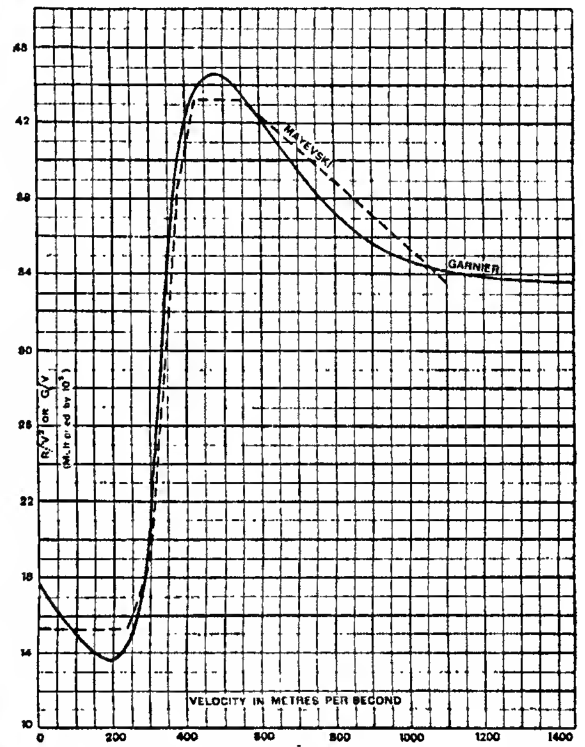

FIG. 1.

experiments indicate that the disturbance in the vicinity of the velocity of sound may be changed in amount and displaced in position by changes in the form of the projectile.

Density Function.—The air density function $H(y)$ is intended to represent the normal change in density of the air with height. The value of the density function here assumed is,

$$(2) \qquad H(y) = 10^{-.000045y}$$

where y is in metres. The coefficient of y is subject to seasonal variations. (*See Cours de Ballistique*—G. Sugot, 1918.)

The density function merely expresses the law of change of density with altitude. It is quite possible to calculate trajectories in air that do not follow this or any other continuous law, providing we know the density at each height. It is necessary, however, in the calculation of ballistic tables to follow some definite law in order to make the tables consistent throughout. Seasonal variations and other variations from the assumed law are taken care of in differential corrections as will be explained below.

The Ballistic Coefficient.—The ballistic coefficient is represented by the formula,

$$(3) \qquad C = \frac{w}{i\,d^2} \text{ where}$$

w is the weight of the projectile in pounds.
d, the diameter of the projectile in inches.
i, a factor called the coefficient of form which accounts for differ-

ences in air resistance between projectiles now used and those with which the air resistance law was determined. Its value, 1 for the projectiles of the form used in determining the air-resistance law, is as low as 0·47 for modern sharp-pointed, boat-tailed projectiles. Its value can be accurately determined for any projectile by working backward from the results of firing. Such determinations show that the value may and usually does vary for the same projectile if fired at different ranges.

The Differential Equations of Motion of the Projectile.—Neglecting the convergence of the action lines of gravity due to the spheroidal form of the earth and also the slight diminution in the intensity of the force of gravity due to the height which modern projectiles reach, we may write the differential equations of motion of the projectile considered as a material point, as follows:—

$$(4)\qquad \frac{dx'}{dt} = -\mathrm{R}\cos\theta = x''$$

$$(5)\qquad \frac{dy'}{dt} = -\mathrm{R}\sin\theta - g = y''$$

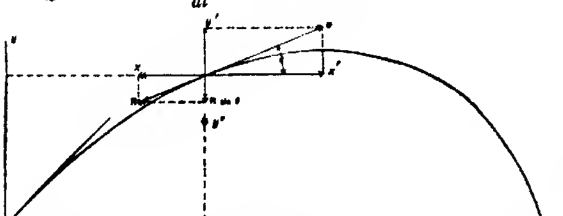

FIG. 2.

where, (*see* fig. 2), x is the abscissa of any point of the trajectory, positive to the right,

x', the horizontal component of the velocity at that point,
x'', the horizontal component of the acceleration,
y, the ordinate corresponding to x, positive up,
y', the vertical component of the velocity at that point,
y'', the vertical component of the acceleration,
θ, the angle that the tangent to the trajectory makes with the horizontal.

Since v is the velocity of the projectile in the direction of its motion,

$$(6)\qquad \mathrm{Cos}\,\theta = \frac{x'}{v},$$

$$(7)\qquad \mathrm{Sin}\,\theta = \frac{y'}{v}$$

and if we assume

$$(8)\qquad \mathrm{E} = \frac{\mathrm{R}}{v}$$ as the ratio between retardation and velocity, we may write (4) and (5) as follows:

$$(9)\qquad x'' = -\mathrm{E}\,x'$$

$$(10)\qquad y'' = -\mathrm{E}\,y' - g.$$

In this form the equations are used in the construction of trajectories by the method of numerical integration.

By reference to (1) we see that,

$$(11)\qquad \mathrm{E} = \frac{\mathrm{G}(v)\,\mathrm{H}(y)}{\mathrm{C}}.$$

In this equation, G is a function of the velocity alone, as given in Table I. H is a function of the altitude alone as given by equation (2). C is a function of the weight and form of the projectile as given in equation (3). As in the older ballistic methods, C implicitly includes unknown variations from standard conditions in such quantities as density of the air, moisture in the air, temperature of the air, yaw of the projectile, *i.e.* angle between the longer axis of the projectile and the tangent to the trajectory.

However, for the purpose of the construction of ballistic tables, as distinguished from range tables, atmospheric conditions are assumed normal and trajectories are constructed with known values of C. In the construction of range tables by the use of ballistic tables or by direct calculation, changes in air density at the gun are accounted for by a factor Δ representing the density placed in the denominator of the expression for C, equation (3), and changes in form of head, yaw, etc., by the factor i, in that expression. As used here the term "yaw" means the divergence of the axis of the projectile from the tangent to the trajectory, both on account of initial instability and of curvature of the trajectory away from the direction of the axis at a later period.

Example of Numerical Integration.—To illustrate the manner in which equations (9) and (10) may be integrated numerically, we shall assume an example as follows:

Example I.—A 155 mm. gun fires a projectile having a ballistic coefficient of 3·6, with an initial velocity of 2,400 ft. per second, at an angle of elevation of 30 degrees. To determine the elements of the trajectory, assuming normal atmospheric conditions:—

The values of G and H are given in metres-per-second velocity and metres height respectively, so that all velocities and distances must be reduced to metres.

Initial Conditions.—At the gun we have

$$v = 2{,}400 \text{ ft. per second} = 731{\cdot}5 \text{ metres per second}$$
$$\theta = \phi = 30^\circ$$
$$x' = 731{\cdot}5 \cos 30^\circ = 633{\cdot}5$$
$$y' = 731{\cdot}5 \sin 30^\circ = 365{\cdot}8$$
$$y = 0.$$

Since $\frac{v^2}{100}$ is 5351, the value of log. $G(v)$ from the G table is 9·4515.

Since y is 0, $H(y) = 1$.

Placing logarithms in brackets, we then have

$$E = \frac{(9{\cdot}4515-10)}{3{\cdot}6}$$

and

$$E\,x' = \frac{(9{\cdot}4515-10)\times 633{\cdot}5}{3{\cdot}6} = 49{\cdot}78 = -x''$$
$$E\,y' = \frac{(9{\cdot}4515-10)\times 365{\cdot}8}{3{\cdot}6} = 28{\cdot}74$$

and

$$E\,y'+g = 28{\cdot}74+9{\cdot}81 = 38{\cdot}55 = -y''.$$

At the start, then, the horizontal velocity of the projectile is decreasing at the rate of 49·78 metres per second and the vertical component of the velocity is decreasing at the rate of 38·55 metres per second.

First Interval—First Approximation.—If we take a small interval of time, we do not make any great error in assuming that the retardations during the interval can be based upon the velocity and altitude at the beginning of the interval. Taking a ¼-second interval, the change in components of velocity is 12·4 and 9·6 metres respectively, making the velocities at the end of the first interval,

$$x' = 633{\cdot}5 - 12{\cdot}4 = 621{\cdot}1$$
$$y' = 365{\cdot}8 - 9{\cdot}6 = 356{\cdot}2.$$

These velocities are lower than those that actually exist at the end of the interval, since the retardations are based on the components of the velocity at the beginning of the interval, and are consequently higher than the true average values during the interval. Using the velocity figures just obtained, we find the following values corresponding to the end of the first interval,

$$\frac{v^2}{100} = \frac{(621{\cdot}1)^2+(356{\cdot}2)^2}{100} = 5126$$
$$y = \frac{365{\cdot}8+356{\cdot}2}{2\times 4} = 90{\cdot}2 \text{ metres}$$

$$G(v) = (9{\cdot}4464-10)$$
$$H(y) = (9{\cdot}9959-10) \qquad \text{(from equation (2).)}$$
$$E\,x' = \frac{(9{\cdot}4464-10)\ (9{\cdot}9959-10)\times 621{\cdot}1}{3{\cdot}6} = 47{\cdot}78$$
$$E\,y' = \frac{(9{\cdot}4464-10)\ (9{\cdot}9959-10)\times 356{\cdot}2}{3{\cdot}6} = 27{\cdot}39$$
$$E\,y'+g = 27{\cdot}39+9{\cdot}81 = 37{\cdot}20.$$

Second Approximation.—The values of the components of retardation at the beginning of the interval are based on the velocity at the beginning of the interval and are, therefore, higher than the average values during the interval. The values just obtained for the components of the retardation at the end of the interval are based on a velocity lower than the true one at the end of the interval and are, therefore, lower than the average retardation during the interval. Means between these two sets of retardation components are nearer the average values during the interval than either set. The retardations for the ¼-second interval based on the mean values are,

$$\frac{49{\cdot}78+47{\cdot}78}{2\times 4} = 12{\cdot}2 = -x''$$
$$\frac{38{\cdot}55+37{\cdot}20}{2\times 4} = 9{\cdot}5 = -y''$$

making the velocities at the end of the first interval,

$$x' = 621{\cdot}3$$
$$y' = 356{\cdot}3, \text{ and the altitude,}$$
$$y = \frac{365{\cdot}8+356{\cdot}3}{2\times 4} = 90{\cdot}3.$$

If we now take these values and recompute $E\,x'$, $E\,y'+g$ we find the values 47·80 and 37·21 respectively. In the average components of retardation during the interval no essential change will be found, showing that by a second approximation we have reached a result sufficiently accurate.

Second Interval.—Beginning with the components of the velocity and the altitude of the projectile at the end of the first interval we may now proceed in like manner to determine the components of the retardation during the second ¼-second interval. However, we may shorten the work as we now know not only the values of the retardation components at the beginning of the second interval but also the amounts by which they have changed in the preceding ¼-second. If the same rate of change continues during the second interval we will have for the end of that interval,

$$E\,x' = 47{\cdot}78-(49{\cdot}78-47{\cdot}80) = 45{\cdot}82 = -x''$$
$$E\,y'-g = 37{\cdot}21-(38{\cdot}55-37{\cdot}21) = 35{\cdot}87 = -y''.$$

The corresponding velocities obtained by using the average retardations during the interval as before are:

$$x' = 609{\cdot}6, \text{ and } y' = 347{\cdot}2.$$

The altitude at the end of the second interval is

$$y = 90{\cdot}3 + \frac{356{\cdot}3+347{\cdot}2}{2\times 4} = 178{\cdot}3.$$

Using the last values and again computing retardation components we have

$$E\,x' = 45{\cdot}94$$
$$E\,y'+g = 35{\cdot}98.$$

Velocities and altitude computed from these do not differ from the values obtained in the first approximation, showing that a second approximation is unnecessary in this case.

Continuation of the Process.—Using exactly the same methods, it is possible to determine numerically, step by step, the values of y, x', y', x'', and y''. We might also determine x at each step, but it is not needed in making the step-by-step calculations and is usually more conveniently determined by a summation of x' after all the other values have been determined.

Length of Interval.—In the above example it was assumed that the change in x, y, x' or y' could be found by using the mean of the values of x', y', x'' or y'' at the beginning and end of the interval. To do this without making too large an error we must use a small interval or take account of second differences. The choice of length of interval will depend upon the ballistic coefficient, muzzle velocity and curvature of the trajectory at the point considered. If these, in combination, or separately, are such as to cause rapid changes in the components of the velocity or acceleration, a relatively short interval should be taken, as ¼-second in the examples above. Otherwise, the interval may be increased to ½-second or longer, and when second differences are used, as will be explained below, to two or more seconds.

High velocities or low ballistic coefficients usually require smaller intervals than low velocities or high ballistic coefficients. It will in general be desirable to take a shorter interval at the very beginning of the trajectory than at a later period. In changing to longer intervals it is most convenient, in the computations, to take twice the interval just used. As the velocities increase in the descending branch of the trajectory it may be desirable in some cases to use shorter intervals again. If so, half the length of interval just used should be assumed.

Second Differences.—The length of interval may be increased and the amount of computation materially reduced if second differences are taken into account in computing all of the functions of t, as y, x', y', x'' and y''.

The following table shows the results of further computations on the example discussed above and gives first and second differences of y' for intervals of one second.

t	y	y'	*1st Diff.*	*2nd Diff.*
0	0	365·8	36·0	
1	347·5	329·8	31·7	4·3
2	661·2	298·1	28·2	3·5
3		269·9		

In determining the value of Δy from the average vertical velocity for the interval between $t=2$ and $t=3$, we obtain, if we neglect second differences,

$$\Delta y_{t=2}^{t=3} = \sum_{t=2}^{t=3} y'\Delta t = (269{\cdot}9+\tfrac{1}{2}\times 28{\cdot}2)\times 1 = 284.$$

The following figure showing y' plotted on an exaggerated scale, as a function of t, illustrates the error obtained if only first differences are used. The area of the figure between $t=2$ and $t=3$ is the value of Δy determined by using first differences only, these two as well as other consecutive points on the y' line being connected by a right line.

It is evident that the area of the figure between any two ordinates is greater than if the known y' points were connected by a smooth continuous curve.

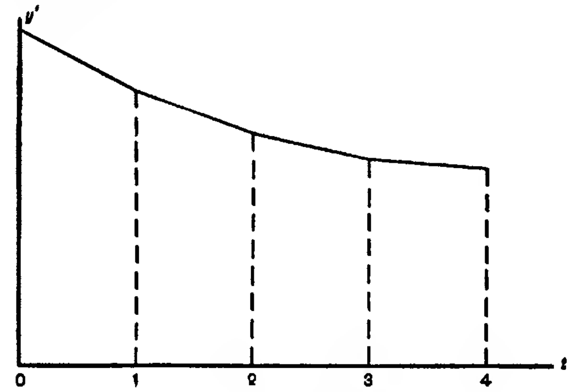

FIG. 3.

It has been shown mathematically that when the points t_0, t_1, t_2, etc., are equally spaced the quantity in brackets in the value of Δy above should be reduced by 1/12 of the second difference, making it,

$$\Delta y_{t=2}^{t=3} = (269{\cdot}9 + 28{\cdot}2 \times \tfrac{1}{2} - 3{\cdot}5 \times 1/12) \times 1 = 283{\cdot}7$$

or more generally, since the same process is used in successively evaluating the other functions x', y', etc., we may write,

$$(12) \qquad \int_{n-1}^{n} f_2(t)dt = \left(z_n + \tfrac{1}{2}a_{n-1} - \tfrac{1}{12}b_n\right)h$$

where $f_2(t_n) = z_n$, $f_2(t_{n-1}) = z_{n-1}$ etc.

n represents the order of the interval, or of the tabulated values of z, a and b.

h, the uniform length of the interval

a, first differences of z

b, second differences of z.

The quantities may be arranged in tabulated form as follows:—

t_1 ....z_1................

................................a_1

t_2.............. .z_2.... ....b_1

....a_2

t_3.. .. ..z_3

The application of the formula will give the successive increments to be applied in evaluating $\int z\, dt$.

The use of second differences in this manner permits the use of longer intervals except at the beginning when no second differences are available. In this case a shorter interval is used and a sufficient number of trials are made or a second difference is estimated by approximate methods.

The integral having been obtained by the methods described, up to any interval, Simpson's rule or other similar method may be used to check the values obtained.

Complete Solution of a Trajectory.—The results of the complete solution of the following example are given in Table II. below:—

Example II.—A 75 mm. gun is fired at an angle of departure of 45°, using a projectile of 15 lb. weight with a form factor, $i = 0{\cdot}6$. The muzzle velocity is 2,175 ft. per second. Determine the coördinates of the trajectory and the horizontal and vertical components of the velocity and acceleration.

TABLE II.

59	13765·72	158·05	3·44	68·14	−253·37	4·28
59.269	13808·10	157·12	3·47	0	−254·49	4·18

It is to be noted that ¼-second intervals are used from 0 to 1 second, half-seconds from 1 to 5 seconds, full seconds from 5 to 30 seconds and two seconds from 30 to 58 seconds. As this was so nearly the end of the trajectory, judging from the value of y, a single second interval was next taken to 59 seconds. The exact values of the other elements corresponding to $y = 0$, or the end of the range, are obtained by interpolation. For this purpose it may be desirable to work out the values for an additional short interval.

For the terminal velocity we have,

$$v = \sqrt{x' + y'}.$$

For the angle of fall,

$$\tan \omega = \frac{dy}{dx} = \frac{dy}{dt} \cdot \frac{dt}{dx} = \frac{y'}{x'}.$$

The results for the end of the range and maximum ordinate are:

Range = 13808·1 m = 15100·7 yd.

Terminal Velocity 299·1 m/s = 327.1 yd/s = 981·3 f/s

$\omega = \tan^{-1} 1{\cdot}61972 = 58°\ 18'\ 55''$

Max. Ord. = 4523·15 m. = 4946·6 yd.

Range to Max. Ord. = 7538·2 m. = 8243·9 yd.

Ballistic Tables.—Using the method of numerical integration described, we may construct a series of trajectories with the values of the muzzle velocity, ballistic coefficient and angle of elevation so chosen and spaced as to cover the field of guns and ammunition in actual use. By proper arrangement of the principal elements of the trajectories thus determined, it is possible to form tables in convenient form for use, from which by interpolation we may obtain the important elements of the trajectories corresponding to any given gun. Such tables have been constructed in France and America.

The American tables, constructed under the supervision of A. A. Bennett, consist of two main tables. The first table is a direct tabulation of the results of numerical integration of trajectories. For this purpose it has been found most convenient and economical of labour to assume a ballistic coefficient and velocity at the summit and construct the trajectory forward and backward from that point. The arguments in this table are the ballistic coefficient, the velocity at the summit and the ordinate from the summit. The table gives the corresponding values of x, x', y' and t from summit forward and backward.

The second table is arranged with C, ϕ and V as arguments and gives X, T, Y and the velocity at the summit.

Assumptions Made in Construction of Ballistic Tables.—In computing trajectories for use in the construction of these tables, the following assumptions were made:—

1. The earth is motionless.
2. There is no wind.

3. The atmospheric density varies with the altitude, according to the H function given by equation (2) and is standard at the muzzle.

4. The action of gravity is uniform in intensity, is directed toward the earth's centre and is independent of the geographical position of the gun. Its value $g=9 \cdot 80$ metres per second.

5. The G function is a function of the velocity alone and has the values given in Table I.

6. The ballistic coefficient C is constant and known.

Differential Variations.—Range tables for artillery must give the data required to lay the gun to strike a target at any desired range, not only for certain conditions fixed as standard for that gun, but also for conditions varying considerably from the standard. The variation may be in the initial conditions as in muzzle velocity, ballistic coefficient, or angle of departure. The initial variations in the ballistic coefficient may be due to variations in the density of the air at the gun, variations in the weight of the projectile or variations in the coefficient of form. Again, the variations may be in subsequent conditions, as in the existence of a range or cross wind, in $H(y)$ or the air density curve for the day, in the rotation and curvature of the earth. The latter is introduced as a variation since it is not considered in the calculation of basic trajectories for the construction of ballistic tables, but its effects are material at long ranges.

Ballistic tables having been constructed we may obtain by mere interpolation the important variations such as that in range caused by variations in the initial conditions. Such variations may then be tabulated in convenient form in the range table.

For variations due to abnormal subsequent conditions, it is necessary to make special calculations, whether these are to be incorporated in the ballistic tables, or merely in the range tables. It would be quite possible to calculate a sufficient number of trajectories under assumed abnormal subsequent conditions to enable one to tabulate in ballistic and range tables the variations due to changes in these conditions, but this procedure would require a tremendous amount of work.

Furthermore, a variation in, say the range, due to variations in conditions is the difference between the range under the normal conditions and the range under the abnormal conditions. If we determine the variations by determining each range separately and taking the difference we are introducing the errors in two large quantities into a small quantity. The percentage error in the latter will, therefore, be large.

In view of these considerations, it has been found desirable to consider variations in the elements of the trajectory due to variations from the normal conditions as functions of the variations from the normal conditions and to solve the differential equations of the variations, using the same principles of numerical integration as are used in the solution of the differential equations of the trajectory.

Equations of the Variations.—Taking x and y as the coördinates at the time t of the original trajectory of which the differential equations are (9) and (10), let us assume that the coördinates of the modified trajectory corresponding to the same time are $x+\xi$ and $y+\eta$, ξ and η representing the variations, due to some cause other than wind, in the conditions under which the original trajectory was constructed.

Variations due to wind affect the relative velocity between the projectile and the air and, therefore, the value of E, independently of the variations in x' and y' and will be considered in a later section.

Under this assumption the coördinates of the modified trajectory should satisfy the equations:

$$(13) \qquad x''+\xi''=-(E+\Delta E)\ (x'+\xi')$$

$$(14) \qquad y''+\eta''=-(E+\Delta E)\ (y'+\eta')-g.$$

If we combine these with equations (9) and (10), and neglect all terms consisting of products of the small quantities ξ, η and their derivatives, and ΔE, we obtain upon solution for ξ'' and η''

$$(15) \qquad \xi''=-E\xi'-x'\Delta E$$

$$(16) \qquad \eta''=-E\eta'-y'\Delta E.$$

On substitution of the value of E obtained from equation (9), transposition and division by x',

$$(17) \qquad \frac{x'\xi''-x''\xi'}{x'^2}=-\Delta E$$

$$(18) \qquad \frac{x'\eta''-x''\eta'}{x'^2}=-\frac{y'}{x'}\Delta E.$$

Since the first members are the derivatives of ξ'/x' and η'/x' respectively, we may express the integrals as follows:—

$$(19) \qquad \frac{\xi'}{x'}-\frac{\xi_0'}{x_0'}=-\int_0^t \Delta E dt$$

$$(20) \qquad \frac{\eta'}{x'}-\frac{\eta_0'}{x_0'}=-\int_0^t \frac{y'}{x'}\Delta E\, dt$$

or,

$$(21) \qquad \xi'=\frac{x'\xi_0'}{x_0'}-x'\int_0^t \Delta E\, dt$$

$$(22) \qquad \eta'=\frac{x'\eta_0'}{x'}-x'\int_0^t \frac{y'}{x'}\Delta E\, dt.$$

Here ξ_0' and η_0' represent the amounts by which the initial components of velocity differ from x_0' and y_0' respectively.

This set of equations like (9) and (10) may be integrated by the method of numerical integration, but we must first obtain an explicit relation between ΔE and ξ', η' and η.

Effect of the Variations on E.—Since by equation (11) $E=\frac{GH}{C}$ we may write approximately,

$$(23) \qquad \frac{\Delta E}{E}=\frac{\Delta G}{G}+\frac{\Delta H}{H}-\frac{\Delta C}{C}.$$

Again $$\Delta G=\frac{dG}{dv}\Delta v,\quad \frac{\Delta G}{G}=\frac{d\ \log_e G}{dv}\Delta v$$

and $$\Delta H=\frac{dH}{dy}\Delta y,\quad \frac{\Delta H}{H}=\frac{d\ \log_e H}{dy}\Delta y$$

we may write the equation,

$$(24) \qquad \frac{\Delta E}{E}=\frac{d\ \log_e G}{dv}\Delta v+\frac{d\ \log_e H}{dy}\Delta y-\frac{\Delta C}{C}.$$

Now, (25)

$$\Delta v=\Delta\sqrt{x'^2+y'^2}=\frac{\Delta(x'^2+y'^2)}{2\sqrt{x'^2+y'^2}}=\frac{2\,x'\xi'+2\,y'\eta'}{\sqrt{2\,x'^2+y'^2}}=\frac{1}{v}\ (x'\xi'+y'\eta')$$

and $\Delta y=\eta$.

Consequently we may write,

$$(26) \qquad \Delta E=E\left(\frac{1}{v}\frac{d\ \log_e G}{dv}\ (x'\xi'+y'\eta')+\frac{d\ \log_e H\eta}{dy}\right)+E\frac{\Delta C}{C}.$$

The first term of the second member of this equation gives the part of ΔE due to variations in the components of the velocity and of the height. The last term gives the part due to variations in the ballistic coefficient including variations in the air density. Equation (26) is based on the assumed law of retardation as given by Table I. and the assumed law of air density as given in Equation (2). There is no trouble, however, in making differential corrections for variations from these assumed laws.

The term $\frac{d\ \log_e G}{dv}$ or $\frac{1}{vG}\cdot\frac{dG}{dv}$ is found from the G function Table I. and tabulated with $\frac{v^2}{100}$ as an argument in Table III. below. If we assume for H the exponential formula given by equation (2) we have $\frac{d\ \log_e H}{dy}=-\cdot 0001036$ a constant.

TABLE III.

Values of $\frac{1}{vG}\cdot\frac{dG}{dv}$

For use in making differential corrections.

Argument $v^2/100$ (v in metres). The expressions $\cdot 0_3 423$, $\cdot 0_4 378$, etc. mean $-\cdot 000423$, $\cdot 0000378$, etc.

Integration of the Differential Equations of the Variations.—By using equation (21) with (22) and (26) we make a step-by-step numerical integration for any assumed variation. The system requires a separate integration corresponding to each assumed variation of conditions in each trajectory. It is always assumed that the original trajectory has been constructed and that we know its elements. The integration may proceed forward or backward from any point, as at the muzzle or the end of the trajectory, where we know or may estimate the values of disturbing variations and the effects produced by them.

Bliss's Method.—As may be inferred, the method for computing differential corrections, just described, involves a large amount of work. A method discovered by Professor G. A. Bliss and improved by Dr. T. H. Gronwall, in which use is made of a system of linear differential equations adjoint to the linear differential equations of the variations, as given by equations (13) and (14), reduces the work required to the extent that after the original trajectory has been computed, one numerical integration of the system will suffice for the computation of the corrections for all the variations. The method is, therefore, invaluable when a large number of differential variations are to be worked out.

Tabulated Differential Corrections in Ballistic Tables.—Certain differential corrections are conveniently tabulated, in separate columns of ballistic or range tables as follows:—

(*a*) Range and deflection corrections for the rotation of the earth as functions of the geographical latitude of the gun, azimuth of the plane of fire, and the three standard parameters of the trajectory, muzzle velocity, angle of departure and ballistic coefficient.

(*b*) Corrections in range for variations in assumed air density throughout layers at convenient altitude intervals.

(*c*) Corrections in range for a component of wind in the plane of fire, throughout layers at convenient altitude intervals.

(*d*) Corrections in deflection for a component of wind at right angles to the plane of fire throughout layers at convenient altitude intervals.

In addition, corrections for variations in initial components of muzzle velocity, and variations in ballistic coefficient, may be obtained by interpolation in the main columns of the tables. A variation in air density at the gun may be corrected for in this way by determining its effect on the ballistic coefficient and making the corresponding interpolation in the table. This assumes that any change in air density at the gun is accompanied by a corresponding change aloft according to the law given by the H function. Of the first list of variations referred to, more will be said below.

Effect of Wind.—Any wind acting on the projectile in flight may be resolved into two components: one along and the other perpendicular to the plane of fire. It is convenient to do this in considering the effects of winds, and we thus have range winds and cross winds.

Uniform Range Wind. Corrections due to rear or head winds may be handled by equations (21) and (22) and (26). In using these equations we must merely remember to increase or decrease the velocity with respect to the ground by the wind velocity when it is desired to get from the Tables, I. or III., the corresponding functions. Aside from this, a correction due to wind may be handled in the same manner as a correction due to variations in any of the initial conditions, air density, etc.

Variable Wind.—The direction and velocity of the wind will seldom be uniform throughout the trajectory. The velocity of the wind and also its direction near the surface of the earth is frequently influenced by local causes, such as the presence of hills, trees, houses, etc., to such an extent as to give no indication of the true average values during the flight of the projectile. Under normal conditions the wind may change both in direction and velocity as we go upward. Cases in which there is complete reversal of the wind well within the maximum ordinate of the trajectory are not unusual. The change in direction may also be accompanied by a change in velocity. In the preparation of range tables it is necessary to correct in some way for the effect of this sort of wind. The method usually followed is to divide the air above the earth's surface into zones of height, say 250 metres. By observation, the direction and velocity of the wind in each zone are determined.

For any assumed trajectory let ΔR_0 be the range correction of a uniform range wind of 1 metre per second, acting throughout. Now, dividing the trajectory into zones of height (as shown in fig. 4) let ΔR_1 be the total range effect produced by a wind of 1 metre per second blowing in the first zone and no wind in the other zones. The ΔR_1 correction can be computed by numerical integration of equations (21) and (22) to the limits of the zone, using the 1 metre wind. With the corrections found for that point, the integration is continued in still air until the projectile again enters the first zone. With these last corrections and the wind again acting, the integration is continued and the final correction ΔR_1 determined.

In the same manner the correction ΔR_2 for a wind of 1 metre per second, acting in the second zone, and no wind in the other zones, is determined. We then have

$$(27)\qquad \Delta R_0 = \Delta R_1 + \Delta R_2 + \ \ldots + \Delta R_n$$

If u_1, u_2, u_3, etc., represent the wind velocities in the various zones, and ΔR represents the total range effect due to them, we may put approximately

$$(28)\qquad \Delta R = u_1 \Delta R_1 + u_2 \Delta R_2 + \ldots + u_n \Delta R_n$$

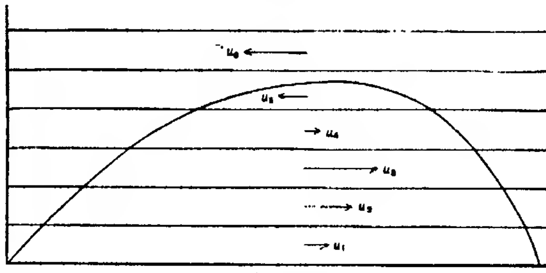

FIG. 4

In this equation some of the winds may be rear and others head, so the terms should be taken with their proper signs.

Weighting Factors and Ballistic Wind.—If we place

$$(29)\qquad f_1 = \frac{\Delta R_1}{\Delta R_0},\quad f_2 = \frac{\Delta R_2}{\Delta R_0}\ \text{etc.}$$

the ratios f_1, f_2, etc., are called weighting factors since they show the fractional part of the total wind effect that is produced in each zone. Using these factors we may write

$$(30)\qquad R = (f_1 u_1 + f_2 u_2 + \ldots\ldots\ldots f_n u_n)\ \Delta R_0$$

The factor in brackets is the ballistic wind. It is the wind which, if blowing uniformly throughout the trajectory, would produce the same range effect that is produced by the variable winds actually blowing.

In the preceding discussion we have considered only rear or head, that is range, winds.

Cross Wind.—In the discussion of the trajectories so far given, no account has been taken of forces which tend to move the projectile from the plane of fire. Aside from drift, the principal cause of deflection from the plane of fire is the existence of a cross wind component. While the deflection due to drift is constant for any one trajectory for a given gun and projectile and is determined once for all by experiment, that due to cross wind varies with the velocity of the wind as well as with the elevation and azimuth of the gun. If we let z represent the distance in metres the projectile is blown from the plane of fire at any instant by a cross wind w, distances and winds to the right being taken as positive, we will have z', the velocity from the plane of fire, and z'', the acceleration produced by the component of air resistance normal to the plane of fire. The velocity of the projectile with respect to the air will be $z' - w$.

Now it will be sufficiently exact to consider the motion perpendicular to the plane of fire in the same manner in which we considered the horizontal motion in the plane of fire in equation (9), remembering that the velocity with respect to the air is $z' - w$. We may then write,

$$(31)\qquad z'' = -E(z' - w).$$

Combining this equation with the relation $x'' = -E\ x'$ from (9) we obtain after reduction and division by x'^2,

$$(32)\qquad \frac{z''\ x' - x''\ z'}{x'^2} = -\frac{wx''}{x'^2}$$

Upon integration from 0 to t this becomes,

$$(33)\qquad \frac{z'}{x'} = \frac{w}{x'} - \frac{w}{x_0'}$$

or

$$(34)\qquad z' = w\left(1 - \frac{x'}{x_0'}\right)$$

Integrating again we obtain,

$$(35)\qquad z = w\left(t - \frac{x}{x_0'}\right)$$

which makes the total deflection at the end of the trajectory,

$$(36)\qquad Z = w\,T - \frac{w}{x_0'}X.$$

In this expression w T is the total motion of the air with respect to the ground in the time of flight T. The deflection of the projectile is less than the motion of the air by the amount $\frac{w}{x_0'}X$, which is the deflection at the total range X that would be caused by a change of azimuth by the angle whose tangent is $\frac{w}{x_0'}$.

Cross wind weighting factors and the ballistic cross wind are determined in the manner described for range winds.

Effect of Curvature of the Earth.—While in the example of the numerical integration of a trajectory given above, and also in the construction of ballistic tables, the effect of curvature of the earth is not taken into account, it would be quite possible, still retaining

the system of rectangular coördinates with the x axis horizontal and the y axis vertical at the gun, to take account of the effect of curvature, both as it affects the direction lines of gravity and the height of site. Corrections due to curvature become important only at long ranges and then the most important is that due to height of site or the curvature of the earth away from the x axis. The correction angle at the gun due to curvature is one-half the angle at the centre of the earth subtended by the range.

Correction for Rotation of the Earth.—If a projectile is fired due east or west at the equator, it has, at the muzzle of the gun, not only the initial velocity with respect to the earth but also the velocity of the earth at that point. If the motion of the earth were one of translation alone, this fact would have no effect on the trajectory: but since the earth rotates around its axis and the rising projectile gets further and further away from this axis, an effect is produced upon the trajectory. This may be made more plainly evident if we assume the projectile to be fired vertically at the equator. With a motionless earth or one moving in right lines the projectile would fall back to the point from which it was fired. With a rotating earth the projectile has, at the muzzle, the vertical velocity given it by the gun, as well as the horizontal velocity of the earth's surface; as it rises it retains the latter velocity at all heights which it reaches. If we now consider points on that radius of the earth which passes through but above the muzzle of the gun we readily see that they have horizontal velocities due to the rotation of the earth in excess of those of the projectile at corresponding heights. It is evident, therefore, that the projectile will lag behind this radius and will fall to the earth west of the gun. A similar range correction will exist if the gun is fired east or west at the equator at any angle of elevation. The value of the correction is proportional to the angular velocity of the earth and the diameter of the equatorial section and depends besides upon the elements of the particular trajectory.

If the gun is fired along a parallel of latitude we have a somewhat similar condition, differing principally in that the velocity of the earth's surface is now less in the proportion cos l, where l is the latitude. Now if the gun at the equator were fired along a meridian, the correction just referred to would no longer exist as a range correction but would become a deflection correction. For a gun fired at any point of the earth it may be shown mathematically that the corrections due to the causes above may be represented by functions of the form

For range,	$A \cos l \sin a$
For deflection,	$D \cos l \cos a$

where l is the latitude, a is the azimuth of the plane of fire measured from the south through the west, and A and D are functions whose values depend upon the trajectories.

The above corrections for both range and deflection arise from the lag of the projectile behind the surface of the earth due to its greater distance from the centre of the earth. Another consideration which gives rise to an additional deflection is the change in the velocity of the earth's surface with latitude. A projectile fired from the pole will be displaced by an angular amount depending upon the time of flight and hence by a lateral amount approximately proportional to the product of the time of flight and the range. For a latitude l the deflection due to this cause is equal to that at the pole multiplied by sin l and may be represented by

$$B \sin l.$$

A rough value of B is ΩXT, where Ω is the angular velocity of the earth. The total displacements due to rotation of the earth are, therefore, given by the following equations:—

(37) Range displacement, $\Delta X = -A \cos l \sin a$

(38) Lateral displacement, $\Delta Z = B \sin l + D \cos l \cos a$,

where A, B, and D are computed by integration from the data of each trajectory. It is in this way that range and deflection corrections for the rotation of the earth are worked for incorporation in ballistic tables. If air resistance is neglected the values of A, B, and D may be worked out without integration and are:—

(40) $A = \Omega XT\ (\cot \omega - \frac{1}{3} \tan \phi)$

(41) $B = \Omega XT$

(42) $D = \frac{1}{3}\, \Omega XT \tan \phi.$

Since A changes sign at $\cot \omega = \cot \phi$ (in vacuum) or at $\phi = 60°$, it follows that for this angle of departure in vacuum there is no range correction for rotation at any latitude or azimuth.

However, the resistance of the air markedly affects both range and deflection corrections due to the earth's rotation, and the approximate equations (40) to (42) applicable to trajectories in vacuum are not adequate for these corrections with long trajectories.

Variations from Standard Air Density.—In case the observed air density does not follow closely enough the assumed law of equation (2) we may divide the air into zones of height, as for variable wind, and determine air density weighting factors and a ballistic air density. The range correction for a variation in air density of, say, 10% from the normal is first worked out, it being assumed that the law of air density given by equation (2) holds throughout the trajectory. The partial corrections due to the same percentage variation in each zone are then worked out. The ratios of these partial corrections to the total correction are the weighting factors. When the weighting factors are multiplied by the observed densities in corresponding zones, corrected to their value at the ground following the normal law, and the sum of the products for all the zones is taken, we have the ballistic air density.

Effects of Temperature Variations.—The temperature of the air affects both its density and its elasticity. In so far as it affects density, corrections in ballistic results, due to changes in temperature, are accounted for by the density correction, and when once the density is known no further reference need be made to temperature. The effect of temperature on the elasticity of the air is in addition to and almost independent of its effect on density. Elasticity of the air may be measured by the velocity of sound therein. This is known to increase as the square root of the absolute temperature and is only slightly affected by density.

In fig. 1 of the B curve above, note was made of the disturbance in the neighbourhood of the velocity of sound. If the velocity of sound is moved to the right or left on the V-axis by a change of temperature, the B curve will be similarly displaced and hence the E function used in equations (9) and (10) will be changed. With the quadratic resistance law, the B curve would be a right line parallel to the V-axis, and no change would be caused in B, G or E by a change of temperature.

Trajectories used for ballistic table data are worked out for normal temperature

$$15° \text{C.} = 59° \text{F.} = 288° \text{A.}, \text{ and are so tabulated.}$$

Standard Temperature.—It would be more logical if trajectories were worked out under some law of temperature gradient, similar to that assumed for the density gradient, equation (2). Taking account of the "gas law" derived from Boyle's and Charles' laws, the density law given by equation (2) and the theorem of static equilibrium which requires the difference in pressure at altitude y and sea level to be due only to the weight of the intervening layer, A. A. Bennett has arrived at the following formula for temperature aloft:—

$$\text{Temperature} \begin{cases} °\text{C.} = 50 - 35 \times 10^{\cdot 000015y} \\ °\text{F.} = 122 - 63 \times 10^{\cdot 000045y} \end{cases}$$

This represents fairly mean midsummer temperature in the United States. For mean midwinter temperatures subtract 12·5° C. = 22·5° F. throughout. Corrections may be worked out to enable one to pass from the tabular data, based on constant temperature, to data based on the temperature gradient given by these equations.

Rotation of Projectiles.—Thus far we have considered the motion as merely that of a material point, or at any rate we have taken no account explicitly of the change in the air resistance which may result from the oblique presentation of an elongated projectile. If projectiles were spherical, as formerly, there could be but one presentation or one section exposed to air pressure, though the projectile might rotate in any direction.

Modern projectiles are given a motion of rotation by the rifling to prevent them from tumbling end over end and thus meeting with vastly increased and irregular air resistance. A projectile so designed as to place the "centre" of pressure in rear of the centre of mass, would doubtless travel head-on without having rotation. Attempts have been made to design such projectiles with some success as far as the ability to travel head-on is concerned; but it has always been necessary to increase the total head-on resistance, by the addition of a tail or similar device, to such an extent as to make them inferior to projectiles stabilized by rotation. Projectiles of this type are now used as bombs to be dropped from aircraft but are not fired from guns.

Yaw of the Projectile.—It has been determined by experiments that elongated projectiles do not always make round holes through cardboard screens called "jump cards" placed at short distances in front of the gun. By placing a sufficient number of these cards, it is found that the holes change in regular cycles, from greater to less and again to greater elongation. For a given round, certain positions of the jump cards, if thickly spaced, give holes of the greatest elongation, corresponding to the maximum yaws of the projectile, and certain other positions give holes of the least elongation corresponding to the minimum yaws. If jump cards are placed from near the gun up to 500 or 600 yd. from it, it will be found that the maximum yaws will diminish in value, the first one that appears in front of the gun being the greatest. By yaw is understood the angle between the direction of motion of the centre of gravity and the axis of the projectile.

In the *Aerodynamics of a Spinning Shell* by R. H. Fowler, E. G. Gallop, C. N. H. Lock and H. W. Richmond, F.R.S. (*Phil. Trans.*, series A, vol. 221), the authors present a very complete analysis of British jump-card experiments conducted by them. While the existence of initial instability of projectiles had long been known, knowledge of its laws and its effects on drift range and accuracy were vague, prior to these British experiments made in 1918.

Causes of Yaw.—A projectile fitting perfectly in the gun and having the centre of gravity of every cross section on the axis of figure, will move in the direction of that axis after leaving the muzzle, unless some force should start an angular motion of the longer axis. For the short distance with which we are here concerned the effect of gravity in curving the trajectory away from the axis is neglected. A projectile not fitting perfectly, or having its axis of figure not coincident with its dynamic axis, will yaw slightly in the gun. On leaving the muzzle it may receive an additional yaw from the powder

pressure against the base when the front bearing is unsupported, from the jump of the gun and from the powder blast.

Furthermore, at this point the air resistance begins to act in retarding the projectile. The action line of the resultant air pressure on a yawing projectile intersects the axis at a point in front of the centre of gravity. The resultant air resistance, therefore, exerts a moment around an axis through the centre of gravity, in such a direction as to increase the yaw. We then have a motion similar to that of a spinning top or gyroscope when an angular motion is given to the axis of spin, except that we have in addition a rapid motion of the centre of gravity.

In other words, the projectile has a motion of translation accompanied by precession and nutation. The motion of the point projected on a plane through the centre of gravity and normal to the trajectory, describes a rosette, as shown in fig. 5.

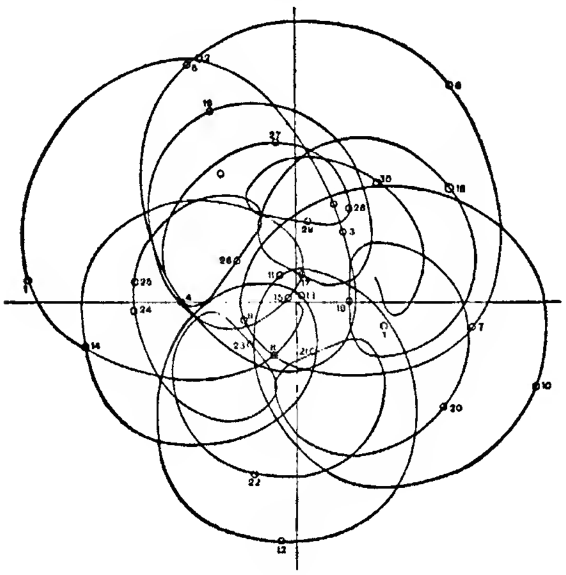

Fig. 5.

Condition of Stability.—If the spin is insufficient the air moment may cause the projectile to tumble. The condition of stability may be expressed by the following equation:—

$$s=\frac{A^2\,N^2}{4B\ \mu}$$

where

δ, is the stability factor. Its value must be greater than 1·0 if the projectile is not to tumble, and not lower than 1·5 or 2·0 for modern projectiles, if excessive yaws are to be avoided,

A, the moment of inertia of the projectile about the axis of spin,

B, moment of inertia about an axis at right angles through the centre of gravity,

N, the velocity of rotation about the longer axis in radians per second,

U, sin δ, the moment of the air resistance around an axis through the centre of gravity at right angles to the longer axis when the yaw is δ,

The value of δ depends upon the air resistance, but is nearly independent of α for small yaws.

δ, the angle of yaw.

By an analysis of the results obtained in British and American jump-card experiments, R. H. Kent has determined that the value of the first maximum yaw outside the gun may be computed in terms of the stability factor and the yaw inside the gun by the following equation:

$$\alpha_1=\frac{2I}{A}\quad\frac{\epsilon}{\left(1-\frac{1}{s}\right)^{\frac{1}{2}}}$$

where α is the first maximum yaw

ϵ. the yaw in the gun.

Figure 6 shows the values of α_1 in terms of s for a value of $\frac{I}{A}=8$ and $\epsilon=0^\circ{\cdot}2$.

It appears from this relation that the maximum yaw in front of the gun is principally due to the yaw in the gun, and that it is very little affected by the pressure of the powder gas, during the time the projectile is emerging from the muzzle, by the jump of the gun, or by the blast in front of the muzzle.

Orientation of the Yaw.—The plane of yaw contains the path of the centre of gravity and the axis of the projectile. The orientation of the yaw is the angle between this plane and the vertical plane containing the path of the centre of gravity. It is determined by measuring the angle between the traces of these two planes on the jump card. The precessional motion consists of rotation of the plane

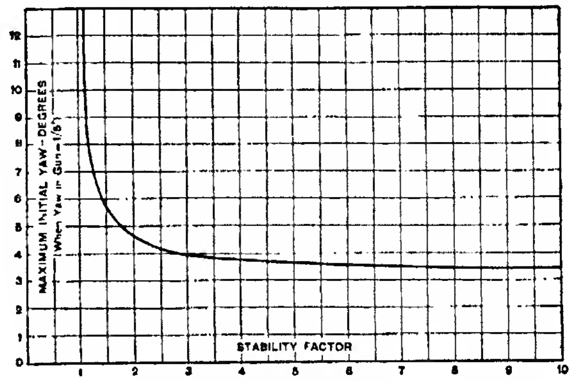

Fig. 6.

of yaw around the path of the centre of gravity, while the motion in nutation consists of oscillations around an axis through the centre of gravity normal to the plane of yaw.

For a small yaw not accompanied by nutations the rate of change of orientation is,

$$\alpha'=\frac{AN}{2I}$$

The motion in nutation causes abrupt changes in this rate in the neighbourhood of the minimum yaws.

Damping of the Yaw.—Reduction in the yaw of the projectile, as it proceeds down the range, is principally due to the following factors: (*a*) The component of the air resistance normal to the direction of motion of the yawing projectile causes motion of the centre of gravity in the direction of the yaw. The effect is a virtual reduction in the yaw accompanied by a helical motion of the centre of gravity; (*b*) the resultant angular motion of the axis of the projectile due to precession and nutation sets up an air-resistance couple which opposes that motion, and which is quite distinct from the air-resistance moment which causes the main part of the initial maximum yaw. The effect of the couple is first to damp out the nutations and finally to reduce the yaw; (*c*) as the velocity of the projectile decreases, the air resistance also decreases. The consequent reduction in the air resistance moment on a yawing projectile causes a reduction in the maximum yaws.

Effect of Yaw on Range and Accuracy.—The resistance of a yawing projectile is very much greater than that of a projectile moving in the direction of its axis. Experiments made by G. F. Hull and L. J. Briggs in an air stream indicate that at a velocity of 200–300 metres per second the head-on resistance of a projectile of modern form yawing 15° is two to two and one-half times that of the same projectile moving in the direction of its axis. A considerable yaw in front of the gun will, therefore, cause a rapid reduction in the velocity and a reduction in range.

It is readily seen that a variation in initial yaw between rounds will cause bad range dispersion. The same is true of dispersion in deflection. It may be stated that irregularity in initial yaw, whatever may be its cause, forms one of the principal factors in dispersion of fire.

Drift.—As the projectile proceeds along the trajectory, its axis tends to remain parallel to its original direction at the gun. Since the effect of gravity causes the trajectory to curve toward the earth, there is a gradual increase in the angle between the axis of the projectile and the trajectory. This yaw, due to gravity, is quite distinct from the initial yaw described above and does not begin to have an important effect on the flight of the projectile until after the greater part of the initial yaw has been damped out.

A yaw having been developed by gravity, the air-resistance moment μ sin s, tending to rotate the spinning projectile in the plane of yaw, causes motion in a plane at right angles. The effect with right hand rotation of the projectile, is to cause the point of the projectile to move at first to the right of the plane of fire and at a later period downward[4] the projectile being bodily displaced by the component of air resistance acting normal to the direction of motion, on the side presented by the yaw. The initial instability and the drift are phenomena of like nature. While the initial instability is caused by a suddenly applied yaw, or a high rate of change of yaw, and is accompanied by a rapid motion in precession and nutation, the drift is caused by the gradual yaw due to the action of gravity on the projectile, and is accompanied by a very much slower motion in precession without nutation. (W. H. T.)

BALLOON: *see* AERONAUTICS.

BALTIMORE (*see* 3.288).—The pop. of Baltimore, the 8th city of the United States in number of inhabitants, increased in the decade 1910–20 from 558,485 to 733,826, of which number 108,390 in 1920 were negroes as compared with 84,749 in 1910. The 31·4 % increase in the total population represented in part a normal growth or one caused by the establishment of new industries, and in part an annexation (Act of Legislature of 1918) of 63.13 sq. m. containing several thickly settled manufacturing districts. This accession of territory increased the taxable basis of the city from $915,433,444 in 1918 to $1,086,349,852 in 1920.

Manufactures.—In 1914, Baltimore ranked 11th in the value of its manufactured products and 8th in the average number of industrial wage-earners among the 130 leading American cities. The capital invested in its manufactures was $177,301,000; the value of its output was $215,171,530, and its wage-earners in manufacturing plants numbered 73,769. There were 21 industries which exceeded one million dollars in value of product; the clothing industry led with products valued at $44,482,136, while copper, tin and sheet iron ($18,842,186), printing and publishing ($10,283,775), cars and general shop construction ($10,038,911), slaughtering and meat packing ($9,503,883), and canning and preserving ($7,789,125) followed in the order named. Unofficial figures (Board of Trade, Baltimore City) showed that from June 1 1919 to May 31 1920 100 new industries and 134 expansions of old industries increased the number of persons employed by 39,850 and added $72,612,200, or 40 %, to the manufacturing capital of the city. This great increase may be attributed to differential freight rate on goods from the west, deep-water manufacturing sites, steamship connexions, coastwise and foreign, and abundance of labour. Baltimore is a popular city with labour because in normal times its markets are notably cheap, and the continuance in Maryland of the ground-rent system makes possible the purchase of homes by labouring men on easy terms. In 1919 permits were granted for the construction of 3,700 two- and three-storey dwellings. Six hundred building and loan associations make it possible for labouring men to purchase easily houses of this type without hardship.

Commerce.—As an export port, Baltimore advanced notably in the amount of its business. In 1908 its exports amounted to $82,113,-496; its imports $23,722,045. In 1918 the total value of domestic exports was $300,144,011; in 1920 $381,532,145. Its imports[1] in 1918 were $35,982,665, and in 1920 were $69,885,165. In 1918 it exported 51,085,209 lb. of bacon and ham; 156,141,175 lb. of copper; 10,408,382 bus. of oats; 17,158,200 bus. of wheat and 76,879,176 lb. of leaf tobacco. In 1919, its wheat exports had increased to 25,501,-321 bus. and its leaf tobacco to 149,529,865 pounds. Its principal imports in 1919 were copper (22,540,577 lb.), corkwood and waste (7,338,391 lb.) and mineral oil (200,298,000 gal.). In 1920, 1,809 vessels engaged in foreign trade (tonnage 5,218,089) cleared the port of Baltimore.

Municipal Improvements.—The physical characteristics of Baltimore were much altered during the decade 1910–20. By a paving loan of 1906, and by a special paving tax of 1912, funds were provided for the conversion of a "cobblestone city" into one with 210 m. of modern smooth-paved streets at a cost of $9,500,000. Three concrete tubes were constructed in the bed of Jones Falls, which had become an unsightly open sewer, and into these the stream and an additional flow of stormwater sewage were directed and carried through the city for a mile-and-a-half. On top of these tubes a highway was constructed, known as the Fallsway, which relieved the congestion of north and south traffic between the water front and the up-town railroad yards. At a cost of $23,500,000 the main work of installing a new sewerage system, begun in 1905, was completed in 1916. A dam at Lock Raven (2,000,000,000 gal. capacity) and a filtration plant at Montebello for impounding and purifying the Gunpowder river water supply were constructed. A general "City Plan," although only partly carried out by 1920, provided for the best treatment of all city utilities, streets, harbour, parks, railways, from an artistic as well as from a utilitarian standpoint. A civic centre was provided and Mt. Vernon and Washington Places, the setting of the Washington Monument, were completely changed in their landscape and decorative features. A boulevard, almost completely surrounding the city, connects the several parks.

Annexation and Loans.—One of the most important of all changes was the passage in 1918 of an Act of the Maryland Assembly by which to the 32.19 sq. m. of Baltimore territory were added 51.83 sq.m. of land and 11.30 sq.m. of water, making the total area 95.32 sq.m. and adding about 100,000 persons to the population. At the Nov. election of 1920, the people voted overwhelmingly in favour of four improvement loans, aggregating $51,750,000, the several items of which were the Public Improvement Loan (schools, sewers, streets and bridges, harbour improvements, etc.) $26,000,000; the Water Supply Loan $15,000,000; the Port Development Loan $10,000,000; the Municipal Hospital Loan $750,000.

Finance.—Fifty-seven Baltimore banks and trust companies, exclusive of private banking firms showed Jan. 1 1920 aggregate resources of $522,783,000 and deposits of $414,453,000. In 1919 Baltimore was the 11th city in the country in bank clearings with a total of $4,343,446,572, a gain of 29·4 % over the preceding year and of 91·6 % over 1917.

Education.—Notable progress was made by Johns Hopkins University in the decade 1910–20. The public library system of the city (the Enoch Pratt Free Library) which in 1910 had one central building, 12 branches and two stations, reported in 1920 the erection of six additional branches, and that plans had been accepted for the erection of four more branch buildings.

Religion, Charity, Hospitals.—In 1916 there were 494 religious organizations in Baltimore owning 455 places of worship, and church property valued at $16,167,350. The total church membership was 296,599, approximately one-half the population. In numbers the Roman Catholic Church led with 137,730 members (100,397 in 1906), and following it in the order named came the Methodist Episcopal Church 30,217 (24,605 in 1906), the Baptist Church (National Convention, Coloured) 24,648 (16,081 in 1906), and the Protestant Episcopal Church 17,209 (16,812 in 1906). In 1915 all the charitable agencies formed an administrative association, the Baltimore Alliance of Charitable and Social Agencies, which coördinated the work of the individual organizations.

History.—The mayor of Baltimore from 1907 to 1911 was J. Barry Mahool, Democrat. From 1911 to 1918 the mayor, James H. Preston, and the City Council were Democratic. A Republican mayor, William F. Broening, was elected in 1918, but the City Council continued to be Democratic. In the World War the Baltimore militia organizations, the 4th and 5th Maryland Regts., were combined with the 1st Maryland to form the 115th Inf., U.S.A.; the Md. F.A. (3 batteries) became the 2nd batt. of the 110th F.A., U.S.A. Several smaller units followed these into the 29th Division and were trained at Camp McClellan, Ala. The infantry units of this division saw service at the front in France. Sixteen thousand five hundred men were raised by selective draft. Many of these received their training at Camp Meade, Md., and saw service at the front with the 79th Division, as the 313th Infantry Regiment.

Preston, Mayor, 1918; Statistics of Baltimore Board of Trade, 1920.
(L. C. W.)

BANBURY, SIR FREDERICK GEORGE, 1ST BART. (1850–), British politician, was born in London Dec. 2 1850. He was educated at Winchester, and afterwards adopted a City career. He entered the Stock Exchange, and subsequently figured in various capacities as a director of companies. He successfully contested Peckham as a Conservative in 1892, and established his reputation in the House of Commons as a constant critic on business matters and also as an expert in parliamentary procedure. In 1902 he was created a baronet. He lost his seat in the general election of 1906, but was elected a few months later as one of the members for the City of London (reëlected 1918). In 1916 he was created a privy councillor, and in 1917 became chairman of the Great Northern railway.

BANCROFT, HUBERT HOWE (1832–1918), American historian (*see* 3.300), died at Walnut Creek, Cal., March 2 1918. He published in 1909–10 *The Book of Wealth* and in 1912 *Retrospection, Personal and Political*, the latter giving an account of his labours.

BANCROFT, SIR SQUIRE (1841–), English actor and manager (*see* 3.300), made his last regular appearance on the stage as Count Orloff in a revival of *Diplomacy* at the Garrick theatre in 1893. The company were summoned to play before Queen Victoria at Balmoral Castle in Oct. of that year. He subsequently only appeared occasionally at special performances, the latest and most notable of which was at His Majesty's theatre, London, in Dec. 1918 when he played Triplet in *Masks and Faces*.

His wife, LADY BANCROFT (1839–1921), died at Folkestone, May 22 1921. She had first appeared on the stage under her maiden name of Marie Effie Wilton at Manchester as Fleance in *Macbeth* and as Prince Arthur in *King John* as

[1] Import figures are for the U.S. Customs District of Maryland, of which the Port of Baltimore business represents approximately 95 %.

early as 1847. She made her début in London in 1856 with Charles Dillon at the Lyceum theatre as Henri in *Belphegor.* Her brilliant career as an actress, from the time when in 1865 she went into management at the Prince of Wales's theatre, and married Mr. (afterwards Sir Squire) Bancroft in 1868, came to a close in 1885, when she and her husband retired from the stage; but Lady Bancroft reappeared with him in the *Diplomacy* revival of 1893, and twice subsequently made a single appearance at a special matinee, the last occasion being the benefit performance for Miss Nellie Farren in March 1898.

BANDELIER, ADOLPH FRANCIS ALPHONSE (1840–1914), American archaeologist (*see* 3.311), died at Madrid March 19 1914. His last published works were *The Islands of Titicaca and Koati* (1910) and *The Ruins of Tiahuanaco in Bolivia* (1912).

BANERJEA, SIR SURENDRANATH (1848–), Indian orator, political reformer and journalist, was born Nov. 10 1848, a member of the Rarhi sub-caste of Kulin Brahmans, and the second son of a medical practitioner in Calcutta. Passing for the Indian civil service at the open competition of 1870, he was posted to Sylhet as assistant magistrate but, at the expiry of two years, was compulsorily retired on a small compassionate pension, on account of a technical irregularity—a decision since admitted generally to have been unduly harsh. He then opened a small school in Calcutta which soon expanded into the well-known Ripon College. His work as a political reformer began in 1876 when he founded the Calcutta Indian Association, and three years later he became editor of the *Bengalee* newspaper. In subsequent years he became the centre of many stormy episodes. He was one of those who established the Indian National Congress in 1883, and presided over the Poona session of 1895 and again at the meeting at Ahmedabad in 1902.

From 1876 to 1899 he served on the Calcutta corporation, when he resigned with 27 other leading commissioners as a protest against the changes introduced by the Calcutta Municipal Act. In 1893 he was elected to represent the corporation on the Bengal Legislative Council, and was twice returned to the central Legislature as member for Bengal. He gave evidence in 1897 before the Royal Commission on Indian Expenditure aud frequently visited England in connexion with deputations and political missions. Vehemently opposing the administrative partition of Bengal effected by Lord Curzon in 1905, he supported the boycott of foreign goods and the movement in favour of "national" education which arose from the upheaval. He always exhibited, however, a preference for constitutional agitation, and was among the first to welcome the Montagu-Chelmsford reforms. Severing his association with the Congress, which had passed under "extremist" control, he formed an "Indian Liberal" organization, and came to London in 1919 to present the case for his party before the Joint Parliamentary Committee, subsequently accepting office as Minister for Local Government and Sanitation in Bengal. A knighthood was conferred upon him in Jan. 1921. Possessed of a remarkable knowledge of the English language and literature, he had earned by his eloquence the title of the Gladstone of India.

(H. E. A. C.)

BÁNFFY, DEZSÖ [Desiderius], Baron (1843–1911), Hungarian statesman (*see* 3.315). In 1906 Bánffy, who had joined the coalition in opposition to the Government, broke with it on the military questions at issue with the King-Emperor, which he wished to eliminate, and in 1908 he became leader of the progressive elements and, as president of the Franchise League, began an agitation for universal, secret and equal suffrage (*see* 13.920, 921). In 1910 he became president of the Reform Club. He died May 24 1911.

BANG, HERMANN JOACHIM (1858–1912), Danish author (*see* 3.315), died Jan. 29 1912. In 1910 a volume of essays appeared, *Masker og Mennesker*, followed in 1911 by a volume of short stories, *En deilig Dag.* His collected works were published in six volumes in Copenhagen and Christiania (1912).

See F. Poppenberg, *Nordiske Porträts—Hermann Bang* (1912).

BANKING (*see* 3.334).—I. United Kingdom.—British banking during 1910–21 underwent vast changes, not the least of which was seen in the direction of amalgamation. But even apart from that, the banks had grown in size, in importance, and in the extent of the territory covered by their branches. During this period, the great joint stock banks, which had generally been considered ultra-conservative in their methods, threw off to a large extent their mantle of aloofness; they even carried competition into foreign countries which a few years earlier had been thought to be closed to them for the establishment of branch banks. Whether their action is wise remains yet to be seen; for in some cases it was found necessary after a few years' experience of foreign banking to form separate companies for carrying out the operations of the foreign branch banks.

Amalgamations.—Amalgamation of banks or of finance houses was, of course, no new phenomenon; it dates back to the days of the old goldsmiths, when it was not unusual for a man to break adrift from one firm of goldsmiths for the purpose of joining forces with another more enterprising competitor, and slowly, but surely, the desire to strengthen their position by absorption or alliance spread to the private banks and later to the joint stock banks. However, it was not until the period between 1891 and 1896 that we find anything in the nature of a rush to create bigger banks through the process of absorption or amalgamation. During those five years a very large number of banks in the United Kingdom ceased to be separate entities, and the policy of amalgamation was steadily pursued up to the outbreak of the World War. There was then a slight pause in what we might call the race for supremacy among the larger joint stock banks; but the great and perplexing financial problems which arose during the war kindled afresh the desire for larger and yet larger banking concerns. Gradually, the lesser banks were drawn into the pool; then important institutions which had previously been regarded as free from the temptation to amalgamate, succeeded in persuading their shareholders that the time had come to incorporate their resources with those of the premier banks, and between 1917 and 1919, scarcely a month passed without the newspapers recording the merging of one large bank into another. The earlier absorption of local banks by larger and more widely spread joint stock banks had created little more than passing interest among the public, but the policy of combination between the large joint stock banks themselves, many of them already possessed of enormous funds and branches spread over a wide area, caused a certain amount of concern in various directions, doubts being expressed as to its being to the public advantage, and in powerful business quarters the action of the banks was keenly criticized.

To investigate the matter a Treasury Committee was appointed on March 11 1918, and as the result of the deliberations of that committee the Government were recommended to pass legislation requiring that the prior approval of Government be obtained before any amalgamations were announced or carried into effect. Further, it was recommended that the approval both of the Treasury and of the Board of Trade should be obtained and that legislation should be passed requiring the two departments to set up a special statutory committee to advise them. These recommendations were carried into effect, and the new statutory committee set up; but either the objections of this body were easily met, or they found nothing to criticize in further unions, for by 1918–9 almost the entire banking strength of the country had become centred in five great combined institutions, the London Joint City & Midland Bank, Ltd., Barclay's Bank, Ltd., the London County Westminster & Parr's Bank, Ltd., the National Provincial & Union Bank of England, Ltd., and Lloyd's Bank, Ltd.

The date of the establishment of the London County Westminster & Parr's Bank, Ltd., is usually given as 1836, though as a matter of fact the London & Westminster Bank, which was the first joint stock bank established in London, was formed in March 1834. The London & County Bank was established two years later—in 1836. The actual date of the formation of Parr's Bank is not quite certain: there are records of its doing business as a private firm about 100 years ago, but as a joint stock bank it dates back no farther than 1865. Before the final amalgamation, each of the banks had obtained

a position of great importance by absorbing smaller banks, and when the London & Westminster Bank amalgamated with the London & County Banking Company, Ltd., in 1909 it was thought that the matter would rest there. Nine years later, however—in Feb. 1918, to be precise—a further addition to the strength of the combined institutions was made by the amalgamation with Parr's Bank, and the title of the bank was finally fixed as the London County Westminster & Parr's Bank. Ltd. As the bank now stands it represents six original clearing banks, viz., the London County & Westminster Bank; Jones, Lloyd & Co.; London & County Bank; Alliance Bank (subsequently changed to Parr's Bank); Fowler, Banbury & Co., and the Consolidated Bank. In Ireland the London County & Westminster Bank has affiliated with the Ulster Bank, Ltd., and it also has foreign auxiliaries in France, Belgium and Spain. The total number of banks and affiliations represented in 1921 was sixty.

The rise of the London Joint City & Midland Bank, Ltd., is no less remarkable. It was first established in 1836 as the Birmingham and Midland Bank, and although it absorbed a number of small banks from 1851 onwards, its first great step forward may be said to date from 1891, when it absorbed the Central Bank of London, Ltd., and adopted the new title of the London & Midland Bank, Ltd. Then, in 1898, it absorbed the old City Bank and again altered its name to the London City & Midland Bank, Ltd. Other amalgamations soon followed, and the principal absorptions were those of banks of such provincial fame as the Sheffield Banking Co., the North & South Wales Bank, and the Bradford Banking Co. Further additions were made by the purchase of the share capital of banks wider afield, and the bank now owns the Belfast Banking Co. and the Clydesdale Bank. The great amalgamation came, however, in 1918, when the London Joint Stock Bank, Ltd., which came into existence in July, 1836, was absorbed, and the title of the whole concern was changed to its present one of the London Joint City & Midland Bank, Ltd. As it now stands it represents what were formerly 65 banks.

Lloyd's Bank, Ltd., is remarkable for the series of amalgamations that have marked its rise to fame. The real origin of the bank can be traced back to 1765, although it was not incorporated as a joint stock bank until 1865. According to repute, it has taken over by amalgamation or absorption more banking concerns than any other similar institution. Including its affiliated institutions and foreign auxiliaries it represents a total banking strength of what were formerly 119 separate banks. Among some of the more important joint stock banks which this bank has absorbed during its career are: the Shropshire Banking Co., the Coventry & Warwickshire Banking Co., the Birmingham Joint Stock Bank, the West City & County Banking Co., Bristol & West of England Bank, and the Wilts & Dorset Banking Co. The great amalgamation came, however, when the Capital & Counties Bank, Ltd., was absorbed. The Capital & Counties Bank, as it happens, was itself established in 1834 and some six years later commenced to absorb other banks. In fact from 1877 to 1907 it acquired the business of no fewer than 26 other banks. Its career as a separate institution came to an end in the early part of 1918, when it was amalgamated with Lloyd's Bank, Ltd. Since then Lloyd's Bank has absorbed the West Yorkshire Bank and Messrs. Fox, Fowler & Co. of Somerset. It is also closely associated with the London & River Plate Bank and the National Bank of Scotland.

Barclay's Bank, Ltd., has an almost unique history. Until the year 1896 it was simply a private banking house carrying the name of Barclay & Co. Then it suddenly sprang into fame as being the originator of the amalgamations as we know them to-day. In 1896 the banking world was really taken by surprise by the announcement that Barclay & Co. had absorbed, at one sitting, 15 other private banks and had become incorporated at the same time. From that moment Barclay's progressed rapidly; the bank soon absorbed other institutions, such as the York Union Banking Co., Bolitho Williams & Co., Stamford, Spalding & Boston Bank, Ltd., and Neville, Reid & Co. The absorption of the United Counties Bank, Ltd., followed in 1916. A further large addition to its sphere of influence came in 1918 when the London & Provincial & South Western Bank was acquired, itself an amalgamation of two large joint stock banks. By this step over 250 branches in London and suburbs were added to its strength, and an interest acquired in the French subsidiary—Cox & Co. (France), Ltd. In 1919-20 Barclay's Bank extended its sphere still further by affiliations with the Union Bank of Manchester, the British Linen Bank and the Anglo-Egyptian Bank, thus giving it a total banking strength of 102 banks.

The last of the "big five" is the National Provincial & Union Bank of England, Ltd. The National Provincial was itself formed in 1833, while the Union Bank of London, though not really established until 1839, can claim through one of its constituent institutions to date back to 1688. The principal absorptions for which the combined institutions have been responsible are: the County of Stafford Bank; Isle of Wight Joint Stock Bank; London & Yorkshire Bank; Briscoe's Bank; Smith, Payne & Smith's; Union Bank of London. The Union Bank of London, it is interesting to note, itself amalgamated with Smith, Payne & Smith's, London, Smith Ellison & Co., Lincoln, Smith, Smith Bros. & Co., Hull, and Samuel Smith & Co., Derby, and the title was changed to the Union of London & Smith's Bank, Ltd., in 1902. The latter institution was amalgamated with the National Provincial Bank in 1917, the title adopted being the National Provincial Union Bank of England, Ltd. The Sheffield Banking Co. was absorbed in Dec. 1917 and the Bradford District Bank on Jan. 1 1919. A year later an affiliation was made with Cox & Co., the well-known firm of private bankers who had themselves amalgamated with Robarts, Lubbock & Co. as recently as 1914. Finally the National Provincial & Union Bank of England, Ltd., absorbed the Northamptonshire Union Bank, Ltd., in 1920. With its auxiliary bank, Lloyd's & National Provincial Foreign Bank, Ltd., this institution now represents what were formerly 63 banks.

The resources of the "big five" were, of course, very substantial before the amalgamations, and as the following table will show, there had been no diminution up to 1921:—

TOTAL CAPITAL, RESOURCES & DEPOSITS, 1913 AND 1920

	Dec. 31 1913	*Dec. 31 1920*
London County Westr. & Parr's Bk.	£143,000,000	£322,888,000
London City & Midland Bank .	101,882,000	
London Joint Stock Bank .	41,678,000	393,561,000
Lloyd's Bank, Ltd. .	98,720,000	
Capital & Counties Bank, Ltd. .	41,774,000	369,167,000
Barclay's Bank, Ltd. (June 1914) .	66,940,000	351,631,000
National Provincial Bank .		
Union of London & Smith's Bank	118,864,000	296,522,000

Just how the paid-up capital of the banks compares with that shown before the principal amalgamations took place will be seen from the following table:—

	Dec. 31 1911		*Dec. 31 1920*
London City & Midland Bk.	£3,989,238		
London Joint Stock Bank	2,970,000	£6,959,238	£10,859,800
London County & Westr. Bank	£3,500,000		
Parr's Bank, Ltd. . .	2,204,780	5,704,780	8,503,718
National Provl. Bank of Eng. . . .	£3,000,000		
Union of London & Smith's Bk.	3,554,786	6,554,786	9,309,416
Lloyd's Bank . . .	£4,208,672		
Capital & Counties Bank .	1,750,000	5,958,672	14,137,796
Barclay's Bank . . .	£3,200,000		
London & Provincial Bank	800,000		
London & S. Western Bank	1,000,000	5,000,000	11,760,811

The great upward movement in the amount of deposits held by the banks may be said to date from 1910; consequently, it will be of interest to place on record the deposits of the large banks in that year, and those at the end of 1921.

DEPOSITS OF ENGLISH BANKS AFFECTED BY THE AMALGAMATIONS

	Dec. 31 1910		*Dec. 31 1920*
London City & Midland Bk. . . .	£221,635,807		
London Joint Stock Bk.	58,456,304	£280,092,111	£371,841,968
Lloyd's Bank . .	£174,697,945		
Capital & Counties Bank . . .	58,850,522	233,548,467	345,028,984
London County & Westr. Bk. . .	£147,433,697		
Parr's Bank . .	69,227,819		
Nottingham & Notts. Bank . . .	5,723,389	222,384,905	305,380,214
Barclay's Bank . .	£129,067,901		
London & S. Western Bank . . .	38,795,039		
London & Provincial Bank . . .	36,307,726	204,170,666	327,788,370
National Provl. Bank	£112,780,401		
Union of London Bank	64,833,218		
Bradford District Bank	9,317,982	186,931,601	278,335,365

Concerning the reasons for amalgamation, little need be said. The war undoubtedly drove the leading London bankers to look for increased financial resources, in order to cope with the increased magnitude of the operations they were being called upon to finance. Fashion, the desire to out-bid other institutions, the element of self-preservation, banking evolution, the conven-

ience and gain to trade to be secured by an extension of bank areas—all such factors, however, pulled their weight in what during 1918–9 offered to be a struggle for supremacy between the leading institutions. Probably the most naive reason advanced in justification for amalgamation was that of the chairman of one of the great banks, who said that "combination must come." This was a new variant of the old *petitio principii*, "it is coming because it must come and it must come because it has come." The remark, no doubt, truly reflected a sense of the inevitability of a further stage of evolution. Even so, to the most casual observer it would seem as if the voracious appetite of the supermen in banking had at last been satiated, for so great had been the absorptions that any further extension of the activities of the "big five" would of necessity be confined to the acquisition of the relatively unimportant private or merchant banks. In a word, amalgamation had spent itself by 1920, since any further fusion of the larger institutions would probably be regarded with suspicion by the general public.

As showing how the old private institutions have gone out of existence it may be said that out of 38 private banks which were doing business in 1891, there remained only four in 1921. The latest absorption up to the middle of 1921 was the acquisition in Feb. of that year of the business of Messrs. Fox, Fowler & Co., Somerset, by Lloyd's Bank. It was interesting as marking the passing of the last country bank which had the right to issue notes. Thus closed a remarkable chapter in English banking, for under the provisions of the Bank Charter Act of 1844, the right of issue lapsed on the amalgamation with Lloyd's Bank. Further, it marked the accomplishment of one of the principal aims of the Bank Act of 1844—that of reducing the private note issues of the country, for they now ceased altogether. In 1844 this note-issuing privilege was enjoyed by 207 private banks and 72 joint stock banks, and although the Bank of England was entitled to increase the fiduciary portion of its note circulation by two-thirds of the lapsed issues, the Bank had apparently not availed itself of the full privilege, for out of the maximum issue of £8,631,000 vested in the defunct banks, the Bank of England had only increased its fiduciary circulation by £7,551,000 of the lapsed issues.

Private banking, then, has found its resting place in the archives of the things that have been, and the lesser lights of English joint stock banks are not far behind. As a matter of fact the number of English joint stock banks was reduced from 106 in 1891 to 20 in 1921, and throughout the whole of the United Kingdom, including the Bank of England and the private banks, the number of banks had fallen from 111 in 1900 to 41 in 1921.

That the resources of the banks have not suffered by this process of absorption will presently be shown, for the question of resources is an all-important one. In many respects large banks are certainly preferable, because with large resources they are in a position to make advances on a much more generous scale than the smaller concerns. Moreover, it was clearly desirable that the banks should be prepared to adapt themselves to the entirely new order of things in the financial world brought about by the war.

Actually, the public would not appear to have suffered from the fusion of the banks, for if we make a comparison of the figures of the English joint stock banks (the Scottish and Irish banks, except in a minor degree, were not much concerned with amalgamation), we find that there have been very large increases in capital and reserves; the ratio of total cash to demand liabilities has risen, and deposits show a striking increase. The ratio of paid-up capital and reserves to deposits has, however, fallen considerably, though the 1920 figures showed that the upward movement had recommenced. The following table will reveal the true position:—

English Joint Stock Banks

	Paid-up Capital and Reserves.	Deposits.	Ratio of Paid-up Capital & Reserves to Deposits	Ratio of Cash in hand, at call & notice to Liabilities.
1890	£ 67,826,000	£ 368,663,000	18·4	18
1895	69,213,000	455,561,000	15·3	19·9
1900	78,847,000	586,726,000	13·4	20·7
1905	82,010,000	627,529,000	13·1	23·6
1910	80,946,000	720,687,000	11·2	23
1913	82,068,000	809,352,000	10·1	24·3
1914	81,904,000	895,561,000	9·1	27·6
1915	81,731,000	992,555,000	8·2	22·9
1916	81,089,000	1,154,877,000	7·1	28
1917	84,475,000	1,365,297,000	6·2	28
1918	92,901,000	1,583,412,000	5·8	27·6
1919	106,273,000	1,874,184,000	5·7	21·3
1920	128,154,000	1,961,527,000	6·5	20·4

That there is no foundation for the accusation, sometimes heard, that the country had suffered from the closing of branch banks, is apparent from the fact that in 1890, when the fever for amalgamation had not taken so large a hold on the bankers, there were 104 banks in existence in England and Wales with 2,203 branches; by the end of 1920, with only 20 banks functioning, the number of branches had grown to 7,257.

In Scotland and Ireland, where the banks have preferred to strengthen their position and spheres of influence more by working arrangements with other large institutions than by actual union, the number of branches show similar expansion. Scotland in 1890 had 10 banks with 975 branches; in 1920 with only eight banks she had open 1,283 branches. Curiously enough, the number of banks operating in Ireland has not changed since 1890; there were then nine banks with 456 branches; in 1920, with the same number of banks the number of branches had exactly doubled, the total being 912. The capital and reserves of the Scottish banks in 1890 was £14,755,000; cash in hand, at call, etc., £21,427,000, against deposits of £91,610,000. By the end of 1920 the capital and reserves had grown to £17,911,000, cash in hand and money at call to £72,974,000, and deposits to £279,228,000. The capital and reserves of the Irish banks in 1890 was £10,374,000, cash in hand and money at call £9,086,000, and deposits £38,521,000. In 1920 the totals were: capital and reserves, £12,899,000; cash in hand, etc., £46,698,000; deposits, £200,441,000.

Just how great has been the extension of banking in the United Kingdom may be gauged from the following table, which shows the aggregate liabilities and assets of the banks in the United Kingdom for the pre-war period, 1913–4, and for the post-war period, 1920–1 and the respective increases involved. The figures for the Bank of England are included:—

Liabilities

	1913–4.	1920 1.	Increase.
Capital & Reserves .	£ 131,629,000	£ 179,979,000	£ 48,350,000
Undivided Profits . . .	6,705,000	8,858,000	2,153,000
Deposits . .	1,104,330,000	2,681,920,000	1,577,590,000
Acceptances .	67,547,000	109,896,000	42,349,000
Notes, Bills, etc.	54,592,000	194,836,000	140,244,000
	£1,364,803,000	£3,175,489,000	£1,810,686,000

Assets

	1913–4.	1920–1.	Increase.
Cash in hand, money at call, etc.	£ 328,559,000	£ 708,622,000	£ 380,063,000
Investments .	222,690,000	771,191,000	548,501,000
Discounts and advances .	735,104,000	1,561,337,000	826,233,000
Premises and cover for Acceptances . .	78,450,000	134,339,000	55,889,000
	£1,364,803,000	£3,175,489,000	£1,810,686,000

Increase in Deposits.—Apart from the capital and reserves, which show what, in the circumstances, must be considered for 1920–1 the satisfactory increase of £48,350,000, or 36·7% over the 1913–4 total, the first item which strikes one's attention here is the enormous increase in deposits, £1,577,590,000, or 142·8% over the 1913–4 figures. The increase in deposits was common to most, if not all, of the banks during the war period, and after. Various reasons have been assigned for it. Some bankers gravely asserted that many of the balances which went to swell their deposits represented money awaiting employment in trade, but however true that may have been during the trade slump of 1919–20, the true causes during the war were to be found in the inflation arising out of the Government's war finance; while immediately after the war, bankers were certainly too free with their advances.

Each advance had the effect of adding to the deposits of the same or of some other bank in the country, since when a person raises a loan with a bank the amount is nearly always credited to his current account. Obviously, then, an increase in bank loans and advances is concomitant with an increase in bank deposits, and as the *Bankers' Magazine* pointed out in regard to the war period "bankers were able to extend their loans in this manner because a large proportion of the inflated deposits of the war period still remained with them as additional cash, notwithstanding the large sums which they invested in Treasury Bills or were prevailed upon to lock up in the various War Loans." Undoubtedly, the increase in deposits was largely due to the immense creation of Government credits, which eventually

found their way into the pockets of producers, traders and wage-earners, and so on, to the banks. However, by the summer of 1921 the rate of increase in both deposits and current accounts showed signs of slackening, and there appeared to be little doubt that, whenever trade started to revive, the deposits of all the banks would fall rapidly.

The increase in acceptances calls for little comment; it was falling steadily in 1921, and showed a decline of over £49,000,000 between 1920 and 1921.

Credit Facilities.—Discounts and advances gave the lie direct to the critics who averred that the assistance of the bankers to trade was not what it should be. Discounts and advances together showed the very satisfactory increase of £826,233,000, or nearly 112·4%, and it proved that even if the bankers were scrutinizing more carefully the applications for discounts and advances in 1921, they were giving very active assistance to the finance of trade and industry, so far as was compatible with the precautions they were bound to consider it wise to take in the interests of their depositors.

As a matter of fact, difficulties during the transitional period from war to peace were fully appreciated as long ago as 1916, when the Board of Trade appointed a committee to investigate the question of financial facilities for trade. Another committee was also appointed for similar reasons towards the end of 1917. The terms of reference to the latter body mainly consisted of (*a*) an inquiry into the financial needs of trade immediately after the war and the respect in which these needs would differ from the needs under normal conditions, (*b*) the provision of financial facilities to meet those needs. Briefly, the committee foresaw that there would be an increased demand for credit facilities during the reconstruction period, and that the character of the demand would differ from that of normal times in that it would consist of a greater demand for loans secured upon capital goods, compared with loans secured upon consumable goods. Further, the considered opinion of the committee on financial facilities in 1917 was, that to achieve the reconstruction of trade and industry on sound financial and economic lines, it would be necessary to reëstablish a sound financial basis by means of an effective gold standard; to check any undue expansion of credit, and to take steps to reduce to more normal proportions the inflation of credit due to the war. In the banking world a movement towards this end had been gradually shaping itself, though progress up to 1921 had necessarily been slow owing to the bursting of the bubble of trade inflation, labour troubles, and world-wide depression in trade during 1920.

That there would be some difficulty in providing the extended credit facilities which, it was foreseen, would be necessary, was recognized, and to meet this difficulty the committee of 1918 recommended, among other things, an increase in the capital of the banks, and the acceptance of deposits for longer periods at fixed rates of interest. They said:—

"To enable the banks to do more in the direction of granting long trade credits, we are also of opinion that it is desirable that bankers should make more widely known their willingness to accept deposits for long periods, at fixed rates of interest. We believe that, if they were encouraged to do so, a number of depositors would be willing to deposit their money at fixed rates of interest, for periods of from one to five years, without the right of withdrawal. The removal of the liability to withdrawal would thus enable the banks to grant loans for longer periods."

To a limited extent, effect was given to these recommendations, and in 1921 the banks were all striving to meet the abnormal conditions with which they were faced.

The London branches of the colonial banks, of course, always favoured the taking of fixed deposits at a comparatively high rate of interest; but it is doubtful if the movement is destined to extend greatly among the London joint stock banks who are called upon to maintain greater liquid balances to meet withdrawals than are their colonial confrères.

One good thing towards the solution of the difficulty in providing adequate banking facilities for trade was that which arose out of the recommendations of the Board of Trade committee of 1916. As the result of the deliberations of that committee it was resolved to form a new bank to fill the gap which was said to exist between the home banks and the colonial and British-foreign banks and banking houses. The new institution was called the British Trade Corporation. Its constitution and functions were laid down by the committee to be:—

(1) To have a capital of £10,000,000. The first issue to be from £2,500,000, upon which, in the first instance, only a small amount should be paid up, but which should all be called up within a reasonable time. A further issue to be made afterwards, if possible at a premium.

(2) It should not accept deposits at call or short notice.

(3) It should only open current accounts for parties who are proposing to make use of the overseas facilities which it would afford.

(4) It should have a foreign exchange department where special facilities might be afforded for dealing with bills in foreign currency.

(5) It should open a credit department for the issue of credits to parties at home and abroad.

(6) It should enter into banking agency arrangements with existing colonial or British-foreign banks wherever they could be concluded upon reasonable terms, and where such arrangements were made, it should undertake not to set up for a specified period its own branches or agencies. It should have power to set up branches or agencies where no British-foreign bank of importance exists.

(7) It should inaugurate an information bureau.

(8) It should endeavour not to interfere in any business for which banks and banking houses now provide facilities, and it should try to promote working transactions on joint account with other banks, and should invite other banks to submit to it new transactions which, owing to length of time, magnitude or other reasons, they are not prepared to undertake alone.

(9) Where desirable, it should coöperate with the merchant and manufacturer, and possibly accept risks upon joint account.

(10) It should become a centre for syndicate operations, availing itself of the special knowledge which it will possess through its information bureau.

The British Trade Corporation was designed to fill a gap in the financial machinery of the country and to supply needs which had been long felt by trade and industry. Apart from the assistance which it might be able to render in connexion with overseas contracts, the development of existing markets and the securing of new ones, its sphere of usefulness was a large one, and properly directed, it should prove of great value to the development of British trade, finance and industry.

Foreign Banking.—As a matter of interest in the trend of British banking it may be noted that all the large joint stock banks had entered by 1921 into more or less extended foreign relations. All had proper branches devoted entirely to the financing and developing of overseas trade, and foreign exchange operations formed a much more important part of the work of all London banks than had been the case before the war.

The ramifications of some of them were by 1921 very wide; Barclay's Bank, for instance, maintained a large foreign department in London and was also affiliated with the Anglo-Egyptian Bank. Lloyd's Bank, in company with the National Provincial Bank, had also its subsidiary in France under the title of Lloyd's & National Provincial Foreign Bank, Ltd. The London County Westminster & Parr's Bank had a subsidiary bank called the London County Westminster & Parr's Foreign Bank, Ltd., and both Lloyd's and the London County Westminster & Parr's Bank were closely concerned in forming (1917) the British Italian Corporation in England and the Compagnia Italo-Britannica in Italy. The London Joint City & Midland Bank had formed no branches abroad, the view being that it was better to refrain from competing with foreign banks in their own centres; further, that besides being able to maintain amicable relations with foreign banks, a greater security was afforded to domestic depositors where the bank's activities were restricted to the home country. Some of the other banks who appeared to support this view had joined together and participated largely in the establishment of a bank known as the British Overseas Bank, which was making steady progress in the particular branch of banking for which it catered.

Altogether, then, whatever may have been the failings of the British bankers up to 1910 in the provision of means for financing overseas trade, and in attending to the foreign exchange operations of their clients, there was in 1921 no lack of facilities for clients whose business called for operations in foreign and colonial currencies.

War Services.—A word remains to be said about the rise in the investment figures, which was a noteworthy feature of the aggregate balance sheets of the banks. The increase during the decade was £548,501,000, a little over 246%, and undoubtedly a large proportion of the investments in 1921 represented the bankers' subscriptions to the various war loans in which they had participated heavily. The banks' contribution to the Victory

and Funding loans alone, it was estimated, amounted to some £111,000,000. In June 1921, however, a small decline had recently been noticeable, and it seemed probable that, as time went on, the bankers would gradually divest themselves of a large portion of Government stocks.

Great services were rendered by the banks to the Government during the war. In most of the large loans that were floated the instalments were spread over a more or less lengthy period. In determining the amounts which the banks could conveniently handle account was taken of their reserve funds, which largely consisted of their deposits with the Bank of England. In describing the actual process of assisting the Government in this loan finance, the late Sir Edward Holden compared the payments with the revolutions of a wheel. The banks were described as placing in the wheel the payments they made for their customers who had subscribed for the loans; the wheel carried these payments to the credit of the Government with the Bank of England, and the subscribers received their securities. The Government then placed in the wheel cheques in payment of commodities and services rendered for conveyance to their creditors, and the creditors in turn used the wheel to carry the cheques to the credit of their accounts in the banks, thus reëstablishing the banks' reserves and preparing them for another instalment. Another method by which the Government was helped by the banks was by the steady absorption of Treasury bills and other securities sold over the counter at the Bank of England. The banks also rendered invaluable service to the Government in making available their credit facilities with the Bank of England. "To increase their clients' ability and their own ability to invest in Government issues they would borrow from the Bank of England. These loans would increase their deposits with the Bank of England, which, as reserves, would increase their ability to grant to their own clients loans equivalent to, say, five times such deposits" (*English Public Finance*). Then in the advances to the Government on "Ways and Means" they were of important assistance. The manner in which these Ways and Means advances operated may be best described in the words of the Committee on Currency and Foreign Exchanges after the war:—

"Suppose for example, in a given week the Government require £10 million over and above receipts from taxes and loans from the public. They apply for an advance from the Bank of England, which by a book entry places the amount required to the credit of public deposits. The amount is then paid out to Government creditors, and passes, when the cheques are cleared, to the credit of their bankers in the books of the Bank of England—in other words, is transferred from 'Public' to 'Other' deposits, the effect of the whole transaction thus being to increase by £10 million the purchasing power in the hands of the public in the form of deposits in the joint stock banks and the bankers' cash at the Bank of England by the same amount. The bankers' liabilities to depositors having thus increased by £10 million and their cash reserves by an equal amount, their proportion of cash to liabilities (which was normally before the war something under 20%) is improved, with the result that they are in a position to make advances to their customers to an amount equal to four or five times the sum added to their cash reserves, or, in the absence of demand for such accommodation, to increase their investments by the difference between the cash received and the proportion they require to hold against the increase of their deposit liabilities. Since the outbreak of war it is the second procedure which has in the main been followed, the surplus cash having been used to subscribe for Treasury Bills and other Government securities. The money so subscribed has again been spent by the Government and returned in the manner described to the bankers' cash balances, the process being repeated again and again, until each £10,000,000 originally advanced by the Bank of England has created new deposits representing new purchasing power to several times that amount."

It may be noted, in connexion with the part played by the great joint stock banks in the raising of war loans, that for the first time they were made collecting agents, being so named in the prospectuses with the Bank of England.

Note Issues.—The note circulation of the English joint stock banks remained in 1921 practically unchanged at £174,000. Scottish notes, it was found, were on the increase, while Irish notes showed a considerable decline. The expansion of the paper currency of the United Kingdom may be shown as follows, the increases since 1913 being 279% for the Scottish, 206% for the Irish, and 349% for the Bank of England notes:—

(000's omitted.)

End of —	Scottish. £	Irish. £	Bank of England. £	Treasury Notes. £
1913	7,744	8,074	29,608	....
1914	9,502	10,918	36,139	38,478
1915	12,555	15,000	35,309	103,125
1916	15,461	19,112	39,676	150,144
1917	19,023	22,336	45,944	212,782
1918	25,141	30,896	70,307	323,241
1919	28,032	29,054	91,350	356,152
1920	29,363	24,718	132,851	367,626

The total issue of the Bank of England against securities is known as the Fiduciary Issue, and on June 30 1914, the amount of this issue was £18,450,000, while the Bank of England notes issued against gold coin and bullion, under the provisions of the Bank Charter Act of 1844, amounted to £38,476,000. As showing how the bank's note issue increased during the war and the period following it, it may be observed that the notes in circulation on June 1 1921 amounted to £144,093,235, as security for which the Government debt amounted to £11,015,000, other securities to £7,434,000, giving an excess circulation over the authorized issue against securities of £126,543,235, all duly covered by the deposit of gold coin and bullion in the Issue Department.

The Committee on Currency and Foreign Exchanges after the war sat in 1918 and 1919, under Lord Cunliffe's chairmanship, to consider among other things the working of the Bank Act, 1844, and the constitution and functions of the Bank of England, with a view to recommending any alterations which might appear to be necessary or desirable. Briefly, the conclusion they came to was that the principles of the Act of 1844, which upon the whole had been fully justified by experience, should be maintained, namely, that there should be a fixed fiduciary issue beyond which, subject to emergency arrangements, notes should only be issued in exchange for gold. They said in their report:—"It is noteworthy that from 1866 till the outbreak of the war (1914) no suspension of the Act was ever necessary." The Committee considered that the stringent principles of the Act had often had the effect of preventing dangerous developments, and the fact that they had had to be temporarily suspended on certain rare and exceptional occasions (and those limited to the earlier years of the Act's operation when experience of the working of the system was still immature), did not, in their opinion, invalidate this conclusion. The Committee therefore recommended that the separation of the issue and banking departments of the bank should be maintained, and that the weekly return should continue to be published in its old form. The possibility of so modifying the Act of 1844 as to make provision for the issue of emergency currency in times of acute difficulty was, however, carefully considered. They said that it might, no doubt, be sufficient to leave matters as they were prior to 1914, and to risk the possibility of the law having to be broken, subject to indemnity from Parliament, but evidently the Committee were alive to the objections that had been expressed in many quarters to this procedure. Their report states:—"We are, therefore, of opinion that the provisions of Section 3 of the Currency and Bank Notes Act, 1914, under which the Bank of England may, with the consent of the Treasury, temporarily issue notes in excess of the legal limit, should be continued in force. It should be provided by statute that Parliament should be informed forthwith of any action taken by the Treasury under this provision by means of a Treasury Minute which should be laid before both Houses. The statute should also provide that any profits derived from the excess should be surrendered by the Bank to the Exchequer." The Committee add:—"It will, of course, be necessary that the Bank Rate should be raised to, and maintained at, a figure sufficiently high to secure the earliest possible retirement of the excess issue."

The following table records the changes in the Bank of England rate from 1911 to 1920:—

	No. of changes.	Highest.	Lowest.	Average.
1911	4	4½	3	£3 9 4
1912	4	5	3	3 15 5
1913	2	5	4½	4 15 5
1914	8	10	3	4 0 9
1915	None	5	5	5 0 0
1916	1	6	5	5 9 3
1917	2	6	5	5 3 0
1918	None	5	5	5 0 0
1919	1	6	5	5 3 0
1920	1	7	6	6 14 4

A table may also be given showing (in thousands of pounds) the amounts presented through the London Bankers' Clearing House during the ten years ending in 1921:—

	Total Clearings.	Country Cheque Clearing.	Metropolitan Clearing.	On Consols Settling Days.	On Stock Exchange Account Days.
1911	14,613,877	1,221,420	796,386	678,652	2,218,700
1912	15,961,773	1,307,062	841,264	725,293	2,362,212
1913	16,436,404	1,389,481	855,648	781,892	2,082,031
1914	14,665,048	1,370,464	860,262	*515,566	†1,481,780
1915	13,407,725	1,567,571	929,064	589,654	1,025,775
1916	15,275,046	1,872,451	1,074,027	680,381	1,238,039
1917	19,121,196	2,244,190	1,177,478	881,824	1,521,191
1918	21,197,512	2,736,273	1,429,611	929,944	1,725,563
1919	28,415,382	3,386,768	1,813,029	1,296,734	2,316,366
1920	39,018,903	4,072,220	2,003,750	1,044,205	3,000,895

*Seven settlements only. †Eighteen settlements only.

The Definition of a "Bank."—One good result of the British banking amalgamations which the critics of the policy nearly always overlooked is the elimination of the weaker vessels. Even a cursory glance at the figures will convince the reader that amalgamations have given added stability to the British banks, and this cannot but be beneficial to the general public and to the commercial community. The amalgamated institutions, moreover, have been unconnected with any failures; indeed, many times they have been the means of averting bankruptcies and panics. They came through the backwash of the American financial panic of 1907-8 with a firmly established reputation for that conservatism which means strength, and just as they emerged from the black times of the Baring crisis years ago, so have they passed through the critical periods of the war years, 1914-8, with added lustre. In the monetary stringency that befell Europe on the outbreak of war, and brought many of the European bourses on the verge of disaster, it was borne upon the public what a useful function is performed by the great banks of the United Kingdom in averting banking crises and creating confidence in British financial methods.

It is true that between 1910 and 1921 there were one or two failures which brought disaster to many of the poorer folk. But these failures were not by "banks" in any proper sense of the word. One was the Charing Cross Bank, which failed in Oct. 1910. It was nothing more or less than a money-lending concern. When it closed its doors it brought ruin to a large number of poor people who, tempted by high rates of interest, had deposited their savings with the institution. Practically nothing was saved from the wreck brought about by the folly of a man, named A. W. Carpenter, who was the sole proprietor of the concern. Then there was the Birkbeck Bank, which went into liquidation on June 8 1911, mainly through its connexion with building society finance. In this instance, the consequences were not so disastrous, since, largely as the outcome of the assistance of the joint stock banks in the liquidation, the depositors were ultimately paid nearly in full. More recently, on Dec. 20 1920, history repeated itself, and the public was startled by the failure of Farrow's Bank, an institution carried on under the chairmanship of Mr. Thomas Farrow, who was sentenced to four years' penal servitude in connexion with the publication of false balance sheets of the so-called bank. The failure of this bank caused little surprise in banking circles, but, as usual, a large number of depositors of the small tradesman and artisan class were ruined by the failure. As with other institutions of this type, it was the same old story—the public lured by high rates of interest offered on current accounts and small deposits. When the bank failed it had succeeded in obtaining from the public approximately £1,458,000 in current accounts and £2,679,000 short deposits, and up to July 1921 all that it had been possible to pay to the depositors was 2s. in the £, and there seemed no probability of anyone receiving more than 5s. in the £ in final settlement.

In each case the failures gave prominence to the necessity for limiting the use of the title "bank" to institutions that really are banks. It also emphasized the necessity for the great joint stock banks to encourage the small depositor, with the result that most of them now advertise their willingness to open small deposit accounts at rates of interest consistent with prudent banking.

Immediately following the failure of the Charing Cross Bank the question was raised—"What is a bank?" and there was a demand for a definite ruling on the subject. It is curious, but true, that no Act up to 1921 had ever said what was the meaning of the word "bank," and what is still more curious, there was no decision of a Court of Law on this point. All the Bills of Exchange Act of 1882 says is—"A banker includes a body of persons whether incorporated or not, who carry on the business of banking"—a definition which has never had the slightest use in preventing scandals that have arisen in connexion with such concerns as the Charing Cross or Farrow's Bank. After the outcry in the press over the Charing Cross Bank failure in 1910 had died down, the subject was dropped, owing, it was said, to the difficulty of framing any satisfactory definition. The question was, however, raised again in 1911 on the amendment of the Money Lenders' Act, but with a similar result, and nothing useful was accomplished in the nature of preventive legislation. Then, in 1915, largely as the outcome of the banks' participation in the Government's War Loans, the question was again raised, and a small committee was got together by the late Lord Cunliffe to discuss the matter in anticipation of legislation. A report was made to the Bankers' Clearing House Committee, and the matter was continually discussed, off and on. The first definition proposed by the Clearing House Committee was this:—

"A Bank, as the term is understood in this country, may be broadly described as a firm or institution whose main business is to receive from the public monies on current account repayable on demand by cheque."

The objection to this definition, it was considered, lay in the words "main business," a general term which itself calls for explanation. It was urged that the main business of a bank is not in the receipt of money from the public, but in the relending of that money. Consequently, an alternative definition was proposed in the following terms:—

"The expression 'bank' means any persons who hold themselves out as carrying on the business of receiving from the public current account money which is to be repayable on demand by cheque, or who use the word 'bank' or any derivative of that word as part of the title or description under which they carry on business."

What, however, was considered to be even a better definition was that given by the president of the Institute of Bankers, London, Dr. Walter Leaf, in his address to the Institute of Bankers in Nov. 1920, namely:—

"The expression 'bank' means any persons who receive from the public on current account money which is to be repayable on demand by cheque, or who use the word 'bank' or any derivative of that word as part of the title under which they carry on business."

A good deal was said on the matter at the meeting in question, and most bankers present were in agreement with the president when he said that what actually was needed was a register of bankers which could be established without a hard and fast definition. Further, a tribunal should be set up with power to admit applicants or reject them from incorporation in the register on a wide view of all the circumstances of their business. This tribunal, it was argued, should be representative, not only of Government Departments, but of industry and commerce, as well as of existing banks. If such a register were set up no

one would be allowed to use the name of a bank or any derivative from it unless his name was included in the register. On all such registered banks such obligations as the publication of accounts, and so forth, would be imposed as might be thought desirable.

In the meantime the Government itself had in 1918–21 a bill under consideration which was intended to include the principal points put forward. But during 1921 it seemed to have found its resting-place in the archives of the Board of Trade.

Certainly the suggested register of bankers carries us a step farther than previous efforts have done. Sir John Paget, the eminent banking counsel, had constantly urged the necessity for reform in this matter, and in a letter to the *Journal of the Institute of Bankers* he pointed out in 1920 that the register plan offered finality where finality was sorely needed, elasticity where experience called for change. As he said, the register need not necessarily be either an Index Expurgatorius or a Book of the Righteous; it would be a true guide and friend. It would not be derogatory to bankers, for registration is both recognized and adopted in all professions. The Stock Exchange has its official list of members; the Law List is the register of counsel and solicitors, and when we come to medicine and surgery we find in the Medical Register and the General Medical Council the complete exemplar of a register and tribunal which, as Sir John Paget has argued very reasonably, might well be the pattern to be followed by the bankers. Unfortunately the blunder made by the Government in 1919 in introducing a "banks supervision" bill (for controlling amalgamation), which was so badly drafted that it had to be withdrawn, seemed to have discouraged official action.

Overseas British Banking.—The recent tendency of the English joint stock banks to take an interest in overseas banking has already been mentioned. Apparently, they had not yet in 1921 reached the point of carrying the process of amalgamation into unions with the colonial banks, though, as it happens, in 1919, *pourparlers* were taking place between representatives of Lloyd's Bank and the National Bank of India for the purchase of the shares of the latter. However, before the negotiations had reached a head the British Treasury intervened and vetoed the transaction. Nevertheless, there was an important development in India, namely the amalgamation of the three Presidency Banks, the Bank of Bengal, the Bank of Bombay, and the Bank of Madras, which, under an Act passed by the Indian Legislative Council in 1920, became united on Jan. 27 1921, and were henceforth to do business as the Imperial Bank of India. As is well known, the old Presidency Banks under the former régime were restricted in their operations; they were looked upon as semi-official institutions and as "bankers' banks." Under the Presidency Banks Act of 1876 they were prohibited from doing foreign exchange business, from borrowing or taking deposits payable outside India. They were not permitted to make loans for longer periods than six months, or to advance upon mortgage, or on immovable property, or upon promissory notes bearing less than two independent names, or upon goods, unless the goods or the title to them were deposited with the banks as security. Under the constitution of the new Imperial Bank of India, these disabilities are to a large extent removed; the bank is empowered to do most of the business which the Presidency Banks were formerly prohibited from doing. Besides acting as the bank for the Government, the Imperial Bank is permitted to have an office in London, and to rediscount bills for the Exchange Banks and other banks. It does not, however, compete with the Exchange Banks in ordinary exchange business. The appointment of the bank as the Indian Government's sole bank in India will make for economy, for it will enable the Government to abolish the expensive Reserve Treasuries in India, and the business hitherto conducted in that connexion by the Government will be done by the Imperial Bank. To render this possible, the Imperial Bank undertook to establish and to maintain within five years no fewer than 100 new branches, not less than one-fourth of which would be opened at such places as the Government might consider desirable.

It will be convenient at this point if we give particulars of the capital, etc., of the banks before the amalgamation and the position as it stood in June 1921.

Deposits in London £ 34,500
Advances in London 130,300
Cash and balances at other banks in London 130,607

The establishment of this bank is, of course, a great step forward in the banking development of India; it centralizes the operations of three large banks, but gives them larger working resources and a much larger scope. A further advantage is found in the fact that although the Government is fully represented the main working of the central concern is in the hands of private individuals. The president and vice-presidents are the representatives of the shareholders, and practically the only Government officials on the central board are the controller of the currency, not more than four nominees of the Government, and one or two managing governors appointed by the Indian Government in consultation with the central board. The first two governors were Sir N. Warren and Sir R. Aitken, who were formerly secretaries and treasurers of the Banks of Bengal and Bombay respectively, whilst the first London manager was Sir Bernard Hunter, who held formerly the position of secretary and treasurer of the Bank of Madras. Subsidiary to the central board, forming the main governing body, there were to be local boards, the latter being the existing boards of the amalgamated institutions in the three presidency towns. The central board was to function much in the same way as the Bank of England does in England. It deals with matters of general policy, "such as the movement of funds from one part of India to another, the fixation of the Indian Bank rate, which will in future be uniform for the whole of India, and the publication of the weekly statement."[1]

The local boards, under the general control of the central board, were to have a very free hand in administering the affairs of the bank, and, altogether, the whole administration was designed to carry on the work of the previous Presidency Banks with the minimum of disturbance and the maximum of efficiency.

Precisely what business the Imperial Bank was in 1921 authorized to transact was set out in the following schedule of the Imperial Bank of India Act:

The bank is authorized to carry on and transact the several kinds of business hereinafter specified, namely:—

(a) The advancing and lending money, and opening cash-credits upon the security of: (I.) stocks, funds and securities (other than immovable property) in which a trustee is authorized to invest trust money by any Act of Parliament or by any Act of the Governor-General in Council and any securities of a local Government or the Government of Ceylon.

(II.) Such securities issued by State-aided railways as have been notified by the Governor-General in Council under section 36 of the Presidency Banks Act, 1876, or may be notified by him under this Act in that behalf.

(III.) Debentures or other securities for money issued under the authority of any Act of a legislature established in British India by, or on behalf of, a district board.

[1] *Economic Journal*, vol. xxxi.

(IV.) Goods which, or the documents of title to which, are deposited with, or assigned to, the bank as security for such advances, loans or credits.

(V.) Accepted bills of exchange and promissory notes endorsed by the payees and joint and several promissory notes of two or more persons or firms unconnected with each other in general partnership.

(VI.) Fully paid shares and debentures of companies with limited liability, or immovable property or documents of title relating thereto as collateral security only where the original security is one of those specified in sub-clauses (I.) to (IV.), and if so authorized by any general or special directions of the central board, where the original security is of the kind specified in sub-clause (V.) provided that such advances and loans may be made, if the central board thinks fit, to the Secretary of State for India in Council, without any specific security.

(*b*) The selling and realization of the proceeds of sale of any such promissory notes, debentures, stock-receipts, bonds, annuities, stock, shares, securities or goods which, or the documents of title to which, have been deposited with, or assigned to, the bank as security for such advances, loans or credits, or which are held by the bank or over which the bank is entitled to any lien or charge in respect of any such loan or advance or credit or any debt or claim of the bank, and which have not been redeemed in due time in accordance with the terms and conditions (if any) of such deposit or assignment.

(*c*) The advancing and lending money to Courts of Wards upon the security of estates in their charge or under their superintendence and the realization of such advances or loans and any interest due thereon, provided that no such advance or loan shall be made without the previous sanction of the local Government concerned, and that the period for which any such advance or loan is made shall not exceed six months.

(*d*) The drawing, accepting, discounting, buying and selling of bills of exchange and other negotiable securities payable in India, or in Ceylon; and, subject to the general or special directions of the Governor-General in Council, the discounting, buying and selling of bills of exchange, payable outside India, for and from or to such banks as the Governor-General in Council may approve in that behalf.

(*e*) The investing of the funds of the bank upon any of the securities specified in sub-clauses (I.) to (III.) of clause (*a*) and converting the same into money when required, and altering, converting and transposing such investments for or into others of the investments above specified.

(*f*) The making, issuing and circulating of bank-post bills and letters of credit made payable in India, or in Ceylon, to order or otherwise than to the bearer on demand.

(*g*) The buying and selling of gold and silver whether coined or uncoined.

(*h*) The receiving of deposits and keeping cash accounts on such terms as may be agreed on.

(*i*) The acceptance of the charge of plate, jewels, title-deeds or other valuable goods on such terms as may be agreed on.

(*j*) The selling and realizing of all property, whether movable or immovable, which may in any way come into the possession of the bank in satisfaction or part satisfaction of any of its claims.

(*k*) The transacting of pecuniary agency business on commission.

(*l*) The acting as administrator, executor or trustee for the purpose of winding up estates and the acting as agent on commission in the transaction of the following kinds of business, namely:—

(I.) The buying, selling, transferring and taking charge of any securities or any shares in any public company.

(II.) The receiving of the proceeds, whether principal, interest or dividends, of any securities or shares.

(III.) The remittance of such proceeds at the risk of the principal by public or private bills of exchange, payable either in India or elsewhere.

(*m*) The drawing of bills of exchange and the granting of letters of credit payable out of India, for the use of principals for the purpose of the remittances mentioned in clause (*l*) and also for private constituents for *bona fide* personal needs.

(*n*) The buying, for the purpose of meeting such bills or letters of credit, of bills of exchange payable out of India, at any usance not exceeding six months.

(*o*) The borrowing of money in India for the purpose of the bank's business, and the giving of security for money so borrowed by pledging assets or otherwise.

(*p*) The borrowing of money in England for the purpose of bank business upon the security of assets of the bank, but not otherwise.

(*q*) Generally, the doing of all such matters and things as may be incidental or subsidiary to the transacting of the various kinds of business hereinbefore specified.

The business which the bank was not authorized to carry out or transact was set out in Part II., which stated:—

The bank shall not transact any kind of banking business other than that specified in Part I., and in particular:—

(1) It shall not make any loan or advance (*a*) for a longer period than six months, or (*b*) upon the security of stock or shares of the bank, or (*c*) save in the case of the estates specified in clause (*c*) of Part I., upon the mortgage or in any other manner upon the security of any immovable property, or the documents of title relating thereto.

(2) The bank shall not (except upon a security of the kind specified in sub-clauses (I.) to (IV.) of clause (*a*) of Part I.) discount bills for any individual or partnership-firm for an amount exceeding in the whole at any one time such sum as may be prescribed, or lend or advance in any way to any individual or partnership-firm an amount exceeding in the whole at any one time such sum as may be so prescribed.

(3) The bank shall not discount or buy, or advance and lend, or open cash-credits on the security of any negotiable instrument of any individual or partnership-firm, payable in the town or at the place where it is presented for discount, which does not carry on it the several responsibilities of at least two persons or firms unconnected with each other in general partnership.

(4) The bank shall not discount or buy, or advance and lend or open cash-credits on the security of any negotiable security having at the date of the proposed transaction a longer period to run than six months or, if drawn after sight, drawn for a longer period than six months.

Provided that nothing in this Part shall be deemed to prevent the bank from allowing any person who keeps an account with the bank to overdraw such account, without security, to such extent as may be prescribed.

The setting up of the Imperial Bank of India was an important step forward for India, and the results could not but be far-reaching. As the Government of India said in placing the scheme before the Secretary of State, the mere appearance in districts of a bank which would conduct the Government's Treasury and Public Debt business, and as to whose stability there would be no doubt, must in course of time have an appreciable effect upon the native attitude towards banking in general. Whether it would be successful in attracting large deposits from the hoards of wealth that are said to exist in India remained to be seen, but, at any rate, the other native banks would now have behind them a powerful central institution to which they could look for guidance, upon which they could rely for assistance, and which no doubt would form a necessary adjunct for the development of the various classes of banking in India, agricultural, industrial and joint stock banks. The internal trade of the country, too, could but benefit by the extension of branches which it was the declared policy of the Imperial Bank to set up.[1]

We may now turn from a consideration of this most important development in Indian banking to a similar stride forward in South Africa, in the establishment of the South African Reserve Bank, which received its charter under the South African Currency and Bank Act of 1920.

Like the Imperial Bank of India, it was to be a private institution, half the capital being subscribed by the banks doing business in the South African Union in proportion to their paid-up capital and reserve funds, and the other half provided by public subscription. If the applications from the public fell short of the 50% required, the balance would be made up from public funds. The bank was to be established first at Pretoria.

The affairs of the bank were to be managed by a Reserve Board consisting of eleven members, three being men experienced in banking and finance, and three (actively engaged in business at the time of appointment) representative of commerce, agriculture and industry. Three others were to be appointed by the Government. A governor and deputy-governor (who must be persons of banking experience) were to be appointed by the Governor-General and to hold office for five years. The person selected for the seat of the first governor was Mr. W. H. Clegg, who, prior to his appointment, was the chief accountant at the Bank of England.

Like the Federal Reserve system of America, the object of the new South African banking system is to consolidate the financial system of the country by centralizing the existing bank reserves. Further, the keeping of balances of other banks at the Reserve Bank will have the effect of making the central institution the sole custodian of the banking reserve of the country, a feature which is evidently modelled from the English system. The reserve regulations make the expansion of the note issue dependent on trade demands, and when the system is properly functioning it is expected there will be a much greater elasticity of the currency than formerly in South Africa.

For a period of 25 years from its inception the bank will have the sole right of issuing notes within the South African Union. The other banks are not ignored; they are given time to make arrangements regarding their own note issues; they will be allowed to continue the issue of their notes for 12 months, and if the Reserve Bank is then in a position to issue its own notes, they will be called upon to retire their notes gradually, and when all had lapsed (within two years,

[1] Cf. *Economic Journal*, June 1921.

one would be allowed to use the name of a bank or any derivative from it unless his name was included in the register. On all such registered banks such obligations as the publication of accounts, and so forth, would be imposed as might be thought desirable.

In the meantime the Government itself had in 1918–21 a bill under consideration which was intended to include the principal points put forward. But during 1921 it seemed to have found its resting-place in the archives of the Board of Trade.

Certainly the suggested register of bankers carries us a step farther than previous efforts have done. Sir John Paget, the eminent banking counsel, had constantly urged the necessity for reform in this matter, and in a letter to the *Journal of the Institute of Bankers* he pointed out in 1920 that the register plan offered finality where finality was sorely needed, elasticity where experience called for change. As he said, the register need not necessarily be either an Index Expurgatorius or a Book of the Righteous; it would be a true guide and friend. It would not be derogatory to bankers, for registration is both recognized and adopted in all professions. The Stock Exchange has its official list of members; the Law List is the register of counsel and solicitors, and when we come to medicine and surgery we find in the Medical Register and the General Medical Council the complete exemplar of a register and tribunal which, as Sir John Paget has argued very reasonably, might well be the pattern to be followed by the bankers. Unfortunately the blunder made by the Government in 1919 in introducing a "banks supervision" bill (for controlling amalgamation), which was so badly drafted that it had to be withdrawn, seemed to have discouraged official action.

Overseas British Banking.—The recent tendency of the English joint stock banks to take an interest in overseas banking has already been mentioned. Apparently, they had not yet in 1921 reached the point of carrying the process of amalgamation into unions with the colonial banks, though, as it happens, in 1919, *pourparlers* were taking place between representatives of Lloyd's Bank and the National Bank of India for the purchase of the shares of the latter. However, before the negotiations had reached a head the British Treasury intervened and vetoed the transaction. Nevertheless, there was an important development in India, namely the amalgamation of the three Presidency Banks, the Bank of Bengal, the Bank of Bombay, and the Bank of Madras, which, under an Act passed by the Indian Legislative Council in 1920, became united on Jan. 27 1921, and were henceforth to do business as the Imperial Bank of India. As is well known, the old Presidency Banks under the former régime were restricted in their operations; they were looked upon as semi-official institutions and as "bankers' banks." Under the Presidency Banks Act of 1876 they were prohibited from doing foreign exchange business, from borrowing or taking deposits payable outside India. They were not permitted to make loans for longer periods than six months, or to advance upon mortgage, or on immovable property, or upon promissory notes bearing less than two independent names, or upon goods, unless the goods or the title to them were deposited with the banks as security. Under the constitution of the new Imperial Bank of India, these disabilities are to a large extent removed; the bank is empowered to do most of the business which the Presidency Banks were formerly prohibited from doing. Besides acting as the bank for the Government, the Imperial Bank is permitted to have an office in London, and to rediscount bills for the Exchange Banks and other banks. It does not, however, compete with the Exchange Banks in ordinary exchange business. The appointment of the bank as the Indian Government's sole bank in India will make for economy, for it will enable the Government to abolish the expensive Reserve Treasuries in India, and the business hitherto conducted in that connexion by the Government will be done by the Imperial Bank. To render this possible, the Imperial Bank undertook to establish and to maintain within five years no fewer than 100 new branches, not less than one-fourth of which would be opened at such places as the Government might consider desirable.

It will be convenient at this point if we give particulars of the capital, etc., of the banks before the amalgamation and the position as it stood in June 1921.

RESOURCES OF THE INDIAN PRESIDENCY BANKS BEFORE THEY WERE ABSORBED BY THE IMPERIAL BANK OF INDIA

(Lakhs of rupees.)

	Capital.	Reserves.	Deposits.		Cash.
			Public.	Private.	
Bank of Bengal	200	210	388	3439	1244
Bank of Bombay	100	125	187	2650	980
Bank of Madras	75	45	124	2228	455
Total .	375	380	699	8317	2679

(Figures are in lakhs of rupees—one lakh = 100,000 rupees)

CAPITAL, ETC., OF THE IMPERIAL BANK OF INDIA, MAY 20 1921

(000's omitted.)

The above includes:

Deposits in London	£ 34,500
Advances in London	130,300
Cash and balances at other banks in London	130,607

The establishment of this bank is, of course, a great step forward in the banking development of India; it centralizes the operations of three large banks, but gives them larger working resources and a much larger scope. A further advantage is found in the fact that although the Government is fully represented the main working of the central concern is in the hands of private individuals. The president and vice-presidents are the representatives of the shareholders, and practically the only Government officials on the central board are the controller of the currency, not more than four nominees of the Government, and one or two managing governors appointed by the Indian Government in consultation with the central board. The first two governors were Sir N. Warren and Sir R. Aitken, who were formerly secretaries and treasurers of the Banks of Bengal and Bombay respectively, whilst the first London manager was Sir Bernard Hunter, who held formerly the position of secretary and treasurer of the Bank of Madras. Subsidiary to the central board, forming the main governing body, there were to be local boards, the latter being the existing boards of the amalgamated institutions in the three presidency towns. The central board was to function much in the same way as the Bank of England does in England. It deals with matters of general policy, "such as the movement of funds from one part of India to another, the fixation of the Indian Bank rate, which will in future be uniform for the whole of India, and the publication of the weekly statement."[1]

The local boards, under the general control of the central board, were to have a very free hand in administering the affairs of the bank, and, altogether, the whole administration was designed to carry on the work of the previous Presidency Banks with the minimum of disturbance and the maximum of efficiency.

Precisely what business the Imperial Bank was in 1921 authorized to transact was set out in the following schedule of the Imperial Bank of India Act:

The bank is authorized to carry on and transact the several kinds of business hereinafter specified, namely:—

(*a*) The advancing and lending money, and opening cash-credits upon the security of: (I.) stocks, funds and securities (other than immovable property) in which a trustee is authorized to invest trust money by any Act of Parliament or by any Act of the Governor-General in Council and any securities of a local Government or the Government of Ceylon.

(II.) Such securities issued by State-aided railways as have been notified by the Governor-General in Council under section 36 of the Presidency Banks Act, 1876, or may be notified by him under this Act in that behalf.

(III.) Debentures or other securities for money issued under the authority of any Act of a legislature established in British India by, or on behalf of, a district board.

[1] *Economic Journal*, vol. xxxi.

lacking the British Empire is in central banks, it certainly does not lack branch banks for the use of its nationals; what is needed is the coordination of the several systems. (W. F. S.)

II. UNITED STATES. Subsequently to the panic of 1907 and the recovery which followed, the banking system of the United States entered upon a period of prosperity and success which continued practically unbroken to the opening of the World War. The sudden outbreak of that war, 1914, caused a temporary shock not only to banking but to general business. This uncertainty, however, lasted but a few months, and was succeeded by a restoration of confidence which continued with expanding business and activity in all branches of banking down to the autumn of the year 1920. In the autumn of 1920 the development of post-war reaction in business and a violent shrinkage of prices brought severe pressure to bear upon all the elements of the banking system of the United States, but this was not sufficient to cause any dangerous shock. The period in question was one of unusual importance in American banking, not only because of the organization of the Federal Reserve system in which all national banks were compelled by law to assume membership, but also because of the fact that the strongest state banks and trust companies voluntarily entered the system during the first three years after its formation, with correspondingly broad effects upon financial organization, while the effects of the war and the expansion of American industry which accompanied the struggle greatly enlarged the activity of American banking and added to its profits.

Pre-War Period.—The years 1908–13 were characterized by a steady and consistent growth of business. In the following table, which shows the advance in the number of organized banks as well as their chief assets and liabilities, the increase of operations may be noted during the five years in question, and may be compared with the advance during the war period:—

PRINCIPAL ITEMS OF RESOURCES AND LIABILITIES OF NATIONAL, STATE, SAVINGS, PRIVATE BANKS, LOAN AND TRUST COMPANIES FROM 1900 TO 1920. Compiled from reports obtained by the Comptroller of the Currency.

(In millions of dollars)

In order to show the relative position occupied by the national banks, the following tabular comparison, relating to national institutions only, is presented. It will be understood that while the state banks and trust companies included in their number the bulk of the investment institutions of the nation, the commercial banking assets were predominantly held by the national banks.

The period 1908–13 was not, however, notable for any far-reaching changes in method or organization; provisions which had been enacted in the Aldrich-Vreeland law of May 30 1908 for the formation of national currency associations (*see* FEDERAL RESERVE BANKING SYSTEM) remaining practically a dead letter. There being no immediate or urgent necessity for the creation of national currency associations, since no disturbance in business conditions seemed to be imminent, the national banks made no effort to form them.

GROWTH OF NATIONAL BANKS BY FIVE-YEAR PERIODS

(In thousands of dollars)

	No. of banks.	Total deposits.	Loans and discounts.[1]	Reserve held.	Excess reserve.
Sept. 5 1900	3,871	3,699,804	2,686,760	983,333[2]	299,208
Aug. 25 1905	5,757	5,508,643	3,998,509	1,294,298[2]	322,170
Sept. 1 1910	7,173	7,140,836	5,467,161	1,573,522[3]	313,415
Sept. 2 1915	7,613	9,229,516	6,756,680	1,969,398[3]	868,756
Sept. 8 1920	8,093	16,751,956	13,706,066	1,232,039[4]	38,092

	No. of banks.	Capital.	Surplus and undivided profits.	Circulation	Total resources.[1]
Sept. 5 1900	3,871	630,299	389,469	283,949	5,048,138
Aug. 25 1905	5,757	799,870	620,294	468,980	7,472,351
Sept. 1 1910	7,173	1,002,735	874,038	674,822	9,826,181
Sept. 2 1915	7,613	1,068,864	1,022,596	718,496	12,267,090
Sept. 8 1920	8,093	1,248,271	1,456,067	693,270	21,885,480

[1] Includes rediscounts.

[2] Includes cash in vault and due from reserve agents.

[3] Cash in vault, $812,609,000; due from Federal Reserve banks, $315,409,000; due from approved reserve agents, $811,380,000.

[4] Lawful reserve with Federal Reserve bank. In addition, national banks held $471,546,000 cash in vault and $1,917,438,000 due from other banks including items with Federal Reserve banks in process of collection.

During the years in question the National Monetary Commission, appointed in accordance with the provisions of the Aldrich-Vreeland law, was prosecuting its investigations into existing conditions, but these investigations were academic up to 1912, while even in the latter year the bill for banking reorganization proposed by the National Monetary Commission (the "Aldrich Bill") had small chance of success so that at no time prior to 1913 was there a serious prospect of fundamental change in legislation. The adoption of the Federal Reserve Act in the latter year greatly altered the conditions under which the national banking system, and indeed the whole banking system of the United States, was operating, but it did not produce any direct or immediate effect upon the methods or position of the banks themselves until a much later date. Indeed, the Federal Reserve Act itself did not come into practical operation until nearly a year subsequently to its passage, the reserve banks being organized in Nov. 1914. During the prewar years, however, the problems of the national banking system which had already been recognized had been growing more and

more obvious. Prominent among these was the insufficiency of the note currency, which continued to be issued solely upon the security of national bonds. In the accompanying table the note issues of the national banks during the years in question may be traced:—

YEARLY INCREASE OR DECREASE IN NATIONAL BANK CIRCULATION FROM 1900 TO 1920

	Issued	Retired	Increase	Decrease
1900	$101,645,393	$16,537,068	$85,108,325	
1901	123,100,200	15,951,527	107,148,673	
1902	42,620,682	21,868,006	20,752,676	
1903	68,177,467	28,474,958	39,702,509	
1904	69,532,176	31,930,783	37,601,393	
1905	90,753,284	22,732,060	68,021,224	
1906	84,085,200	25,055,739	59,029,521

Total	$735,612,324
Less[1]	3,062,695
Total	$732,549,629

[1] Notes redeemed but not assorted by denominations.

The figures show a practically stationary condition of the circulation. They cannot, however, throw light upon the increasing volume of demand for currency, which during those years was growing at a rapid rate. Only through an enlarged use of cheques and other credit substitutes or through additions to the basic monetary circulation itself was it possible for the United States to add to its circulating medium. Another factor which had assumed very great importance during the preliminary period referred to, was the growth of trust companies, involving as it did sharp competition with national banks. Subsequently to the year 1890 there had been a rapid development of trust companies in many parts of the United States as well as extension and improvement of legislation affecting them. In some states the trust companies, either through local restriction or as the result of custom, still confined themselves to fiduciary business, but under the laws of most commonwealths they had taken on banking functions, and in some they had developed the latter with so much success as to make their preliminary or nominal purposes largely secondary. Due to the fact that trust company laws were usually much less restrictive than those which controlled the operation either of national banks or of state banks, both of the latter classes of institutions were feeling the competition of the trust companies with considerable severity. The table on the next page shows the relative positions of different classes of banks in 1920 and the increase in the number of trust companies and savings banks during recent years.

Savings banks' development during this period is shown in the following figures:—

Year	Banks	Depositors	Deposits
1900	1,002	6,107,083	$2,449,547,885
1901	1,007	6,358,723	2,597,094,580
1902	1,036	6,666,672	2,750,177,290
1903	1,078	7,035,228	2,935,204,845
1904	1,157	7,305,443	3,060,178,611
1905	1,237	7,696,229	3,261,236,119
1906	1,319	8,027,192	3,482,137,198
1907	1,415	8,588,811	3,690,078,945
1908	1,453	8,705,848	3,660,553,945
1909	1,703	8,831,863	3,713,405,710
1910	1,759	9,142,908	4,070,486,246
1911	1,884	9,794,647	4,212,583,598
1912	1,922	10,010,304	4,451,818,522
1913	1,978	10,766,936	4,727,403,950
1914[2]	2,100	11,109,499	4,936,591,849
1915	2,159	11,285,755	4,997,706,013
	622	8,592,271	4,186,976,600
1916	1,242	2,556,121	901,610,694[3]
	622	8,935,055	4,422,489,384
1917	1,185	2,431,958	995,532,890
	625	9,011,464	4,422,096,393
1918	1,194	2,368,089	1,049,483,555[3]
	622	8,948,808	4,751,113,000[3]
1919	1,087	2,486,073	1,151,464,000[3]
	620	9,445,327	5,186,845,000[3]
1920	1,087	1,982,229	1,349,625,000[3]

[2] In the assembling of data in relation to savings banks the classification of banks as made by the State banking departments is closely followed, in consequence of which a number of so-called State savings banks, formerly treated by the Comptroller's office as savings banks, are now regarded as commercial banks, and the returns therefrom are combined with the latter, which accounts for the relatively small amount of deposits reported for stock savings banks since 1915.
[3] Dividends unpaid not included.

The number of trust companies and information with reference to the principal items of assets and liabilities on or about June 30 of each year since 1914 are shown in the following table:—

	Number	(In millions of dollars.)					
		Loans *	Investments	Capital	Surplus & Profits	All Deposits	Aggregate Resources
1914	1,564	2,905.7	1,261.3	462.2	564.4	4,289.1	5,489.5
1915	1,664	3,048.6	1,349.6	476.8	577.4	4,604.0	5,873.1
1916	1,606	3,704.3	1,605.4	475.8	605.5	5,732.4	7,028.2
1917	1,608	4,311.7	1,789.7	505.5	641.8	6,413.1	7,899.8
1918	1,669	4,403.8	2,115.6	525.2	646.9	6,493.3	8,317.4
1919	1,377	4,091.0	2,069.9	450.4	588.6	6,157.2	7,959.9
1920	1,408	4,601.5	1,902.1	475.7	612.1	6,518.0	8,320.0

* Includes overdrafts.

While commercial banks, both national and state, had from time to time considered the question of seeking permission to exercise fiduciary functions, the problem had never assumed any considerable importance until the Federal Reserve Act was brought up for consideration. Their policy had been directed towards enforcing a limitation or restriction of the banking functions of trust companies, both in the states where local legislation had not made much direct concession to trust company activity, and in those where a beginning had already been made in extending to them banking powers, rather than to competing with them. One demand which had been made with entire justice by the national banks had been that in so far as they exercised actual banking functions and became liable for demand deposits, the trust companies should be required to keep a proportion of reserve equal to that required of the banks with which they were competing. Something had been done in the direction of applying such a requirement, but state laws were still in an unsatisfactory condition.

The Opening of the World War.—The year 1914 had opened prosperously for the banks of the country, business being practically normal and employment at least up to the average, while agricultural conditions were satisfactory. The sudden advent of war in Europe at the end of July, however, necessarily subjected the banks to a very severe shock. Due to the seasonal character of American exportations of agricultural products

RESOURCES AND LIABILITIES OF 22,109 STATE, SAVINGS, AND PRIVATE BANKS AND LOAN & TRUST COMPANIES, JUNE 30, 1920

and of many of the importations of manufactures, it had become customary in past years for English banks to hold claims upon American institutions which gradually accumulated each year up to the opening of the autumn season, when the movement of crops to foreign countries provided funds which were used for the cancellation of these balances. At the opening of the war it was supposed that in trade with England such balances against American banks amounted to something like $500,000,000. One phase of Great Britain's economic policy upon the outbreak of war was to call in the balances due to her in foreign countries and generally to cut off trade relations that might subject her credit structure to fresh demands. At the same time the presence of German war-vessels in the Atlantic made it uncertain how long a time must elapse before the movement of goods to and from Europe would be resumed upon a normal basis. The export trade of the United States was thus seriously checked at the same time that extensions of credit by British banks were practically suspended. One immediate effect of this situation was to cause a large exportation of gold from the United States, while the shipment of goods was first reduced, and at last temporarily suspended. These two factors caused serious disturbances in the eastern part of the country and produced a general lack of confidence, while at the same time they tended to depress the prices of American staples. Cotton was affected with particular seriousness, its price declining during the autumn to a point as low as five cents per pound as against a figure, then regarded as normal or satisfactory, of 12 or 13 cents in the early part of the year. In consequence of this stagnation of export trade, there was a somewhat corresponding shock to domestic business, a resulting difficulty in making collections, and eventually a withdrawal of funds from banks not only for export of specie, but also for the purpose of domestic hoarding. Congress, which was then in session, hastened to amend the Aldrich-Vreeland Act of 1908, the measure thus adopted taking effect on Aug. 4 1914. Under the terms of this amendatory measure the issue of emergency currency was permitted under more liberal conditions than before. It would have been much better if the Federal Reserve Act, which was passed during the preceding Dec., had been brought into operation, but as a matter of fact reserve banks did not get under way until Nov. 1914. The action of Congress in passing the emergency currency law was, therefore, necessary in order to provide an immediate means of furnishing funds for the payment of depositors. The currency thus provided for under the new law was accordingly issued and eventually rose to a peak point of about $430,000,000. This served to take the place of gold which was then moving out of the country, the total gold exports during 1914 amounting to approximately $223,000,000. Meanwhile the Federal Reserve Board had been organized in accordance with the terms of the Federal Reserve Act on Aug. 10 1914, and was immediately confronted by the great losses of gold which were being incurred by the banks in order to satisfy the demands of British creditors. In the belief that much of this withdrawal of gold was due to a lack of combined action on the part of the American banks, the board supervised the formation of what became known as the "international exchange fund," or "gold pool," which was in effect an agreement among American banks to provide a total of $100,000,000 of gold for export (or gold exchange), permitting any bank that might be drawn upon to supply itself from the common stock by depositing therein satisfactory funds in other forms. This measure was effective in restoring confidence while at the same time the first fear and uncertainty that had resulted from war conditions began rapidly to disappear; German vessels were soon driven from the North Atlantic and the movement of products from the United States to Europe was resumed upon a limited scale. The urgency of demands for cash declined and the banks (which had begun the issue of clearing-house certificates on Aug. 3) were able to retire their obligations on Dec. 1, although the Stock Exchange (which had been closed on July 31) was not reopened until later. Thus the banks of the country passed through the dangerous early stages of the war partly by exercising their own latent power and partly in consequence of the aid which had been extended to them through Congressional enactment and through coöperative effort under the leadership of the Federal Reserve Board.

The Banks and the Federal Reserve System.—The projected text of the Federal Reserve Act had been made public in June 1913, and had served as a basis for discussion from that date up to the passage of the Act on Dec. 23 of the same year. It may fairly be said that practically all of the banks of the country were opposed to it—the national banks primarily because it made membership in the system compulsory; the other banks because they feared that great changes and innovations in business would result from the new system. After the adoption of the Federal Reserve Act the question whether or not to enter the system became acute with national banks since the law had provided that a failure of any national bank to enter the system would mean the necessity of surrendering its charter and transferring itself to a state banking system, through reincorporation. Accordingly during the early part of the year 1914 there was constant discussion of the wisdom or the unwisdom of declining to accept membership. The result was a

practically unanimous determination to take stock in the new Federal Reserve banks. The principal points at which the new Act immediately touched the national banks were in connexion with the contribution of capital and the transfer of their reserves. In the course of the discussion of the Federal Reserve Act there had been an effort on the part of the national banks (especially after membership in the system had been made compulsory) to reduce the required amount of contribution to the capital stock of the Federal Reserve banks to as low a level as possible. It was eventually fixed at 3% of the capital and surplus of each national bank, so that when the banks eventually entered the system (as all except some eight or ten finally did) they were obliged to pay in only about $50,000,000. In the same way they had endeavoured to avoid the necessity of transferring any part of their reserves to the Federal Reserve banks, except as they might elect, but had not entirely succeeded, although a three-year period was finally provided during which the transfers might be made in instalments, and only part of the reserves was even eventually to be transferred. At the outset the banks paid over to the Federal Reserve banks only about $18,000,000 of capital and $227,000,000 of reserve deposits. These payments were made during the month of Nov. 1914 and, as just shown, were only about $245,000,000 in all, so that the burden of establishing the reserve system was not a particularly heavy one. Indeed, with the reduction in reserve requirements which had been made in the Federal Reserve Act (central reserve city banks being cut from 25% of reserve deposits to 18%, reserve city banks from 25% to 15% and country banks from 15% to 12%), the banks were in much better condition to take care of the needs of their customers than they were before the organization of the reserve system, even without any recourse to rediscounting. In view of the fact that European demands for American goods were considerably reduced during the first months of the war, so that industry was temporarily checked and domestic prices were lowered, bank resources were more than adequate to the needs of customers. Later as the requirements of European countries became heavier and export shipments from the United States were increased, the banks entered upon a period of unusual prosperity, and the difficulty in earning dividends which they had experienced during 1915 disappeared. Credit in fact became comparatively safe, not only on account of the rapidly rising prices which greatly reduced the danger of business failure, but also because of the fact that many of the large purchases of goods in the United States made for European account were practically guaranteed by foreign Governments which at that time were in a relatively strong financial condition. The number of banks accordingly increased steadily and the capital and surplus even more markedly, as may be seen from the tables already given. What has been said in this section is intended to apply directly to the case of the national banks but holds equally true of state institutions (both banks and trust companies). All went through a somewhat parallel course of development, while the high wages and steady employment which were due to very large European purchases of goods provided a strong basis for the growth of savings. Savings deposits accordingly advanced decidedly in amount. For the same reason which enabled national banks to refrain from re-discounting, state banks and trust companies were relieved of any urgent necessity to enter the Federal Reserve system. The system accordingly extended but little credit to its members up to the end of 1916, while it enlarged its membership very little outside of the national banks themselves.

The War Period.—An entirely different situation came into existence immediately upon the entry of the United States into the World War in April 1917. There had already been some growth of re-discounting during the earlier months of that year, and Congress after the opening of the war, June 1917, amended the Federal Reserve Act. By the terms of this new law all reserves of national banks were to be carried in Federal Reserve banks and nothing held in vault was to be counted as reserves, it being felt that such action was practically essential in order to concentrate the banking power of the country, to enlarge the lending power of the reserve banks and to relieve the members of the necessity of carrying coin in vault. At the same time effort was made to discourage the payment of coin or legal-tender money to depositors, so that the banks soon passed to what was really a paper basis. The continued importations of gold strengthened the reserve bank holdings, so that there was at all times far more gold in the country than before the war. The net increase in gold holdings was fully $1,000,000,000, but gold coin had practically disappeared from common use. Congress had also provided, in the Act already referred to, for membership of state banks in the Federal system under conditions which permitted them to withdraw whenever so disposed by giving six months' notice. Partly because of this assurance of ability to retire and partly because of a feeling that the advent of war would naturally subject all banks to severe stress, while at the same time it was regarded as a matter of patriotism to render such aid to the Government as they could, a large number of institutions entered the system. These accretions to membership continued rapidly during the years 1917–8 and resulted eventually in the admission of about 1,200 state institutions. The movement into the system had a rather important effect upon the banks and trust companies that joined. They were compelled as a condition of membership to maintain reserves equal to those of the member banks already in the system, so that a process of standardizing reserves was effectively carried forward. During the years 1915–8 there had been extensive changes in state banking legislation. These changes had provided more nearly uniform reserve requirements, besides authorizing the local state banks to become members of the reserve institutions if they felt so disposed. In consequence even those banks which did not become members were in some measure adjusted to the banking situation by being subjected to more uniform requirements. A somewhat similar process was also going on in the matter of types of bank paper, the new legislation both of Congress and of the states being intended to standardize these types. Thus the United States emerged from the war with a much more harmonious and uniform system of banking legislation than it had ever before possessed.

Change in Holdings.—The effect of the war was, however, of a very far-reaching character in its relation to the portfolios or paper holdings of the banks of the country. The method of financing the war which was chiefly resorted to by the Treasury involved heavy taxation, but it was some time before the new taxes could yield any returns and the Federal Government never obtained from that source more than about one-third of its total outlay. The other two-thirds were obtained from the banks and the public by borrowing. The public was encouraged to save and to use its savings in the purchase of Liberty Bonds, but a very large proportion of the bonds sold to the public had to be carried in part at least by means of loans obtained at banks upon paper collateralled by Government obligations. This was true of all classes of banks, both national and state, as well as of the trust companies, while the latter and the savings banks were also urged to purchase and hold as many Liberty Bonds as they could. In these ways the investments of the banks and their commercial portfolios came to consist very largely of paper collateralled by Government obligations. This was true not only of the paper which represented subscriptions to bonds, but also of paper which took the place of ordinary commercial borrowings. Due to the fact that many business men preferred to borrow on their own notes collateralled by Government bonds in order to get the lower rates of interest made by the banks on such notes, paper of this kind rapidly displaced ordinary evidences of indebtedness. This state of things continued until some time after the close of the war, a modification occurring in the autumn of 1919 and continuing to grow more pronounced thereafter.

New Functions of National Banks.—Prior to the adoption of the Federal Reserve Act national banks had not been allowed to perform so-called fiduciary functions, including those of acting

as guardian or trustee, registrar, fiscal agent, administrator and others. These functions had been exclusively performed by trust companies, most states following the example of the National Bank Act and drawing a sharp line of distinction between their own state banks and their trust companies. The Federal Reserve Act authorized the assumption of fiduciary powers by national banks upon permission of the Federal Reserve Board. Such permission when granted by the Board was promptly questioned in the courts, but was upheld by the Supreme Court of the United States. This decision led to an extension of the scope of the fiduciary functions so that national banks were shortly placed upon a basis of competitive equality with trust companies. The situation led various states to modify their laws in such a way as to permit state banks to take on fiduciary functions likewise. Thus the distinction which had previously existed between national banks, commercial state banks, and trust companies was gradually wiped out. By the end of 1920 about 1,200 national banks had been granted permission to exercise trust functions. The time has not yet been sufficiently long to permit an accurate judgment of the effect of these changes upon the general banking situation, the full exercise of fiduciary functions being usually a process of comparatively slow development.

Organizing for Foreign Trade.—One of the principal defects of the old national banking system was that it did not function well in connexion with foreign trade. Neither national nor state banks had been in the habit of using bankers' acceptances, which had become the standard basis of foreign business in Great Britain. This defect was remedied in the Federal Reserve Act, which authorized the making of acceptances by national banks up to an amount equal to 100% of the capital and surplus of the accepting bank (50% in the original Act confined to foreign trade, but later amended to 100% of which not to exceed 50% might be domestic acceptances). Several of the states in which banking had assumed the greatest development made a similar change in their legislation at about the same time, so that at the opening of the World War, with its great impetus to American foreign trade, the banking system, both national and state, was in position to finance business on the acceptance plan. It was seen, however, in the formulation of the Federal Reserve Act that in order to develop foreign banking successfully the use of the branch system would be necessary. Branch banking had never been permitted in the United States under the National Bank Act, and although it sporadically existed under various state laws such systems were only local and not particularly successful. It may broadly be said, therefore, that there had been no development of the branch bank principle prior to 1913. Although at one time it was proposed to insert in the Federal Reserve Act permission to establish domestic branches of national banks, and although the Act gave to Federal Reserve banks power to establish branches within their own districts and at their own discretion, it withheld from national banks power to create domestic branches. It, however, did vest them under certain conditions with the power to establish branches abroad. This power was used by only one or two of the larger national banks, and early in 1915 the demand for action which would allow national banks to subscribe to the stock of foreign trade banks to be jointly owned by them became very strong. Accordingly Congress in 1915 modified the Federal Reserve Act to the extent of permitting the organization of foreign trade banks. The plan, however, did not meet with much favour and few such banks were organized. Those which were brought into existence did a fairly successful business, but not enough were established to give the plan a commanding place in American financial life. The subject, however, of financing foreign trade was unavoidably thrown into the background by the advent of the war and the conditions growing out of it. Foreign countries financed their purchases of American goods upon what was practically a cash basis prior to the time that the United States itself entered the war and after that date practically the whole export trade of the United States was financed upon the basis of Government credits for which the U.S. Treasury furnished the means. The result was to make the whole foreign banking question far less urgent or immediate than it would otherwise have been. Not until the war had closed, and indeed, not for some considerable time after, did the subject receive discussion. Such discussion, however, became general about the middle of 1919, and at that time it seemed to the Federal Reserve Board that a plan of action modelled upon the British investment trust might serve as a basis for the general long-term financing of American exports. This export financing was regarded as essentially a problem which involved the shipment of goods upon long-term credit, it being recognized that much time must elapse before foreign countries could send to the United States enough goods to keep their American trade in current balance. Accordingly the so-called Edge Act was passed Oct. 1919. It and the regulations subsequently issued by the Federal Reserve Board provided for the establishment of foreign trade financing corporations of two classes, the one vested with very large powers of acceptance and really differing in no essential way from the foreign trade banks already referred to, except that the stock of the Edge Act corporations might be held by individuals or commercial establishments and not exclusively by banks. The other type of corporation was to be organized for the purpose of providing credit in the export trade, the securities and evidences of indebtedness which it received being employed as a basis upon which debentures or bonds would be issued and offered to the public, thereby restoring to the corporation issuing them the funds which it required, for still further dealings and advances of the same kind. At first but little interest was shown in the idea of such corporations. Prior to the close of 1920 only one had been actually organized although several were under consideration, and early in 1921 the formation of two additional enterprises of the same sort was announced. The most important of the early undertakings under the Edge enactment was a corporation projected by the committee representing the American Bankers' Association, whose capital was to be $100,000,000 and whose stock was offered to the public early in the year 1921. The Edge Act may be summarized in the statement that it was in effect a plan to provide for the financing of foreign trade apart from domestic banking operations, and with a very much greater latitude in respect to the granting of credit than could properly be allowed to domestic institutions.

Growth of a Discount Market.—The use of the acceptance function to which reference has already been made progressed comparatively slowly during the early years of the Federal Reserve system, being retarded by the various disturbing conditions attendant upon the war. The expansion of the acceptance proceeded most rapidly and reliably in connexion with foreign trade, where this type of paper speedily assumed a position of some importance. Its growth was, however, greatly restricted as a result of the lack of branch banks maintained by American institutions in foreign countries. At the close of 1920 it was estimated by the Federal Reserve Board that the total amount of acceptances made by member banks of the system and then outstanding was probably a little under $650,000,000. The bulk of these acceptances had been made by a comparatively small number of acceptance-issuing institutions located for the most part at points whose interest carried them in considerable measure into the export trade. Some interior banks had attempted to develop the domestic acceptance, but with no great success, while the commercial, or trade, acceptance, or "domestic bill" as known in other countries, had shown but slight signs of assuming importance. This was partly due to the existence of the well-known system of offering cash discounts which, if it did not originate in the United States had attained by far its greatest development there. Under the cash discount system, while invoice prices were strictly maintained, a second or reduced invoice price was offered to those who were able to make an immediate or "cash" payment within a specified number of days from the date of the invoice, while to those who preferred to enjoy the full period of credit the full face value of the

practically unanimous determination to take stock in the new Federal Reserve banks. The principal points at which the new Act immediately touched the national banks were in connexion with the contribution of capital and the transfer of their reserves. In the course of the discussion of the Federal Reserve Act there had been an effort on the part of the national banks (especially after membership in the system had been made compulsory) to reduce the required amount of contribution to the capital stock of the Federal Reserve banks to as low a level as possible. It was eventually fixed at 3% of the capital and surplus of each national bank, so that when the banks eventually entered the system (as all except some eight or ten finally did) they were obliged to pay in only about $50,000,000. In the same way they had endeavoured to avoid the necessity of transferring any part of their reserves to the Federal Reserve banks, except as they might elect, but had not entirely succeeded, although a three-year period was finally provided during which the transfers might be made in instalments, and only part of the reserves was even eventually to be transferred. At the outset the banks paid over to the Federal Reserve banks only about $18,000,000 of capital and $227,000,000 of reserve deposits. These payments were made during the month of Nov. 1914 and, as just shown, were only about $245,000,000 in all, so that the burden of establishing the reserve system was not a particularly heavy one. Indeed, with the reduction in reserve requirements which had been made in the Federal Reserve Act (central reserve city banks being cut from 25% of reserve deposits to 18%, reserve city banks from 25% to 15% and country banks from 15% to 12%), the banks were in much better condition to take care of the needs of their customers than they were before the organization of the reserve system, even without any recourse to rediscounting. In view of the fact that European demands for American goods were considerably reduced during the first months of the war, so that industry was temporarily checked and domestic prices were lowered, bank resources were more than adequate to the needs of customers. Later as the requirements of European countries became heavier and export shipments from the United States were increased, the banks entered upon a period of unusual prosperity, and the difficulty in earning dividends which they had experienced during 1915 disappeared. Credit in fact became comparatively safe, not only on account of the rapidly rising prices which greatly reduced the danger of business failure, but also because of the fact that many of the large purchases of goods in the United States made for European account were practically guaranteed by foreign Governments which at that time were in a relatively strong financial condition. The number of banks accordingly increased steadily and the capital and surplus even more markedly, as may be seen from the tables already given. What has been said in this section is intended to apply directly to the case of the national banks but holds equally true of state institutions (both banks and trust companies). All went through a somewhat parallel course of development, while the high wages and steady employment which were due to very large European purchases of goods provided a strong basis for the growth of savings. Savings deposits accordingly advanced decidedly in amount. For the same reason which enabled national banks to refrain from re-discounting, state banks and trust companies were relieved of any urgent necessity to enter the Federal Reserve system. The system accordingly extended but little credit to its members up to the end of 1916, while it enlarged its membership very little outside of the national banks themselves.

The War Period.—An entirely different situation came into existence immediately upon the entry of the United States into the World War in April 1917. There had already been some growth of re-discounting during the earlier months of that year, and Congress after the opening of the war, June 1917, amended the Federal Reserve Act. By the terms of this new law all reserves of national banks were to be carried in Federal Reserve banks and nothing held in vault was to be counted as reserves, it being felt that such action was practically essential in order to concentrate the banking power of the country, to enlarge the lending power of the reserve banks and to relieve the members of the necessity of carrying coin in vault. At the same time effort was made to discourage the payment of coin or legal-tender money to depositors, so that the banks soon passed to what was really a paper basis. The continued importations of gold strengthened the reserve bank holdings, so that there was at all times far more gold in the country than before the war. The net increase in gold holdings was fully $1,000,000,000, but gold coin had practically disappeared from common use. Congress had also provided, in the Act already referred to, for membership of state banks in the Federal system under conditions which permitted them to withdraw whenever so disposed by giving six months' notice. Partly because of this assurance of ability to retire and partly because of a feeling that the advent of war would naturally subject all banks to severe stress, while at the same time it was regarded as a matter of patriotism to render such aid to the Government as they could, a large number of institutions entered the system. These accretions to membership continued rapidly during the years 1917-8 and resulted eventually in the admission of about 1,200 state institutions. The movement into the system had a rather important effect upon the banks and trust companies that joined. They were compelled as a condition of membership to maintain reserves equal to those of the member banks already in the system, so that a process of standardizing reserves was effectively carried forward. During the years 1915-8 there had been extensive changes in state banking legislation. These changes had provided more nearly uniform reserve requirements, besides authorizing the local state banks to become members of the reserve institutions if they felt so disposed. In consequence even those banks which did not become members were in some measure adjusted to the banking situation by being subjected to more uniform requirements. A somewhat similar process was also going on in the matter of types of bank paper, the new legislation both of Congress and of the states being intended to standardize these types. Thus the United States emerged from the war with a much more harmonious and uniform system of banking legislation than it had ever before possessed.

Change in Holdings.—The effect of the war was, however, of a very far-reaching character in its relation to the portfolios or paper holdings of the banks of the country. The method of financing the war which was chiefly resorted to by the Treasury involved heavy taxation, but it was some time before the new taxes could yield any returns and the Federal Government never obtained from that source more than about one-third of its total outlay. The other two-thirds were obtained from the banks and the public by borrowing. The public was encouraged to save and to use its savings in the purchase of Liberty Bonds, but a very large proportion of the bonds sold to the public had to be carried in part at least by means of loans obtained at banks upon paper collateralled by Government obligations. This was true of all classes of banks, both national and state, as well as of the trust companies, while the latter and the savings banks were also urged to purchase and hold as many Liberty Bonds as they could. In these ways the investments of the banks and their commercial portfolios came to consist very largely of paper collateralled by Government obligations. This was true not only of the paper which represented subscriptions to bonds, but also of paper which took the place of ordinary commercial borrowings. Due to the fact that many business men preferred to borrow on their own notes collateralled by Government bonds in order to get the lower rates of interest made by the banks on such notes, paper of this kind rapidly displaced ordinary evidences of indebtedness. This state of things continued until some time after the close of the war, a modification occurring in the autumn of 1919 and continuing to grow more pronounced thereafter.

New Functions of National Banks.—Prior to the adoption of the Federal Reserve Act national banks had not been allowed to perform so-called fiduciary functions, including those of acting

Fair (1912); and the fine Hebridean Symphony (1916) for the publication of which the Carnegie Trust made themselves responsible. His great choral symphonies, for instance, *Atalanta*, a colossal work for unaccompanied choirs, occupying about 45 minutes in performance, and its companion, *Vanity of Vanities* (1914), are remarkable examples of his work. Bantock was largely instrumental in establishing the Birmingham competition festivals in 1912 and in increasing their efficiency.

BARCLAY, FLORENCE LOUISA (1862–1921), English novelist, was born at Limpsfield, Surrey, Dec. 2 1862, the daughter of the Rev. S. Charlesworth, rector of the parish, and niece of Maria Louisa Charlesworth, author of *Ministering Children*. On March 10 1881 she married the Rev. Charles Barclay, vicar of Little Amwell, Herts. Her first novel, *The Wheels of Time*, appeared in 1908, but she is best known by its successor, *The Rosary* (1909), which reached a circulation of close on a million copies and was translated into many languages. The combination of religious feeling and strong love interest which characterized most of her novels appealed to a very wide public, and she enjoyed for some years an immense popularity, the total circulation of her books exceeding 2,500,000. Later novels included *The Mistress of Shenstone* (1910), specially filmed in America; *The Following of the Star* (1911); *The Broken Halo* (1913); *In Hoc Vince* (1915); *Returned Empty* (1920). She died at Limpsfield March 10 1921.

BARING, MAURICE (1874–), English diplomat and man of letters, fourth son of the first Lord Revelstoke (*see* 3.401), was born in London April 27 1874. Educated at Eton and Trinity College, Cambridge, he entered the diplomatic service in 1898, but resigned in 1904. Taking to literature and journalism, he acted also at various times as a war correspondent for *The Times* and for the *Morning Post;* but he cultivated *belles lettres* for the most part, and his poems and essays soon gained high critical approval. During the World War he worked on the staff of the R.F.C. in France and also at home. In addition to various volumes of imaginative literature—poems, parodies and critical essays—he published several works on Russia, especially *The Russian People* (1911); *What I Saw in Russia* (1913); *The Mainsprings of Russia* (1914), etc. In 1920 he also published *R.F.C.H.Q. 1914–18*, an account of his experiences in France.

BARKER, SIR JOHN, 1st Bart. (1840–1914), British merchant, was born at Loose, near Maidstone April 5 1840. He was the son of Joseph Barker, a brewer, and founded the firm of John Barker & Co., Ltd., linen-drapers of Kensington, having previously been associated with the fortunes of Whiteley's, Westbourne Grove. He entered the House of Commons for Maidstone in 1900 but was unseated on petition. From 1906 10 he represented Penrhyn and Falmouth. In 1908 he was created a baronet. He took great interest in agriculture and did a good deal for horse-breeding. He died at Bishop's Stortford Dec. 16 1914.

BARNABY, SIR NATHANIEL (1829–1915), British naval architect, was born at Chatham in 1829, his father being a member of a family of shipwrights who for several generations had served in the royal dockyards. He was entered as an apprentice to his father's trade at the age of 14, and in 1848 won an Admiralty scholarship to the Portsmouth school of naval engineering, where he obtained distinction. He was appointed a draughtsman in the royal dockyard at Woolwich (1852), passing later to the constructive department at the Admiralty and becoming its head in 1870. Two years later he was appointed Chief Naval Architect, a title changed in 1875 to Director of Naval Construction. His work in that capacity is described in 24.894–5. On his retirement in 1885 he was created K.C.B. He died at Lewisham June 15 1915.

He wrote the articles Navy and Shipbuilding for the E.B., 9th ed., and published *Naval Development in the 19th Century* (1902) and other works on naval construction, as well as *Christmas 1892 in Connought: a Study of the Irish Question* (1893), and a collection of hymns, *Songs by the Way*.

BARNARD, GEORGE GREY (1863–), American sculptor (*see* 3.410), finished the Pennsylvania State Capitol group in 1911, and the pediments of the New York Public Library in 1914. His bronze statue of Lincoln, heroic in size, was unveiled in Cincinnati in 1917, and was highly praised by many admirers of Lincoln (*e.g.* by Miss Tarbell, his biographer, and by Theodore Roosevelt), but was called a caricature by many art critics. Mr. Robert Lincoln, the hero's son, objected to the proposed setting-up of replicas in London and Paris, and the council of the National Academy of Design issued a formal protest. A replica was unveiled at Manchester, England, in 1919.

BARNES, GEORGE NICOLL (1859–), British Labour politician, was born at Lochie, Scotland, Jan. 2 1859. For many years he worked as an engineer, and in 1892 was appointed assistant secretary of the Amalgamated Society of Engineers, becoming its general secretary in 1896. In 1903 he went with the Mosely educational commission to the United States. In 1895 he had unsuccessfully contested Rochdale, but in 1906 was elected as Labour member for the Blackfriars (now Gorbals) division of Glasgow, where he defeated Mr. Bonar Law. This seat he retained in the general elections of 1910 and 1918. On Mr. Lloyd George's accession to power in 1916, Mr. Barnes joined his ministry as Minister of Pensions, and the same year was sworn of the Privy Council, but in Aug. 1917 resigned his office in order to enter the War Cabinet as representative of Labour, succeeding Mr. Arthur Henderson. In 1918 when the Labour party left the Coalition Mr. Barnes continued in the Coalition Government as minister without portfolio. He attended the Peace Conference at Paris as a Labour representative, and afterwards attended the International Labour Conference at Washington. He resigned in Jan. 1920 from the Cabinet.

BARNETT, JOHN FRANCIS (1837–1916), English musical composer (*see* 3.414), died in London Nov. 24 1916.

BARNETT, SAMUEL AUGUSTUS (1844–1913), English divine and social reformer (*see* 3.414), died at Hove June 17 1913.

See *Life* by Mrs. Barnett (1919).

BARR, AMELIA EDITH (1831–1919), author, was born at Ulverston, Lancs., England, March 29 1831. She was educated at the Glasgow, Scotland, high school. She married Robert Barr in 1850 and four years later they emigrated to Texas. Here, in 1867, she lost her husband and three sons through yellow fever. In 1869 she removed with her three daughters to New York where she wrote for the *Christian Union* and other periodicals. She continued to write unceasingly until 86 years of age, publishing altogether some 75 novels. She died in New York City, March 10 1919.

Her works include the following: *Romance and Reality* (1872); *Jan Vedder's Wife* (1885); *A Bow of Orange Ribbon* (1886); *A Border Shepherdess* (1887); *Remember the Alamo* (1891); *Prisoners of Conscience* (1897); *Master of His Fate* (1901); *The Reconstructed Marriage* (1910); *Playing with Fire* (1914); *Measure of a Man* (1915); *The Winning of Lucia* (1915); *Profit and Loss* (1916); *Joan* (1916); and *An Orkney Maid* (1917).

BARR, ROBERT (1850–1912), British novelist, was born at Glasgow Sept. 16 1850 and taken to Canada when four years old. He was educated at the Normal school, Toronto, and became headmaster of the public school of Windsor, Ont., until 1876, when he joined the editorial staff of the *Detroit Free Press*. He had an adventurous career as a journalist for five years, and in 1881 came to England. In 1892 he started the *Idler* together with Mr. Jerome K. Jerome. He published a number of novels and short stories, the best known being *The Mutable Many* (1897); *Countess Tekla* (1899) and *The Sword Maker* (1910). He died at Woldingham, Surrey, Oct. 21 1912.

BARRACKS AND HUTMENTS, Great Britain (*see* 3.427). The earlier article brought the account of this branch of military administration up to about 1904. It showed the principles on which British barrack design was based (viz: on the "Barrack Synopsis" and Standard Plans) and the provision which had been authorized in such matters as the numbers in one room, provision of dining-rooms and baths and other sanitary services, in the British army at home and in India. It mentioned

that in 1904 an architectural branch had been formed at the War Office, under civil control, for new barracks and hospitals at home stations; while services of a minor nature at home, and all services abroad, were carried out as heretofore, under the Royal Engineers. It remains here to show, as a sequel, how the "steady and systematic progress" already indicated, prior to 1904, was continued in the following decade, until, in the period of the great World War, the civil branch ceased to exist. During that decade many new works were carried out, some of them by the new civilian architects, and others by military engineers. Broadly speaking, those carried out under the former administration were of a substantial and permanent type, while the latter constructed those of a less solid and less ornate character, applicable to the exigencies of locality.

It is necessary, however, first to mention one important development of administration which had reference to this among other subjects affecting the soldier's well-being. In 1906 a Medical Advisory Board was instituted, consisting not only of eminent military medical officers, but also of distinguished medical men in civil life, the very best expert opinion in England on sanitary questions of all sorts. With them was associated an engineer officer of high rank. To this Board was referred all designs for barracks and hospitals at home and in foreign stations other than India, and their authority on all questions affecting housing was necessary before schemes could be sanctioned. They selected or approved all sites for dwellings—whether for barracks, married men's quarters, or hospitals—and they were referred to in all alterations to the Synopsis or Standard Plans. During the war their functions were carried out by an Army Sanitary Committee, which, under the chairmanship of an officer of high rank, made frequent tours in the theatre of war and in all hutted camps, etc., in Great Britain.

Permanent Barracks.—The principal permanent British barracks (using their term to distinguish the type from those of "light construction") which were built during the decade 1904–14, were those for one battalion of infantry and one regiment of cavalry, near Edinburgh, at Redford.

The plan of the barrack building forms three sides of a quadrangle, and the buildings are three stories high. The ground floors are occupied with recreation and games' rooms on a generous scale, a sergeants' mess, regimental offices and shops, and other accessories, while the upper floors are used for the men's dormitories, and are divided up so that each man has a cubicle to himself. The dining-rooms and cook-houses, etc., occupy the space in the interior of the quadrangle. The whole scheme was on a scale of generosity far beyond anything hitherto constructed. The fact that it was designed with freedom from the restrictions hitherto imposed by standardization was a potential advantage, for it is only by independent thought that progress can be attained in any appreciable degree in this or any other branch of scientific experiment. But the advantages gained by such treatment of design have to be weighed against the disadvantages, viz:—the extra expense for housing even one unit, amounting to about 80% over the last approved type, and the time taken to build, which was also proportionally greater. It is also doubtful whether the arrangement of having the dormitories available for night use only—as was the intention—is as satisfactory from the point of view of military administration as the system, which it had superseded, of having men living together in groups of 10 or 12 with the intimacies and comradeship thus entailed.

At the Redford barracks the officers' quarters are in a separate block, together with the men's the whole forming a handsome building, and the married men's quarters are also separate.

Light-Construction Barracks.—About 1906–7 proposals were made to the Army Council of a somewhat novel principle in constructional work. Hitherto it had been always accepted as an axiom in military buildings that the more substantial and permanent the construction, the better, on the ground that although the first cost might be greater than that of a temporary building, such as a wooden hut, the cost of repairs for the latter worked out at so much higher a figure and the life of the building was so much shorter, that it was true economy in the end to build as solidly as possible. The cost of repairs in a solid well-built barrack might be between 0·75 and 1·25% of the capital value, but that of huts might run to 3 or 4%. It was pointed out in 1907, however, that this was a fallacious argument to apply to buildings which were required for a service subject both to frequent changes of policy and to changes of standard imposed by progress in science. Thus the Royal barracks in Dublin, which in the reign of Queen Anne were considered the finest in Europe, were in the reign of Queen Victoria still standing, solid and substantial, but the despair of every sanitary expert. The same applies to many barracks (and, it may be added, to many civil hospitals) in many parts of the British Empire. It was argued, therefore, that constructional science had now reached a point where it was possible to build in a manner much less expensive, much more rapidly erected, and much more easily altered than the solid walls and heavy roofs of our fathers, and that such buildings, not much more expensive than temporary huts, could be made to suit military needs; and that the cost of maintenance would be no greater than that entailed in the case of more substantial works. Any one acquainted with the routine of military administration is familiar with the constant "reappropriations" that have to be made to suit some change in the requirements of accommodation. A row of married men's quarters has to be turned into a temporary, or even permanent, hospital, or a forage barn has to be made into a school, a gun-shed into a recreation room. With solid old masonry this became a serious and expensive matter. The whole subject required reconsideration.

Just then an opportunity occurred of making the experiment on a fairly wide scale. In the earthquake at Kingston, Jamaica, civil and military houses alike were shattered in a few seconds. The barracks, for about 800 men, with church, hospital and all administrative offices and staff quarters, had been of the old solid type. They were gone, and had to be replaced at once. Urgent representations to England pointed out that remedial measures must be instant, that there was neither material nor labour available locally, and that new plans should be proof against earthquakes and hurricanes.

It was decided at once to build the new barracks with a skeleton steel framework, vertical steel stanchions, braced below by steel horizontal joists, and above by a composite steel and wooden truss. The stanchions were rooted, as it were, by a broad flat plate, in a concrete block in the ground, and they were calculated to carry the whole weight of floors, walls, roof and any other contingent matters such as windows, doors, shelves, etc. The walls, which carried no weight, but were merely screens from weather, were composed of a double panelling of metal lathing plastered over and fastened to the steel stanchions. Being double, the space between the two sets of panels acted as a non-conductor of temperature. The whole of the work was quickly designed and the material quickly prepared. A firm of English contractors erected the skeleton of each building on their own premises, marked every part on a key plan, and the whole was dispatched from Bristol under charge of an experienced foreman of works, while a company of R. E. under a selected officer had meantime been dispatched, soon after the disaster, to erect the first building and arrange preliminaries for the others.

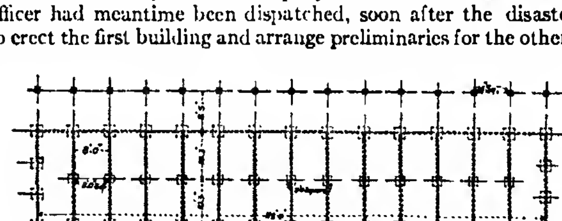

FIG. 1.

Figs. 1, 2, 3 and 4 show the plans and section of the main barracks buildings. The roof has a steep slope, partly to throw off tropical rain quickly, partly to allow locally obtained wooden shingles to be used as a fairly cool covering. The floor is raised 4 ft. above the ground, with a clear space beneath, the whole area below being covered with a seal of concrete to prevent exhalations from the soil. In this design the saving in walls and foundations is obvious, while the advantage in respect of stability, arising from the strength and continuity of the steel and its attachment to the foundation blocks, is also evident. As a matter of fact, there was another earthquake

Fair (1912); and the fine Hebridean Symphony (1916) for the publication of which the Carnegie Trust made themselves responsible. His great choral symphonies, for instance, *Atalanta*, a colossal work for unaccompanied choirs, occupying about 45 minutes in performance, and its companion, *Vanity of Vanities* (1914), are remarkable examples of his work. Bantock was largely instrumental in establishing the Birmingham competition festivals in 1912 and in increasing their efficiency.

BARCLAY, FLORENCE LOUISA (1862–1921), English novelist, was born at Limpsfield, Surrey, Dec. 2 1862, the daughter of the Rev. S. Charlesworth, rector of the parish, and niece of Maria Louisa Charlesworth, author of *Ministering Children.* On March 10 1881 she married the Rev. Charles Barclay, vicar of Little Amwell, Herts. Her first novel, *The Wheels of Time*, appeared in 1908, but she is best known by its successor, *The Rosary* (1909), which reached a circulation of close on a million copies and was translated into many languages. The combination of religious feeling and strong love interest which characterized most of her novels appealed to a very wide public, and she enjoyed for some years an immense popularity, the total circulation of her books exceeding 2,500,000. Later novels included *The Mistress of Shenstone* (1910), specially filmed in America; *The Following of the Star* (1911); *The Broken Halo* (1913); *In Hoc Vince* (1915); *Returned Empty* (1920). She died at Limpsfield March 10 1921.

BARING, MAURICE (1874–), English diplomat and man of letters, fourth son of the first Lord Revelstoke (*see* 3.401), was born in London April 27 1874. Educated at Eton and Trinity College, Cambridge, he entered the diplomatic service in 1898, but resigned in 1904. Taking to literature and journalism, he acted also at various times as a war correspondent for *The Times* and for the *Morning Post;* but he cultivated *belles lettres* for the most part, and his poems and essays soon gained high critical approval. During the World War he worked on the staff of the R.F.C. in France and also at home. In addition to various volumes of imaginative literature—poems, parodies and critical essays—he published several works on Russia, especially *The Russian People* (1911); *What I Saw in Russia* (1913); *The Mainsprings of Russia* (1914), etc. In 1920 he also published *R.F.C.H.Q. 1914–18*, an account of his experiences in France.

BARKER, SIR JOHN, 1st Bart. (1840–1914), British merchant, was born at Loose, near Maidstone April 5 1840. He was the son of Joseph Barker, a brewer, and founded the firm of John Barker & Co., Ltd., linen-drapers of Kensington, having previously been associated with the fortunes of Whiteley's, Westbourne Grove. He entered the House of Commons for Maidstone in 1900 but was unseated on petition. From 1906 to he represented Penrhyn and Falmouth. In 1908 he was created a baronet. He took great interest in agriculture and did a good deal for horse-breeding. He died at Bishop's Stortford Dec. 16 1914.

BARNABY, SIR NATHANIEL (1829–1915), British naval architect, was born at Chatham in 1829, his father being a member of a family of shipwrights who for several generations had served in the royal dockyards. He was entered as an apprentice to his father's trade at the age of 14, and in 1848 won an Admiralty scholarship to the Portsmouth school of naval engineering, where he obtained distinction. He was appointed a draughtsman in the royal dockyard at Woolwich (1852), passing later to the constructive department at the Admiralty and becoming its head in 1870. Two years later he was appointed Chief Naval Architect, a title changed in 1875 to Director of Naval Construction. His work in that capacity is described in 24.894–5. On his retirement in 1885 he was created K.C.B. He died at Lewisham June 15 1915.

He wrote the articles Navy and Shipbuilding for the E.B., 9th ed., and published *Naval Development in the 19th Century* (1902) and other works on naval construction, as well as *Christmas 1892 in Connought: a Study of the Irish Question* (1893), and a collection of hymns, *Songs by the Way.*

BARNARD, GEORGE GREY (1863–), American sculptor (*see* 3.410), finished the Pennsylvania State Capitol group in 1911, and the pediments of the New York Public Library in 1914. His bronze statue of Lincoln, heroic in size, was unveiled in Cincinnati in 1917, and was highly praised by many admirers of Lincoln (*e.g.* by Miss Tarbell, his biographer, and by Theodore Roosevelt), but was called a caricature by many art critics. Mr. Robert Lincoln, the hero's son, objected to the proposed setting-up of replicas in London and Paris, and the council of the National Academy of Design issued a formal protest. A replica was unveiled at Manchester, England, in 1919.

BARNES, GEORGE NICOLL (1859–), British Labour politician, was born at Lochie, Scotland, Jan. 2 1859. For many years he worked as an engineer, and in 1892 was appointed assistant secretary of the Amalgamated Society of Engineers, becoming its general secretary in 1896. In 1903 he went with the Mosely educational commission to the United States. In 1895 he had unsuccessfully contested Rochdale, but in 1906 was elected as Labour member for the Blackfriars (now Gorbals) division of Glasgow, where he defeated Mr. Bonar Law. This seat he retained in the general elections of 1910 and 1918. On Mr. Lloyd George's accession to power in 1916, Mr. Barnes joined his ministry as Minister of Pensions, and the same year was sworn of the Privy Council, but in Aug. 1917 resigned his office in order to enter the War Cabinet as representative of Labour, succeeding Mr. Arthur Henderson. In 1918 when the Labour party left the Coalition Mr. Barnes continued in the Coalition Government as minister without portfolio. He attended the Peace Conference at Paris as a Labour representative, and afterwards attended the International Labour Conference at Washington. He resigned in Jan. 1920 from the Cabinet.

BARNETT, JOHN FRANCIS (1837–1916), English musical composer (*see* 3.414), died in London Nov. 24 1916.

BARNETT, SAMUEL AUGUSTUS (1844–1913), English divine and social reformer (*see* 3.414), died at Hove June 17 1913.

See *Life* by Mrs. Barnett (1919).

BARR, AMELIA EDITH (1831–1919), author, was born at Ulverston, Lancs., England, March 29 1831. She was educated at the Glasgow, Scotland, high school. She married Robert Barr in 1850 and four years later they emigrated to Texas. Here, in 1867, she lost her husband and three sons through yellow fever. In 1869 she removed with her three daughters to New York where she wrote for the *Christian Union* and other periodicals. She continued to write unceasingly until 86 years of age, publishing altogether some 75 novels. She died in New York City, March 10 1919.

Her works include the following: *Romance and Reality* (1872); *Jan Vedder's Wife* (1885); *A Bow of Orange Ribbon* (1886); *A Border Shepherdess* (1887); *Remember the Alamo* (1891); *Prisoners of Conscience* (1897); *Master of His Fate* (1901); *The Reconstructed Marriage* (1910); *Playing with Fire* (1914); *Measure of a Man* (1915); *The Winning of Lucia* (1915); *Profit and Loss* (1916); *Joan* (1916); and *An Orkney Maid* (1917).

BARR, ROBERT (1850–1912), British novelist, was born at Glasgow Sept. 16 1850 and taken to Canada when four years old. He was educated at the Normal school, Toronto, and became headmaster of the public school of Windsor, Ont., until 1876, when he joined the editorial staff of the *Detroit Free Press.* He had an adventurous career as a journalist for five years, and in 1881 came to England. In 1892 he started the *Idler* together with Mr. Jerome K. Jerome. He published a number of novels and short stories, the best known being *The Mutable Many* (1897); *Countess Tekla* (1899) and *The Sword Maker* (1910). He died at Woldingham, Surrey, Oct. 21 1912.

BARRACKS AND HUTMENTS, Great Britain (*see* 3.427). The earlier article brought the account of this branch of military administration up to about 1904. It showed the principles on which British barrack design was based (viz: on the "Barrack Synopsis" and Standard Plans) and the provision which had been authorized in such matters as the numbers in one room, provision of dining-rooms and baths and other sanitary services, in the British army at home and in India. It mentioned

cost, more especially as there was substantial saving in having the three buildings, canteen, institute and dining-rooms, combined in one.

As the light-construction principle became more established in favour for buildings, including hospitals, in country districts especially, designs were contemplated for larger schemes (*e.g.* for the cavalry brigade barracks at Chiseldon, Wilts., and for an artillery brigade barracks near Fermoy), at the time of the outbreak of the war in 1914, and were in part carried out. In 1912–4 this principle of design was mainly adopted in connexion with aviation buildings, required by the new R.F.C. The variety of new buildings, aeroplane sheds, workshops, instructional buildings, etc., that were involved was great, and the urgency for their provision very pressing. A system of construction, therefore, which would lend itself to quick completion, not involve heavy expenditure, and be capable of expansion, was obviously suited to a service of which the full requirements were still conjectural.

Allusion may be made to one particular development, for it applied to other branches of the service as well as to aviation. This was the construction of officers' messes and quarters. Hitherto, in permanent barracks everywhere, these had been combined in one continuous building, and, when enlargement or alteration of the mess became necessary, the problem was difficult. With the new arrangement for the R.F.C., the mess-house was designed separately, generally built on a site fairly central for groups of officers' cottages erected near it. Each cottage contained rooms for four single officers or two field officers, with an annex behind, containing servants' rooms, store-rooms, bath-room, etc. If the establishment of officers increased, more cottages could be built; if the numbers were reduced, one or more buildings could be shut up or reappropriated. This form of accommodation was very popular.

Married Soldiers' Quarters.—Accommodation for the married soldier had in earlier years been brought up to a reasonable standard of comfort and decency. The standard plans of married quarters, however, were neither economical in first cost nor pleasant in appearance. Frequently built in long and monotonous rows, they resembled the mean streets of an industrial town, and occupying, as they often did, some lovely spot in rural England, they were an eyesore and reproach. Hence, during the decade 1904–14, much attention was paid to (*a*) reduction in cost, and (*b*) improvement in external treatment. As regards (*a*) the average cost of the standard design was £400 per quarter of four rooms, and it was found that by rearrangement in constructive details, reducing height of rooms, rearrangement of chimneys, etc., the price could be reduced to about £220–£250 without sacrifice of comfort or authorized accommodation. Greater attention to (*b*) was possible also, in combination with economy; and the grouping of rows of quarters round gardens, playgrounds, etc., gave an impression of home life in country districts. Some groups of such cottages at Farnborough, Hants., were visited in 1917 by the Local Government Board Committee on the National Housing Problem, and elicited their full approbation.

Hutting during the War.—When accommodation for the new armies first came to be considered by the British War Office in the first 10 days of the World War, it was definitely decided to adopt some cheap design of hut which could be readily erected, and also easily adapted to any form of temporary material and to any reasonably level site. But there were many other considerations, *e.g.* what nature of accessory accommodation should be given, in view especially of recent rules regarding dining and recreation rooms, what sort of sanitary provision should be made, what method of lighting should be adopted, etc. As a result of consultation between the various War Office departments concerned the following points were settled: (*a*) That huts to hold 25 men (including one sergeant) should be constructed, giving 48 sq. ft. floor area per man (about 400 cub. ft. of interior space); (*b*) that there should be two principal spans of huts, viz. 20 ft. and 28 ft., and that as far as possible all the various buildings should be planned to fit one or other of these, so as to simplify the construction; thus, men's barracks, officers' quarters, regimental offices, quartermaster's stores, officers' mess and ante-room and kitchen, sergeants' mess and kitchen, were all planned to fit into the 20-ft. span, while men's dining-rooms, cook-house and regimental institute were on the 28-ft. span; (*c*) that there should be a battalion cook-house, fitted with the best known pattern of cooking-range and boilers for 1,000 men, and that there should be on either side of it dining-rooms for 500 men each, allowing 5 to 6 sq. ft. for each man on a total floor space of 2,800 sq. ft. Between the cook-house and the dining-rooms there should be sculleries; (*d*) that there should be in each battalion a bath-house with a central heating boiler and hot and cold water laid on to the showers, which should be in the proportion of 5 to every 100 men; (*e*) that there should be a regimental institute of three rooms, viz. supper room, games room, and corporals' room; the bar and beer cellar to be between the supper room and corporals' room so that central serving could be arranged. There was also provided a kitchen and scullery in an annex. There was to be no "wet" canteen (though as a matter of fact some commanding officers made a canteen out of the corporals' room—an arrangement which was

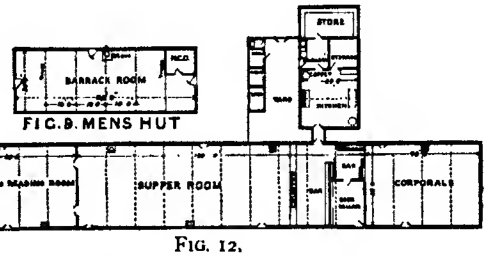

FIG. 12.

not in accordance with the original intention); (*f*) that there should be officers' and sergeants' messes planned to accommodate 30 officers and 50 sergeants respectively, and consisting of one block with mess-room and ante-room joined by a short passage with a kitchen block; (*g*) that four drying-rooms should be provided in which wet clothing could be hung, fitted with stoves and bars; (*h*) that the latrines should be on the dry-earth system, and that the ablution rooms and urinals should either lead into soak pits (in the chalk country in France this was invariably done) or into sewage filters; (*i*) that the lighting should be done by electric lamps and the wires carried on poles, not buried.

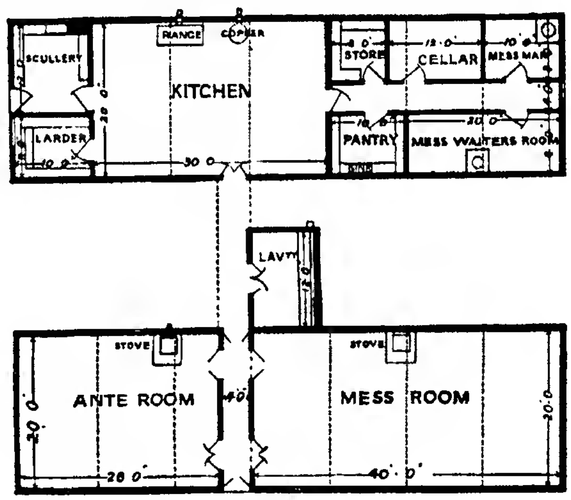

FIG. 10.

Plans of the principal huts designed on the above decisions are shown in figs. 9 to 12.

That these points were speedily settled is proved by the fact that all the type plans in detail for a complete battalion camp were approved 10 days after war was declared, and three days after it was decided to raise 100,000 men for the new army.

Considering the urgency of the matter, it would not have been a matter for surprise if extensive changes had to be made after the camps, so built, came into use. There were not, however, many changes, though several details were amended. Thus, it was decided to omit some of the accessories, such as the dining-rooms, on the ground that the men could dine in their sleeping-huts if necessary, and dining-rooms were only a recently authorized provision. The drying-rooms were frequently used for purposes other than that for which they were built, and in many camps they were not used at all, as the men found they lost their clothing when mixed up with others. In matters of detail, it was found better to have the huts made up in sections, bolted together *in situ*, rather than to build up with gangs of carpenters on the spot. This building by sections enabled the work to be done chiefly in central workshops and very rapidly put together on the site. Incidentally, sectional huts fetched a better price after the war than others, for obvious reasons.

As regards materials, the huts were at first founded on brick piers. This was a mistake, and it would have been better from the outset to

have had a short stout pile of creosoted wood. The brick piers involved bricklayers and bricks and mortar, and the provision of these meant delay in some cases. The framework of walls, roofs and floors was mainly red fir of market scantlings, but the multiplication of these scantlings caused a famine in the market and much complaint. Yet it is hard to see how this could have been avoided, except by using a material more costly, or else by taking more time in construction. A light steel framework was used in some cases, with expanded metal plastered on one side, and sheet iron painted in the interior of the room, but this was costly compared to timber. For lining match-boarding and 3-ply timber were used. Asbestos sheets

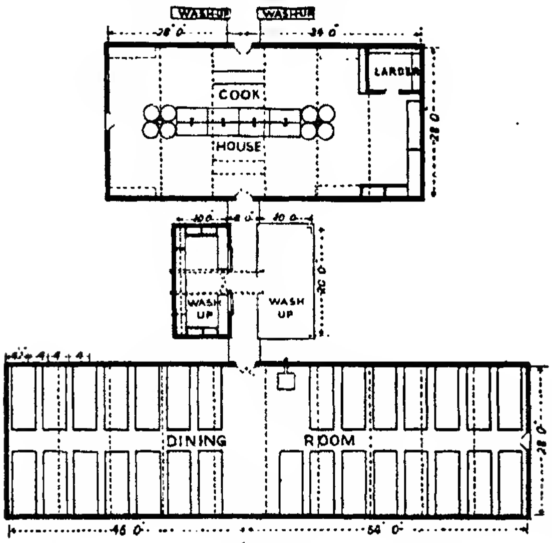

FIG. 11.

were used at first but were found very brittle unless the backing of timbers was fairly (say 18 in.) close, and "S X boarding" and similar fibrous matter was also employed, but not found suitable.

The floors were in most cases of planking, grooved and tongued.

In France excellent sectional huts were made up by French workmen, and the carpentry was somewhat on different lines to that employed in England, lighter scantlings in roofs and subsidiary ties and struts being used. Many of the sectional huts there had the sides at a slight angle to the vertical, the sloping side forming like a "mansard" roof, part of the truss supporting the roof-covering.

Hospitals.—It was pointed out in the earlier article that military hospitals, where built permanently, are designed on much the same lines as those in civil life.

During the decade before the World War there were two large permanent hospitals built for military needs, at Portsmouth and Dublin, but there were many small "reception stations" for examination, observation, accidents, etc., and one fairly big hospital for women, built of light construction, and found to be most satisfactory in every way.

When the war broke out in 1914 the whole question of suitable hospital design came necessarily into great prominence, and the following were the main points which were then settled:—(*a*) The wards should contain 25 beds, *i.e.* 24 ordinary cases and one special case in a separate small room; (*b*) the nurse's duty room should be adjacent to the entrance to the main ward, divided by the central passage from the special-case ward; (*c*) beyond the nurse's duty room should be the ward scullery and on the opposite side of the central passage the linen cupboard; (*d*) beyond this a transverse passage so as to give clear ventilation between the foregoing parts of the ward and the ablution and bath-rooms, which come then at the end of the hut nearest to the main entrance.

This gives a hut 140 ft. long by 20 ft. 8 in. wide (see fig. 13). Of the total area a little more than one-fourth is taken up by accessory accommodation, and it is doubtful whether as much as one case out of 24 requires to be specially treated. However, the above represented what may be called the nucleus typical ward, and hundreds were erected either exactly the same as this or with minor modifications, both in England at the large training-centres, and in France in the area occupied by British troops.

The administrative offices, which are always an important adjunct in a hospital, were combined in a hut 160 ft. by 28 ft., shown in fig. 14. At one end is the out-patient department with consulting-room, waiting-room and dispensary, divided by a corridor from the offices of the principal medical officer, his clerks and registrars, beyond which are the offices of the matron, nursing sisters' duty room, and clinical laboratory. At the rear of these are the orderly medical officers' room and the medical board room.

In the field there was in some cases a reception block where all wounded cases were brought, given temporary treatment, food, etc., and examined by the medical officers prior to being sent to one or other of the special wards for surgical attention, etc.

In a typical operation hut, 51 ft. by 36 ft., a wide double door, to admit a stretcher, leads into a hall, from which open on one side a Röntgen-ray room, an anaesthetic room, and the operation room, while on the other side are the sterilizing-rooms, preparation room, store and photographic rooms. The patient, after X-ray examination, is taken into the anaesthetic room and thence, when unconscious, into the operation room, about 20 ft. square, with windows opening to the north.

The hospital arrangements in the field varied in some nature of detail, but the same general principles were followed.

Hospital kitchens were based on the knowledge that, while some patients could come to a dining-room, there were many who would

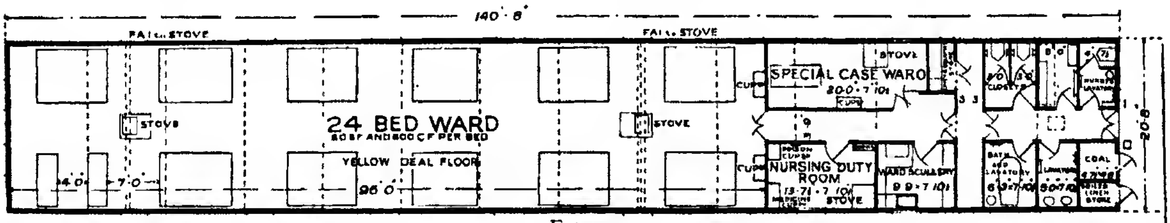

FIG. 13.

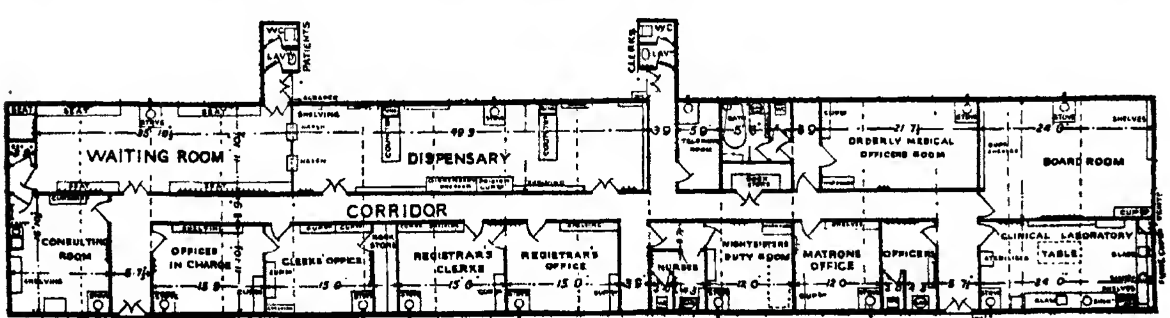

FIG. 14.

have to be fed in their beds, and that the diets would have to be varied to suit individuals. The cooking and distribution arrangements had therefore to be on a more elaborate plan than is provided for in ordinary barracks.

Other hospital buildings, such as dining-room, supply stores (for bedding and utensils), pack store, officers' quarters, nursing sisters' accommodation, and barrack huts for orderlies, followed the usual lines for ordinary barrack huts and quarters with certain modifications. There were, however, two other adjuncts of importance in field hospitals, viz. mortuary block, and disinfecting block, which deserve a brief description.

The former is a hut 30 ft. by 14 ft. 8 in., with a post-mortem chamber 14 ft. by 11 ft. 9 in. at one end, fitted with table, stove, cupboard, sink and shelves, and with wide double doors. Next to it is the body chamber, about 8 ft. square, and beyond that a "viewing chamber," entered by a separate lobby where friends of the deceased can enter and see the corpse prior to burial.

The disinfecting-hut has a receiving-room 11 ft. 9 in. by 14 ft., into which the foul clothing, bedding, etc., is brought, and placed in an air-tight disinfector, one end of which opens into the receiving-room, and the other into an adjacent chamber, the issuing-room, whence, after treatment in the disinfector, the material is removed. There is a small incinerator in another chamber and, for those materials which require liquid disinfectants, there are other rooms provided.

Portable Huts of Special Design.—There were many types of portable light huts made of wooden framework and canvas. They were not found satisfactory for prolonged use, although many were found very useful for rapid work and in emergencies. The principles were the same in most cases, viz. framing of wooden scantlings about 2 in. by 1¾ in., covered with canvas prepared with some sort of waterproof solution, and, when unfolded, fixed in position by light bolts or by hooks. The disadvantages were that they did not afford better protection against cold and heat than tents, and that the edges of the framing caused the parts of the canvas in contact with them to wear rapidly.

Portable huts of corrugated steel bent to a circular form were, however, most useful. The model invented by Lt.-Col. Nissen, R.E., was largely used in the field. These huts were in two patterns, differing from one another only in the fact that in the larger one there was a central ridge opening admitting air and light along the summit above the normal roof level. The huts were formed of light steel ribs of H-section bent in a semi-circular form, and resting on plates for foundations. Over these, corrugated steel in three parts, clipped together at the edges, and fastened to the ribs, is laid. Under the corrugated steel, and fitting into the flanges of the ribs, are light boards to form a lining. The floors, of wood, are made in sections and fit in between the parts of the steel framing that reach the ground. At the ends of the huts are doors and windows, with match-boarding to fill the unoccupied spaces. Thus the corrugated steel covering forms roof and walls, while light and ventilation, etc., is obtained from each end. The great advantage of these huts was that the materials could be packed up together so as to take up little space; and the one disadvantage was that, at a time when steel was much required for other services, it was difficult to get supplies of these huts in large numbers.

It is probable that sectional huts, either of the pattern alluded to above, or of some modification of the Nissen patent, will be considered as articles of recognized equipment in future and kept in store. (G. K. S. M.)

UNITED STATES

In times of peace the provision and upkeep of quarters for U.S. troops had been the function of the Construction and Repair Division of the quartermaster-general's office. The permanent military posts were small and in the aggregate provided housing for only about 107,340 officers and men. Upon America's entrance into the World War the subsequent drafting of large numbers of men demanded an unprecedented rapidity of construction. Existing facilities were wholly inadequate. As authorized by a letter of the adjutant-general, May 19 1917, a separate Cantonment Division was created in the office of the quartermaster-general, reporting directly to the Secretary of War, and charged with the formidable task of housing the new army. On Oct. 10 1917, the old Construction and Repair Division was abolished and its duties given to the new organization, which in Feb. 1918 was placed under the Operations Division of the office of the chief-of-staff. It was thus detached from the office of the quartermaster-general as an independent service. On March 13 1918 its name was changed to the Construction Division.

On May 17 1917, one month after the declaration of war, the commanding generals of the different military departments were ordered to select 16 sites for the erection of cantonments (National Army Cantonments) to receive the troops to be chosen by the selective draft and also 16 sites for camps of the mobilized National Guard (National Guard Camps). Already in April tentative plans had been drawn for barracks and mess-halls, these to be wooden structures one storey in height, 20 ft. wide and of varying length, and this type was used for certain buildings in the National Guard Camps, in which, however, the troops were housed under canvas. These camps were all situated in the southern states, and required less protection against cold. Actual construction of cantonments began late in June and of camps about a month later. The last cantonment site was chosen July 6. It was necessary that the 32 mobilization centres be ready for the reception of the first contingents within 90 days. The cantonments naturally presented the most difficult construction problem, but by Sept. 4 they were prepared to house 430,000 men and their capacity was increased to 655,000 by the close of 1917 and subsequently expanded to 770,000. The National Guard camps provided quarters for 450,000 officers and men. At the regular army posts provision was made for accommodating 140,000 additional men. The programme of construction included also 4 centres of embarkation, 22 special camps, 30 supply depôts and numerous other establishments. At the Armistice, Nov. 11 1918, the total capacity of all the military establishments in the United States was more than 1,700,000 troops.

In laying out the cantonments on the chosen sites experts in town-planning gave advice. In general a U-shaped plan was adopted in which the wings could be extended indefinitely. In practice this general plan had to be adapted in each case to the local terrain. Standardized basic units of construction were devised, but these of necessity depended upon the size of the infantry companies to be accommodated. It was known that the original company of 150 men would be enlarged, but it was not known to what extent. For the 16 cantonments plans were issued calling for 2-storey wooden buildings, 43 ft. wide, of varying length, to house a company of 200 men or less, each building to have mess-halls and barracks. In the case of sites in the northern part of the United States, the barracks were lined with wall-board, with interior air space as a protection against the cold; in the South, barracks were merely double-boarded on the outside. Enclosed stables were built in the North; open sheds for animals in the South. As originally designed these barracks provided less than 400 cub. ft. of air space per man, following the regulations then in force for tent quarters. In Sept. 1917, after construction was almost finished, orders were issued calling for at least 500 cub. ft. of air space per man both in wooden barracks and in tents. At the same time it was announced that infantry companies were to be increased to 250 men. It was further ordered that not more than 35 men should be housed in one room and that each room should have four outside walls with windows and should have an independent entrance. This required a complete rearrangement of barrack interiors and much additional construction so that one company could be quartered in two adjacent buildings. For subsequent construction of barracks new plans were drawn, calling for buildings of a maximum size of 30 by 60 ft., 2-storeys high, with accommodations for 66 men. For a single company four such barracks were required, besides separate buildings for mess-halls and lavatories. In the beginning one-storey quarters for officers had been designed and these were retained throughout the period of mobilization. As to the grouping of buildings, a standard block about 450 by 800 ft. was chosen. Each block contained barracks for eight companies of 250 men. Beyond one end of the block were the officers' quarters; at the opposite end were placed the stables. In constructing rows of buildings the general plan was to leave at least 500 ft. between the rows as protection against the spread of fire. In each row not more than two blocks were grouped; further groups were separated by at least 300 ft. Strict regulations were observed in the setting of stoves and heaters, and all electrical work conformed to the National Electric Code. Water connexions were so placed that 16 streams could be thrown upon a large building. At each mobilization centre there was a trained military fire company and full equipment. In addition to quarters for troops a cantonment had a remount station for 10,000 animals, railway sidings, clothing repair shops, steam laundries, bakeries, refrigerating plants, electric power plants, storehouses, halls for instruction, and a base hospital. Camp welfare buildings were also maintained by such organizations as the Y.M.C.A., Knights of Columbus and Red Cross.

A special Hospital Division was organized under the office of the surgeon-general to provide adequate military hospitals at camps and cantonments. In the autumn of 1917 these 32 centres each had fully equipped hospital facilities with a combined capacity of 44,000 beds. The larger base hospitals had a capacity of 1,000 beds, and comprised 60 buildings built at least 60 ft. apart, all connected by enclosed corridors. They had separate steam-heating plants and laundries, and were equipped with modern plumbing. Each ward had a capacity of from 60 to 80 beds and provided usually 1,000 (never less than 800) cub. ft. of air per patient. The buildings were of the 2-storey type. In addition each regiment possessed a medical dispensary and a small hospital containing 20 beds.

To provide water, connexion was made, when practicable, with the mains of existing systems. In other cases it was derived from wells or streams and, if advisable, thoroughly purified. In the cantonments the generous quantity of about 40 gal. a day per man was provided, and in addition about 15 gal. each for animals. In the camps the quantity made accessible was smaller as there was less danger of disastrous fires in quarters under canvas. For each company there was a lavatory with 12 vitreous bowls with wooden seats and a urinal trough 18 ft. long, besides 10 shower-baths and a wash

trough 22 ft. long; a storage tank of 560 gal. capacity attached to a heater supplied abundant hot water. Where possible the sewage was discharged directly into running streams; where desirable, septic tanks were installed for its treatment. Steam-heating was provided for all hospitals, and in four instances for the whole cantonment because of rigorous climatic conditions. In 12 cantonments and in the 16 camps stoves for heating were placed in the various apartments. Central power plants furnished electric lighting in all cases. No special type of road was required, but specifications were prepared for brick, cement concrete, bituminous macadam, and water-bound macadam. The width was usually 18 ft., but in some cases 24. Such walks as were built were usually of wood.

Tables I. and II., from official reports of the War Department, give the name and location of each cantonment and camp, the number of buildings erected and the amounts allotted for construction (from July 1 1917 to June 30 1918 inclusive):—

BARRÈS, MAURICE (1862–), French novelist and politician (*see* 3.434), published *La Colline inspirée* (1913); but after 1914 was occupied almost exclusively with subjects arising out of the World War. *La grande Pitié des Églises Françaises* (1914); *L'Âme française et la Guerre* (1915); *La Lorraine dévastée* (1919); *Le Roman de l'Énergie nationale* (1919) were amongst his later works. He also published literary addresses and lectures.

BARRIE, SIR JAMES MATTHEW, Bart. (1860–), British novelist and dramatist (*see* 3.435), devoted himself after 1910 almost exclusively to drama. He produced, amongst other plays, *Rosalind* (1912); *The Will* and *The Adored One* (1913); *Der Tag* (1914); *Rosy Rapture* (1915); *A Kiss for Cinderella* (1916); *Dear Brutus* (1917); and *Mary Rose* (1920). He was created a baronet in 1913.

BARRILI, ANTONIO GIULIO (1836–1908), Italian novelist (*see* 3.436), died Aug. 13 1908. His last work, a volume of poems, *Canzoni al vento*, was published posthumously in 1911.

BARRINGTON, RUTLAND [George Rutland Fleet] (1853–), English actor, was born at Penge, Kent, Jan. 15 1853, and was educated at Merchant Taylors' school. He appeared

first at the Olympic theatre, London, in 1874. Three years later he joined D'Oyley Carte's company at the Opera Comique and appeared in Gilbert and Sullivan's opera *The Sorcerer*. From that time onwards he was identified with the fortunes of the long series of these operas, which ran continuously from 1877 to 1889 and were revived at frequent intervals. In 1908 and 1911 he published two volumes of *Recollections*.

BARROW-IN-FURNESS, England (*see* 3.443).—The pop. (63,770 in 1911), which more than doubled during the World War, was estimated at 78,000 in 1920. The shipbuilding yards developed greatly and war vessels of all types, including dreadnoughts and submarines, were constructed during the war. The Cavendish dock adjoining the Ramsden dock on the E., 146 ac. in extent, has been leased by the Furness Railway Co. to the firm of Vickers Ltd. for the construction of airship sheds and for the manœuvring of airships and dirigibles. The airship factory is situated on Walney I., which is connected with the mainland by a bridge with an opening span of 120 ft. for the passage of vessels. Among the public buildings constructed since 1911 are the town hall with a clock tower 170 ft. high, built at a cost of £70,000, and a working-men's club and institute, the gift of a former mayor; a new Carnegie library was in course of erection in 1921.

Vickerstown on Walney I. is a rapidly growing township of model workmen's houses and is becoming more and more a residential suburb of Barrow. It has the James Dunn park on the E. and the Biggar Bank, a public recreation ground facing the Irish Sea, on the W. side of the island.

BARRY, ALFRED (1826–1910), English bishop (*see* 3.444), died at Windsor April 1 1910.

BARRYMORE, ETHEL (1879–), American actress, was born Aug. 15 1879 in Philadelphia, and was educated at the Convent of Notre Dame in that city. She made her début in 1896 in the company of her uncle, John Drew. In 1897 she first appeared in England in *Secret Service*, and with Sir Henry Irving's company in *The Bells* and *Peter the Great* (1898). She was first starred by Charles Frohman in *Captain Jinks* in 1900, and subsequently became one of the leading actresses in the United States.

Her brother, John Barrymore (1882–), who first appeared on the stage in *Magda* in 1903, had also, by 1921, established his position as one of the foremost American actors as had also another brother, Lionel, whose first appearance was in 1893.

BARTELS, HANS VON (1856–1913), German painter (*see* 3.447), died at Munich Oct. 5 1913.

BARTHOLOMEW, JOHN GEORGE (1860–1920), Scottish cartographer, was born in Edinburgh March 22 1860, the elder son of John Bartholomew, also a cartographer (*see* 3.450). J. G. Bartholomew was educated at the Edinburgh high school and university, and succeeded his father as head of the business of the Edinburgh Geographical Institute. In this capacity he maintained and improved the unsurpassed reputation for scientific cartography and exquisite reproduction which the firm had already acquired; in particular, he extended and popularized the use of "layer" colours exhibiting relief of the land, applying this method not only in the reduction of ordnance survey maps but in many other instances, including general atlases, of which the finest example is that published by *The Times* since the close of the World War. Bartholomew was associated with Sir John Murray and others in connexion with the mapping of results of the "Challenger" expedition, the bathymetrical survey of the Scottish lochs, and other scientific studies. He planned a physical atlas on a large scale and with the coöperation of Dr. A. J. Herbertson published the *Atlas of Meteorology* in 1899, which at once became a standard work. The volume on zoögeography, in collaboration with W. Eagle Clarke and P. H. Grimshaw, followed in 1911. His written works include a bibliography of authoritative maps of all countries (1891) and a gazetteer of the British Isles; and he interested himself greatly in geographical education, helping to found the lectureship in geography in the university of

Edinburgh, as well as the Royal Scottish Geographical Society. He was one of the founders and for many years hon. sec. of the Royal Scottish Geographical Society. He died at Cintra April 13 1920, but the management of the Edinburgh Geographical Institute remained in his family.

BARTHOU, LOUIS (1862–), French statesman, advocate, author, journalist, and lecturer, was born at Oleron Aug. 25 1862. He was elected to Parliament in 1889, and five years later he became Minister of Public Works. He was successively Minister of the Interior (Aug. 1896 to June 1898); Minister of Public Works (March–Oct. 1906 and in the subsequent Clemenceau Cabinet until July 1909); Minister of Justice from July 1909 until March 1913; prime minister from May 22 to Dec. 2 1913; Minister of State in the Painlevé Ministry during the World War, subsequently succeeding Ribot as Minister for Foreign Affairs; Minister of War Jan. 16 1921. His most notable political achievement was the manner in which he pushed through the Three Years' Service Bill, which was a response to German military preparations before the war of 1914. He was elected a member of the French Academy in 1918.

BARTON, CLARA (1821-1912), American philanthropist (*see* 3.452), died at Glen Echo, Md., April 12 1912. She is the only woman whose name has been taken by a post of the G.A.R.

See Mrs. Corra Bacon-Foster, *Clara Barton, Humanitarian* (1918), which outlines her career with extracts from records, letters, and contemporary papers.

BARTON, SIR EDMUND (1840–1920), Australian statesman and judge, was born at Sydney, N.S.W., Jan. 18 1840. He was educated at the Sydney grammar school and the university of Sydney, where he won many distinctions, and was called to the N.S.W bar in 1871, becoming Q.C. in 1889. At the age of 30 he entered the N.S.W. Legislature as representative for Sydney University, and remained a member of either the Assembly or the Legislative Council for many years. During 1883–7 he was Speaker of the Assembly and in 1889 and again in 1891 he was for a time Attorney General. In 1897, after the death of Sir Henry Parkes, he became senior representative for N.S.W. to the Federal Convention. He was a keen supporter of Federation and in 1900 led the delegation sent to London with the Australian Commonwealth bill. In 1901 he became the first Prime Minister of federated Australia, holding also the portfolio of External Affairs. His two years of office were much troubled by party strife. He had been a lifelong supporter of Preference, but his majority over Sir George Reid and the Free Traders was small and the Labour party held the balance. In 1903 he was glad to resign office and accept the appointment of Senior Puisne Judge of the High Court of Australia. In 1901 he was sworn of the Privy Council and in 1902 he was created G.C.M.G. He died suddenly at Medlow Bath, near Sydney, Jan. 6 1920. Known affectionately as the "Father of Australia," Edmund Barton inspired through his long career as a politician a deep personal devotion. His magnificent talents were used more for the advancement of his ideals and the help of his friends than in the service of his personal ambitions. Like a genial Dr. Johnson in conversation, he made easy captives of British statesmen on his visits to London. One of his sons was the first Rhodes scholar from N.S.W. to Oxford.

BARUCH, BERNARD MANNES (1870–), American financier, was born in Camden, S.C., Aug. 19 1870. He graduated from the College of the City of New York in 1889. For many years he was a member of the New York Stock Exchange but sold his seat in 1917. He first came into national prominence when appointed by President Wilson as a member of the advisory committee of the Council of National Defense in 1916, and after America's entrance into the World War he held many important positions. He was chairman of the Committee on Raw Materials, Minerals and Metals, and was in charge of purchases by the War Industries Board. He was also appointed a member of the commission in charge of all purchases made for the Allies. He became chairman of the War Industries Board in 1918 but resigned at the close of the year. In 1919 he was a member of the Supreme Economic Council of the Peace Conference in Paris and in the same year was appointed by President Wilson as a member of the Industrial Conference in Washington. He wrote *The Making of the Reparation and Economic Sections of the Treaty* (1920).

BASCOM, JOHN (1827–1911), American educationist and philosophical writer (*see* 3.458), died Oct. 3 1911 at Williamstown, Mass.

BASEBALL: *see* SPORTS AND GAMES.

BASHFORTH, FRANCIS (1819–1912), English mathematician, was born at Thurnscoe, Yorks., Jan. 8 1819. Second wrangler in 1843, he was elected a fellow of St. John's College, Cambridge; and having taken orders, he was rector of Minting, Lincs., from 1857 to 1908. His interest in ballistics led him to make a series of experiments between 1864 and 1880, upon which our present knowledge of air-resistance is founded (*see* 3.271). The Bashforth chronograph for recording the velocity of shot (*see* 6.303) was his invention, and he received a pension from the Government and a grant of £2,000 for his work. For some time he was professor of applied mathematics to the advanced class of artillery officers at Woolwich. He died at Woodhall Spa, Lincs., Feb. 12 1912.

BASSERMANN, ERNST (1854–1917), German politician and leader of the National Liberal party, was born June 26 1854 at Wolsag in the Black Forest. He began his career in 1880 as a lawyer at Mannheim. From 1885 to 1892 he was a deputy in the Baden Diet, and from 1893, with brief interruptions, a member of the Reichstag. In 1905 the National Liberal party elected him as president of the party. In the Reichstag he enjoyed a high reputation as a speaker, and he exercised an eminent influence on the course of politics. He died July 17 1917 at Mannheim.

BASTIAN, ADOLF (1826–1905), German ethnologist (*see* 3.500), died in 1905.

BATAILLE, FÉLIX HENRY (1872–). French poet and playwright, was born at Nîmes April 4 1872, and was educated at the lycée Henri IV. at Paris and the lycée Janson de Sailly. He brought out his first play, *La Belle au bois dormant*, in 1894 and his first volume of poetry, *La Chambre blanche*, in 1895. His dramatic work includes *La Lépreuse* (1896); *Ton Sang* and *L'Enchantement* (1900); *Le Masque* and *Resurrection* (1902); *Maman Colibri* (1904); *La Marche Nuptiale* (1905); *Poliche* (1906); *Les Flambeaux* (1912); *Le Phalène* (1913). Among his later poems may be mentioned *La Divine Tragédie* (1916) and *La Quadrature de l'Amour* (1920). *Notre Image*, in which Réjane made one of her last appearances, *Les Sœurs d'Amour* (1910), *L'Homme à la Rose* (1920) and *La Tendresse* (1921), are among his recent successful plays.

BATEMAN, KATE [MRS. CROWE] (1842–1917), American actress (*see* 3.508), died in London April 8 1917. She had since 1892 conducted a school of acting, appearing only rarely on the stage; but she played Lady Kew in *Colonel Newcome* at His Majesty's theatre, London, in 1906, the nurse in *Medea* at the Savoy theatre in 1907 and Kirjipa in *False Gods* at His Majesty's in 1909.

BATESON, WILLIAM (1861–), British biologist. was born at Whitby Aug. 8 1861, the son of the Rev. W. A. Bateson, some time master of St. John's College, Cambridge. He was educated at Rugby and St. John's College, Cambridge, and became famous for his biological investigations, which included important researches on Mendelism and the determination of sex. In 1894 he published *Materials for the Study of Variation*. In 1907 he gave the Silliman lecture at Yale University, from 1908 to 1909 was professor of biology at Cambridge, and in 1910 was appointed director of the John Innes Horticultural Institution at Merton Park, Surrey. From 1912 to 1914 he was Fullerian professor of physiology at the Royal Institution, and in 1914 was president of the British Association. He received the Darwin medal of the Royal Society, of which he was a fellow, in 1904. His other works include *Mendel's Principles of Heredity* (1902) and *Problems of Genetics* (1913), besides many short studies on biological subjects.

BAUER, GUSTAV (1870–), German Socialist, and first chancellor of the republican German Reich, was born Jan. 6 1870 at Darkehnen in East Prussia. At an early stage of his career he took up the secretarial work of the German Trades Unions movement and in 1908 became president of the general committee of the Trades Unions of Germany. Elected a member of the old Reichstag in 1912, he was appointed on Oct. 5 1918 Secretary of State for the Department of Labour in the Government of Prince Max of Baden, the last Government under the old régime. In Feb. 1919 he was appointed Minister of Labour in the republican Government of the German Reich and on June 21 of the same year president of the Ministry which was installed to accept the Peace Treaty of Versailles. The new constitution of the Reich having been enacted, the president of the Ministry resumed, in accordance with its provisions, the old title of chancellor (*Reichskanzler*) and Bauer was the first to hold this office under the republican régime. He remained chancellor until the Kapp *coup* of March 1920, when he fled with the president of the Reich, Ebert, and the rest of the Ministry to Dresden and afterwards to Stuttgart. On their return the Ministry was reconstructed and Bauer made way for the second republican chancellor, Hermann Müller, himself becoming for a brief period the Minister of the Treasury (*Reichsschatzminister*).

BAUER, OTTO (1881–), Austrian politician, was born Sept. 5 1881, the son of a Viennese manufacturer. He entered the faculty of jurisprudence at the university of Vienna, devoting himself especially to the study of economics, principally under Böhm-Bawerk. As a student he took an active part in the work of the Social Democratic party, and was early a zealous contributor to the *Arbeiter-Zeitung*. He served in the campaign of 1914, and was a prisoner of war in Russia from 1915 to 1917. After his return to Vienna he was elected a member of the committee of the Social Democratic party, and became the leader of the increasingly influential Left group. After the revolution he succeeded, in Nov. 1918, his master Viktor Adler as State Secretary for Foreign Affairs. In this capacity he energetically supported the idea of the union of German Austria with Germany. During the peace negotiations at St. Germain in July 1919 he retired from his office, but remained until Oct. a member of the Socialization Commission. He subsequently became one of the most conspicuous leaders of the Social Democratic party in the Constituent National Assembly and in the National Parliament (*Nationalrat*), his speeches dealing mainly with financial questions, such as the tax on capital, and foreign affairs.

His works are: *Die Nationalitätenfrage und die Sozialdemokratie* (1908); *Die Teuerung* (1911); *Balkankrieg und Deutsche Weltpolitik* (1912); *Die russische Revolution und das europäische Proletariat* (1917); *Bolschewismus oder Sozialdemokratie?* (1920).

BAVARIA, a territory and free state of Germany (*see* 3.543).—The pop. of Bavaria, with which Coburg had voluntarily united in 1920, was, according to the census of 1919, 7,140,333; without Coburg 7,066,024, in 1910 6,887,291.

Political History, 1910–21.—The two last years of the life of the Prince-Regent Luitpold were characterized by an intensification of internal political conflicts which arose from the increasing estrangement between the Podewils Government and the majority of the Diet (*Landtag*) consisting of the Catholic Centre party.

In the summer of 1910 Minister of Finance von Pfaff had succeeded without much difficulty in passing an important measure of taxation reform by the vote of the non-Socialist parties and had thus been able to introduce a general income tax in order to consolidate the financial position of the country. But the resistance with which, in the following year, the Minister of Communications, von Frauendorfer, and the whole Cabinet met the demand of the Centre for the suppression of the South German Railway Men's Union, on the ground of its alleged Socialist tendencies, soon led to an open conflict between the majority and the Government. On Nov. 8 1911 the majority of the Finance Committee of the Diet refused to discuss with Frauendorfer the vote for the estimates of his department. The Government, in the hope of solving the conflict and relaxing the strain of the internal situation, induced the aged Regent to order the dissolution of the Diet. This was done on Nov. 14. For the elections which took place on Feb. 5 1912, the Liberal parties, the Social Democrats and the Bavarian Farmers' League (*Bayerischer Bauernbund*) concluded an alliance the effect of which was that only one candidate was set up by the allied parties in each constituency against the candidate of the Centre. The Podewils Cabinet resigned on the day of the elections in order to give the Crown a free hand according to the results. These results did not fulfil expectations. The Centre returned an absolute majority in the Diet, although their allies, the Conservatives, came back with much less than half their former strength. The Liberals, the Social Democrats and the Farmers' League gained seats, but not enough to overthrow the Clerical-Conservative majority.

The Prince-Regent entrusted the university professor, Dr. Baron von Hertling (afterwards Chancellor of the German Empire 1917–8), who also sat in the Reichstag in Berlin as a member of the Catholic Centre party, with the formation of a ministry. Baron von Hertling acted in the sense of his commission; he selected two of the leading members of the Centre and filled the remaining posts with politically colourless officials. The hope that the elections would have relieved the strained condition of internal politics was not at first fulfilled. On the contrary the controversy about the treatment of the South German Railway Men's Union was further embittered by the issue of an ordinance which demanded from the workers on the railways the signature of a paper certifying their loyalty; and the issue of a secret ordinance on toleration of the exercise of priestly functions by members of the Jesuit Order, which was still forbidden by a Law of the empire, roused the opposition to the Hertling Ministry to increased violence. By a decision of the Federal Council of Nov. 28 1912 disavowing this secret edict of the Bavarian Government, the controversy about the Jesuits was eliminated, but new subjects of conflict soon arose.

On Dec. 12 1912 Prince-Regent Luitpold died in his ninety-second year. His son Louis assumed the regency, and took the oath to the constitution on Dec. 21.

The movement for ending the regency (which had lasted since 1886 and was due to the insanity of King Otto) and conferring the royal dignity upon the Regent, coincided in point of time with the bill introduced by the Government for increasing the Civil List from 4·2 to 5·4 million marks (£270,000). After protracted debates, by which the internal conflicts of the country were intensified, the Diet on Oct. 30 1913 passed, by a majority of 122 against 27 Social Democratic votes, an amendment to the constitution ending the regency and enabling the Prince-Regent, Louis, to assume royal authority. After the Upper Chamber had given its assent, Prince Louis issued a proclamation on Nov. 5 announcing his assumption of the crown. The demand for the increase in the Civil List was granted by the Diet on Nov. 21 against a minority of 50 Liberals and Social Democrats.

The War Period.—The truce to party politics (*Burgfrieden*), which had completely silenced political conflicts at the outbreak of the war, continued as an after-effect, to mitigate them. In 1915 the edict regarding the declaration of loyalty to be signed by the railway-men was withdrawn; in 1916 the Minister of the Interior, von Soden, who was widely attacked on the ground of his agrarian food policy, was replaced by the former Minister of the Interior, von Brettreich, while Gen. von Hellingrath replaced Gen. von Kress as Minister of War. In the later years of the war, when discontent due to the oppressive war burdens was accompanied by increasingly powerful efforts to carry domestic reform, resolutions of the Social Democrats in favour of proportional representation, a parliamentary régime, and the abolition of the Upper Chamber were repeatedly rejected by the majority of the Chamber of Deputies; but the Government promised at least to introduce a bill for the overdue reform of the Upper House (*Kammer der Reichsräte*). On Nov. 10 1917 Count (as he had now become) Hertling resigned the presidency of the Ministry in order to assume the office of chancellor of the empire. He was succeeded by Herr von Dandl, hitherto chief of the Civil Cabinet of the King.

The imminence of the revolution, a consequence of the discontent excited by the increasing burdens imposed by the war, made itself felt as far back as Jan. 1918 in Bavaria as in the empire. The band of Independent Socialists led by the Social Democratic newspaper editor, Kurt Eisner, did not succeed, it is true, in launching a general strike of munition workers, but there were demonstrations in Nürnberg and Fürth and also in Munich, leading in some cases to street conflicts. Eisner himself and a number of his partisans were arrested and kept in custody with a view to their trial. He was set at liberty only by the political amnesty which the Government of Prince Max

of Baden issued for the whole empire. In the summer and autumn of the year 1918 there were instances of insubordination in one or two Bavarian garrison towns among troops who were being sent off to relieve regiments at the front. Such breaches of discipline indicated opposition to the war in the army and among the population. Eisner was set up by the Independent Socialists in Oct. 1918 as their candidate at a by-election for the Reichstag in the constituency of Munich. At a series of election meetings he advocated the idea of a violent rising of the masses with the object of rapidly ending the war and overthrowing the ruling authorities.

After the War.—On Nov. 7 the Social Democratic party and the Independent Socialists organized a mass-meeting on the Theresienwiese, a large park in Munich, in favour of peace; it was attended by about 150,000 workmen and passed off without incident. After the close of the meeting, however, Eisner with his adherents marched through the city, called out the soldiers from the barracks, occupied the guard-house of the royal residence, and formed on the same evening a provisional Workmen's and Soldiers' Council which held its first sitting in the building of the Diet. It sat all night, and a proclamation issued in the early hours of the morning announced the deposition of the dynasty and the conversion of Bavaria into a republic. As the soldiers, with the exception of the officers, were almost unanimously in sympathy with the action of Eisner, and as the working classes and the rural peasantry led by the two Farmers' Leaguers, Joseph and Karl Gandorfer, made common cause with him, no serious resistance was offered. The King had left Munich on the evening of Nov. 7 and taken refuge in the castle of Anif in Salzburg. On Nov. 8 the Workmen's and Soldiers' Council in Munich elected a new revolutionary Government with Eisner at its head as Minister-President. Other members of the new Ministry, in addition to Majority and Independent Socialists, were Prof. Jaffé as Minister of Finance and the former Minister von Frauendorfer as Minister of Communications. The new Government issued on Nov. 15 an elaborate programme, and Eisner himself endeavoured by the appointment of the pacifist Prof. Dr. Foerster as diplomatic envoy to Berne and by wireless messages to the Allies to promote the conclusion of peace on tolerable conditions. He encountered vigorous opposition in the Bavarian press, including Socialist journals, on account of these proceedings and above all on account of his hostility to the Government of the Commissaries of the People which had just been formed in Berlin. There was a powerful movement in favour of instituting general elections for the Constituent Bavarian National Assembly, but Eisner only yielded to it on Dec. 5. The elections were fixed for Jan. 12 1919. On Jan. 6 1919 the revolutionary Government issued an ordinance setting up a provisional constitution, which conferred upon the Ministry supreme executive powers and a veto upon decisions of the Diet. In the event of the veto's being employed, the vote of the people was to give the final decision. The revolutionary Government was, moreover, to exercise legislative powers until the enactment of a definitive constitution. The elections of Jan. 12 resulted in a powerful displacement of political power towards the Left. The Bavarian People's Party (*Volkspartei*), which had constituted itself on an independent basis as the successor of the Catholic Centre party in Bavaria, won 66 seats, the German People's Party (former National Liberals) and the German Nationalists (old Conservatives) nine seats, the Farmers' League 15 seats, the Democrats 25 seats, and the Social Democrats 62 seats.

The National Assembly was convoked for Feb. 21. Meanwhile the masses had become more and more extremist in the Bavarian capital. There were repeated demonstrations which led to collisions and riots. Although Eisner made great efforts to prevent bloodshed, he could not make up his mind to dissociate himself unequivocally from the extremist elements which were coquetting with Bolshevist ideas. On Feb. 21, when on his way to the Diet in order to inform it of the resignation of the revolutionary Government, and to invite it to elect a new ministry, he was shot dead by Count Arco, a former officer. Before the Assembly could adopt any attitude towards this assassination, it was broken up by the infuriated adherents of Eisner. Men armed with pistols stormed the House and the Social Democratic Minister of the Interior, Auer, who had been wrongly accused of participation in the conspiracy against Eisner, was severely wounded by a shot in the chest, while one deputy and one official were mortally wounded. There followed a period of lawlessness when everyone did as he pleased, since there was no organ of any kind for exercising the sovereign powers of State. The Congress of Councils (Soviets), which met after the assassination of Eisner, arrogated to itself supreme power, and it was only after protracted negotiations between this Congress and the Social Democratic party, which had identified itself with the opposition in the provinces to the usurpation of the Munich Congress, that it was possible to form a new Government. The Social Democratic deputy, Hoffmann, who had been Minister of Education under Eisner, undertook the presidency of the Ministry; the Government was composed of Independent (extreme) and Majority (moderate) Socialists. The National Assembly met for one brief sitting and transferred the power of legislation to the Ministry until law and order could be reëstablished. Meanwhile things did not settle down; on the contrary, the situation in the capital became more and more confused. As the Government did not consider that it possessed in Munich the power to carry through its will, it left the city two days before the proclamation of the Councils (Soviet) Republic and betook itself to Northern Bavaria, where it hoped to find support among those sections of the population whose opinions were Democratic. In Munich a dictatorship of a number of extremists, under the influence of Bolshevists such as Levin and Leviné-Nissen, held sway for four weeks under the name of Councils Republic. The fugitive Socialist Government took up its residence at Bamberg, where the National Assembly also met. With the military support of the Reich, action with Prussian, Württemberg and Bavarian troops was initiated against Munich and culminated in the capture of the capital and the suppression of the extremist insurrection after severe fighting on May 1, 2, and 3.

The final phase of the struggle was characterized by some acts of barbarity, such as the murder of a number of hostages, including a Countess Westarp, in a cellar by the Soviet extremists. Unfortunately in the suppression of the "Red Terror" grave excesses were likewise perpetrated by the other side. There were numerous summary executions and arbitrary arrests, so that in some instances persons who were entirely innocent lost their lives or were put in prison. Northern Bavaria had taken no part whatever in the movement. The Diet remained for the time being at Bamberg. The Government, after the Independent Socialists had left it, was converted into a coalition by the inclusion of two members of the Democratic and two of the Bavarian (Catholic) People's party, with Hoffmann as Minister-President. It submitted to the Diet the draft of a constitution which gave effect to the ideas of parliamentary democracy and which also provided for the exercise of the referendum under certain conditions. A number of other measures for completing the edifice of the democratic State were submitted, and the whole session of the Diet at Bamberg was occupied with the consideration of these. The constitution (see below), the Teachers and Schools law and a number of other important laws were passed. The new constitution bears the date of Aug. 14 1919.

It was only in the late autumn when order had been restored throughout the whole country that the Government and the Diet returned to Munich. In order to prevent the recurrence of a situation like that which had existed under the Councils (Soviet) Republic, the Government had caused so-called *Einwohnerwehren* (volunteer defense forces of the inhabitants) to be formed; in these armed bodies the citizens who took their stand upon the constitution united on a democratic basis for the protection of public order and for the defense of the constitution against popular *emeutes*. They elected their own leaders

and endeavoured to act as private organizations without any connexion with regular military bodies. The idea of the *Einwohnerwehren* rapidly took a firm hold, especially among the non-Socialist (*bürgerlich*) section of the population, so that these bands of volunteers developed into a powerful and well-armed volunteer organization. The Kapp *Putsch* which had resulted in a change of Government in the Reich, also produced certain effects in Bavaria. Although the movement did not secure any open adherents there, it brought about a domestic crisis in the course of which the Socialist ministers left the Cabinet. A Provincial Government president, von Kahr, was elected president of the Ministry, and the members of the Cabinet were taken from the adherents of the Bavarian (Catholic) People's party, the Democrats and the Liberal Farmers' League (*Bauernbund*). The elections for the Diet, which took place simultaneously with those for the Reichstag on June 6 1920, exhibited a natural reaction after the hardships which the country had had to suffer from the excesses of the extremist groups during the 18 months following upon the revolution; there was a great increase in the strength of the non-Socialist (*bürgerlich*) parties. Only 27 Social Democrats, 22 members of the Independent Socialist party and two Communists were elected, while on the other hand 108 members of the non-Socialist parties were returned. Among the latter the Democrats had, however, lost many seats to the German Nationalists (the old Conservatives) and to the German People's party (the old National Liberals). Herr von Kahr was again entrusted with the formation of a Cabinet; he selected one Farmers' Leaguer, one German Nationalist (Conservative) and one Democrat, and filled the other ministerial posts with members of the Bavarian People's party and with officials who were in sympathy with that party. He received powerful support from a party organization in the country which was the rival of the Farmers' League, the Catholic Peasants' Union (*Bauernverein*), at the head of which was the gifted and popular Dr. Heim, who has been called "the uncrowned King of Bavaria." On the whole the country remained free from domestic disturbances. On the other hand the necessity of disarming and disbanding the *Einwohnerwehren* in accordance with the Treaty of Versailles led to protracted and difficult negotiations with the Government of the Reich and to an exceedingly critical situation for the Kahr Ministry in Bavaria itself, as that Ministry had made the maintenance of the *Einwohnerwehren* one of the principal planks in its platform.

In consequence of the ultimatum of the Allied Powers the situation with regard to the disarmament of the *Einwohnerwehren* became acute as between the Reich and Bavaria in May 1921. Direct diplomatic representations were made to the Bavarian Government; for France, in spite of a provision in the new constitution of the Reich (Art. 78), had accredited a minister to Bavaria, while Great Britain had ultimately sent a diplomatic consul. Herr von Kahr was finally constrained to announce that in agreement with the leaders of the *Einwohnerwehr* the Bavarian Government were prepared to make the sacrifice of disarmament. The Government had previously been vigorously pressed in this sense by the Opposition and in particular by the Independent Socialists. Their leader, Gareis, an able young man in his thirty-second year, was assassinated, doubtless by the hand of a reactionary, on his way home from a meeting on the evening of June 9 1921, an event which once more threatened to arouse the insurrectionary fury of the industrial masses.

Altogether the position of Bavaria within the Reich remained in many respects a source of perplexity in 1921. Much would depend upon the degree of success with which the Central Government (of the Reich) in Berlin might be able to grapple with problems of home, and more especially of foreign policy in carrying out the provisions of the Treaty of Versailles.

(O. S.)

The New Constitution.—During the night between Nov. 7 and Nov. 8 1918, before the imperial régime had been overthrown in Berlin (Nov. 9), the revolution broke out at Munich. The House of Wittelsbach was expelled. The Independent Socialist, Kurt Eisner, one of the most remarkable personalities of the revolution, put himself at the head of the revolutionary Government. It was contemplated that a newly elected Diet (*Landtag*) should provide the new republic of Bavaria with a basis of legality by means of a constitution. The electoral regulations issued with this object on Dec. 9 1918 conferred the franchise upon all Bavarians, without distinction of sex, who had reached their twentieth year. In order, however, to safeguard the results of the revolution Eisner's Government promulgated before the elections for the Diet a provisional fundamental law of the State for the "Socialist Republic of Bavaria," and this fundamental law provided for the establishment of parliamentary Government. The Diet was to have met on Feb. 21 1919. On that day Eisner was assassinated; the disorders which followed prevented the Diet from taking in hand at once the preparation of the definitive constitution. What the Diet adopted in the first instance was once more a provisional "Fundamental Law of the State," which corresponded in essentials with the first provisional law and came into force on April 2 1919. Thereafter the fresh revolution of the Communists, which had been threatening since the assassination of Eisner, broke out. Under the leadership of Russian Bolsheviks, the "Councils Republic" of Bavaria was set up. By May 1 the domination of the Communists was again at an end. The Diet could reassemble, though, at first, not in Munich. On May 28 1919, the draft of the text of a constitution for the "Free State of Bavaria" was submitted to the Diet by the Hoffmann Ministry. After detailed consideration the Constitution was voted and came into force on Aug. 14 1919.

The constitution starts from the assumption that Bavaria continues to be a state within the German Reich, although it has had to cede a great part of its former rights to the Reich. This conception was still more strongly emphasized in Eisner's provisional "Fundamental Law of the State" than in the constitution which was finally adopted; for Eisner's fundamental law was headed by the declaration, "Bavaria is a member of the United States of Germany (the German Reich)." Eisner indeed vigorously defended the conception of federalism in opposition to the view that Germany had by the revolution become a single, united state (*Einheitsstaat*). On the publication of the first draft of the constitution of the Reich, which was essentially unitarist, Eisner brought about a conference of representatives of the German states, at which the South German states succeeded in securing the institution of a permanent "Committee of the States." This committee or delegation coöperated in the legislation which followed, particularly in the preparation of the new constitution of the Reich. The *Reichsrat*, the federative organ of the Reich, originated in this committee. It is true that Bavaria, notwithstanding its resistance, had not only to give up its "Reserved Rights,"[1] but also to acquiesce in considerable limitations of its independence. It had to cede to the Reich the control of foreign policy, of the army and of communications, in particular the railways; it may not maintain in foreign countries either legations or consulates of its own. It has also been subjected to considerable restrictions in its economic policy by the Reich, as economic legislation falls within the competence of the latter, while the finance legislation of the Reich has appropriated almost all the sources of taxation. All the greater were the efforts made in the Bavarian constitution to give effect in its provisions to the residue of sovereignty which has been left to the territories (the Free States) in the Reich. It goes so far in this regard that some of its provisions can scarcely be brought into harmony with the constitution of the Reich. The form of the State is prescribed for the territories by the constitution of the Reich.

Bavaria accordingly is, like the Reich, a "Free State" (republic). The powers of the State (sovereignty) proceed from the people. It is in the Parliament, the Diet (*Landtag*), that the powers of the State are actually vested. Bavaria is thus, like the Reich, a "representative democracy," but it is a democracy without "the separation of the powers"; for it does not possess an organ for the executive with rights equal to those of the Diet—a president. The ministry is appointed by the Diet and is answerable to it; a minister must at once resign when the Diet expresses its want of confidence in him. The rights of the Diet are, however, limited by the fact that it is left open to the people itself to exercise the powers of the State directly. This may take place if, by a "demand of the people" (the initiative), the popular decision (*Volksentscheidung*) regarding a law or regarding the dissolution of the Diet is brought into action. In order to bring about a decision of this character, a formal pro-

[1] *Reservatrechte*, which were secured for it under the constitution of the Hohenzollern Empire.

posal, which must have been supported by at least one-tenth of the citizens possessing the franchise, is requisite. If it be a case of an alteration of the constitution or of the dissolution of the Diet, the support of one-fifth of the electorate is required. This right of direct coöperation by the people is intended to be a substitute for the "balance of powers" which is lacking in the constitution. To this extent the Bavarian constitution, as indeed the constitutions of the other German territories and that of the Reich, contains an element which signifies "direct democracy."

The Diet consists of a single Chamber. There is no Upper House. All men and women who have completed their twentieth year have the franchise. They elect the deputies by secret ballot on the basis of proportional representation, arranged so that there is a deputy for every 40,000 inhabitants. The details of electoral procedure are fixed by a separate electoral law. Only citizens of Bavaria who have completed their twenty-fifth year are eligible.

The ministry is appointed by the Diet in the following manner. First the minister-president is elected. He submits a list of the candidates whom he proposes for the other ministerial posts, and the ministers are appointed with the assent of the Diet. It is not requisite that ministers should be members of the Diet. The real organ of the executive is the ministry as a whole, but it is at the same time, as follows from what has been said, dependent upon the Diet. The ministry adopts its decisions by majority. The minister-president presides over the whole ministry and has a casting vote when the voting is equally divided. The ministry distributes the affairs of the state among the different ministerial departments and makes the appointments to the most important administrative posts. It issues general ordinances for the conduct of administration and decides upon the legislative measures which are to be submitted in the name of the Government to the Diet. If a minister in the exercise of his office has designedly or by gross negligence infringed the constitution or one of the laws, he may be impeached by resolution of the Diet before the Court of Jurisdiction in State Affairs (*Staatsgerichtshof*). The penalty for ministers who are found guilty is dismissal from office. The majority of the Court of Jurisdiction in State Affairs consists of members of the Diet; the minority is composed of official judges.

Legislation is conducted in the following manner: The Diet votes upon the bills which are initiated among its own members or are laid before it by the popular initiative (*Volksbegehren*). An appeal to the popular decision (*Volksentscheidung*), or referendum, on a legislative measure arises (1) when the Diet rejects a popular demand (*Volksbegehren*) for the enactment of a law; or (2) when the Diet passes a law without a popular demand for it having been presented, and when thereupon an appeal is made to the popular decision (*Volksentscheidung*) either in consequence of a resolution of the ministry or in consequence of a popular demand (*Volksbegehren*) for the referendum. There is, however, an important class of laws which are exempt from the referendum, in particular laws relating to the budget or relating to taxes or excise duties, and laws dealing with the salaries of officials. There is likewise no referendum in the case of a law which the Diet has declared to be urgent.

The estimates are annually fixed by the Diet by legislation. But, in order to preclude reckless finance on the part of the Diet, the constitution prescribes that, on the demand of the ministry, there shall be a second reading of those financial resolutions which have the effect of increasing the amount of the items or of introducing fresh items of expenditure. At the second time of voting such resolutions a majority of two-thirds of the members present is requisite. Once the measure is voted, it is dispatched by the president of the Diet and the whole ministry, and is promulgated. (W. v. B.)

BAZIN, RENÉ (1853-), French novelist and man of letters (*see* 3.561), produced two further novels, *Davidée Birot* (1912) and *Gingolph abandonné* (1914), as well as a volume of travel sketches, *Nord-Sud Amérique, etc.* (1913) in the pre-war period. After 1914 he published two volumes of war sketches, *Pages religieuses* (1915) and *Aujourd'hui et demain* (1916), as well as two novels, *La Closerie de Champdolent* (1917) and *Les nouveaux Oberlé* (1919).

BEACH, REX (1877-), American writer, was born at Atwood, Mich., Sept. 1 1877. He was educated at Rollins College, Fla. (1891–6), the Chicago College of Law (1896-7), and Kent College of Law, Chicago (1899-1900).

His tales of adventure include *Pardners* (1905); *The Spoilers* (1906, also dramatized); *The Barrier* (1907); *The Silver Horde* (1909); *Going Some* (1910, also dramatized); *The Ne'er-do-Well* (1911); *The Net* (1912); *The Iron Trail* (1913); *The Auction Block* (1914); *Heart of the Sunset* (1915); *Rainbow's End* (1916); *The Crimson Gardenia, and Other Tales of Adventure* (1916); *Laughing Bill Hyde and Other Stories* (1917); *Too Fat to Fight* (1919); *Oh, Shoot!* (1921).

BEATTY, DAVID BEATTY, 1st Earl (1871-), British admiral, was born in Ireland in 1871, the son of Capt. D. L. Beatty, 4th Hussars, of Borodale. He was not, as so many naval officers are, predestined to his profession by family association or tradition, which in his case took its tone chiefly from the army and the hunting-field; his father was a well-known figure in the Leicestershire world of the 'eighties and 'nineties. That David alone of the family went into the navy was largely a matter of accident, and his own choice at the age of 13, when he was sent to the Royal Naval Academy at Gosport, can certainly have had little to do with it. Yet within 35 years of that date he had run through the whole gamut of naval possibilities, including those attained only rarely by naval men of any age—Commander-in-Chief of the Grand Fleet, Admiral-of-the-Fleet, and First Sea Lord—to say nothing of an earldom, the thanks of Parliament, the O.M., and the Lord Rectorship of Edinburgh University. His sea service combined the maximum of variety with a minimum of mere routine. As midshipman he served in the Mediterranean flagship "Alexandra" and with the training squadron in the "Ruby." He was sub-lieutenant in the "Nile" and the yacht "Victoria and Albert." His six years of service as lieutenant were passed in the "Ruby," "Camperdown" and "Trafalgar"; in the Portsmouth destroyer flotilla, and in the Nile gunboats. His service there and in the battles of Atbara and Omdurman won him his commandership, and in that rank he served in the "Barfleur." The Boxer rising gave him another opportunity of active service; he was wounded while in command of a shore party, when his dash and leadership won him further promotion, and he became captain at the record age of twenty-nine. From 1900 to 1910 he was in command successively of the cruisers "Juno," "Arrogant" and "Suffolk," and the battleship "Queen." In the naval manœuvres of 1912 he flew in the "Aboukir" his flag as rear-admiral, a rank which he had attained 24 years from the day the boy of 13 had entered Gosport Academy.

Even up to this point his career establishes a record in the history of the navy. It was, in a sense, so far as the navy was concerned, an obscure career, unhelped by "influence," unknown to the public, undistinguished by the kind of fame attained by the passing of examinations. It was remarkable only by its brilliant rapidity. What he had done he had done by himself, and he had come under no personal influence, with the possible exception of that of Lord Kitchener as Sirdar, that had particularly inspired or moulded him. He was never at the top of any of the lists of his rank, but generally near the bottom, from which he would leap, by sheer merit of service, to a similar humble position at the bottom of the next list, thus passing on the ladder hosts of officers who were laboriously climbing by the routine of seniority and the death or promotion of those above them. To make legal his promotion to flag rank in 1910 a special Order in Council had to be passed, as he had not served the statutory time in command of a ship at sea. His two Admiralty appointments afforded him brief but valuable experience. While still a captain he had acted for about a year as naval adviser to the War Council; and under Mr. Churchill he became naval secretary to the First Lord. In this capacity he assisted at the conference held at Malta in 1912 when the decision was made to reconstitute the Mediterranean fleet by replacing the older battleships by a smaller but more modern force of battle cruisers. In 1913 he was appointed to the command of the First Battle Cruiser Squadron, the fastest and most powerful scouting force ever launched, and hoisted his flag in the "Lion" (March 1).

From this brief outline of his service career it will be observed that Beatty escaped two things. By seizing every opportunity for fighting service he avoided that long period of drudgery in big ships which had for some time been recognized as having a deadening effect on the fighting spirit and initiative of naval officers. Similarly he was equally successful in avoiding long periods of shore service at the Admiralty which, valuable as they may be as a training in administrative work, do not tend to develop the entirely different set of qualities demanded of an officer in high command afloat in time of war. Of administrative work in the large sense Beatty had practically no experience at all when he hoisted his flag in the "Lion" and pro-

ceeded to train the newly formed squadron. In some ways it was an advantage. He came to this vital task with an original and untrammelled view of its essential objects, with an instinct for warfare developed in actual fighting, and with a mind undulled by subservience to that long grind of routine which is the inevitable avenue to flag rank except for the fortunate few who, like him, can gain early promotion for fighting services. Throughout his career, when Beatty was given the choice of decoration or other distinction as a reward for such service, he always chose promotion. He had an instinctive certainty that war with Germany would come in his time; and in so far as it lay in his power to shape his career, he shaped it so that he should be in a position to take a leading hand when the hour struck. As it was, with all the brilliant rapidity of his advancement, the war came just a little too soon to give him at the outset, and at the most vital moment, the position of commander-in-chief, which no doubt would have come to him almost as a matter of course if he had had a little longer in which to prove his undoubted qualifications for that post. When he did succeed to it the pioneer work of fleet organization had been done by Sir John Jellicoe, and the policy governing the use of the Grand Fleet as a strategic weapon had been, for good or ill, definitely established.

When the World War broke out, Beatty, although long marked by an intelligent few as certain to achieve distinction, was practically unknown to the navy at large. The routine Home fleet service in which officers get to know each other intimately had claimed little of his time; and when he took command of the battle cruisers even Lord Fisher had never met him. But a very few weeks of war service revealed his quality as a leader. In the action of the Heligoland Bight (Aug. 28 1914), a reconnaissance of light craft in which the battle cruisers were acting in support of Commodores Keyes and Tyrwhitt, Sir David Beatty exhibited his remarkable instinct for being at the right place at the right moment. Partly owing to faulty Admiralty dispositions the British light craft, after the first object of the action had been achieved, were in danger of being cut off when Adml. Beatty, acting not so much on information as on his intuitive sense of the position, turned back through a submarine-infested area and arrived just in time to save them and sink every German ship in the immediate neighbourhood. Then and throughout the war his battle cruisers were the spearhead of the British naval forces. In a score of operations of which, as they did not result in contact with the enemy, history takes no note, and in the two which developed into fleet actions, Beatty, in his famous flagship the "Lion," was the leading spirit and pivot of the fighting forces. A true disciple of Nelson, he was a rebel against the official conception of British strategy that, provided the enemy were properly contained, his destruction was a kind of luxury that might be indulged in only on condition that the containing force was not unduly risked. Beatty, on the other hand, was inspired with the spirit of attack. He had unique qualities as a leader which made men willing to follow him anywhere, and to achieve the impossible; but apart from his dash and courage he showed consummate skill and caution in dealing with the new hidden elements which have placed so great a power in the hands of the defensive in modern naval warfare. At the battle of the Dogger Bank (Jan. 24 1915) he chased the enemy for three hours, inflicting such severe punishment that the "Blücher" was sunk and the "Seydlitz" and "Derfflinger" and "Moltke" were in full flight, the two former in a battered condition, when the "Lion," which as head of the pursuing line had received heavy punishment, was put out of action, and the command devolved on Rear-Adml. Sir Archibald Moore. This officer, whose flag was flying in the "New Zealand," gave no orders during the vital 40 minutes following the "Lion's" disablement. Adml. Beatty's signals to "keep nearer to the enemy" were either missed or misunderstood by the ships immediately following him, with the result that touch with the German battle cruisers was lost, and what was on the point of becoming a complete victory was left merely as an indecisive castigation of the enemy. The facts of this action, which had not been officially made public up to the spring of 1921, were first given at that date in Mr. Filson Young's *With the Battle Cruisers*, containing a very full account of the battle, with track charts and the actual text and times of the signals made.[1]

Beatty's brilliant handling of the battle cruisers in the battle of Jutland is discussed in the article on that action (*see* JUTLAND, BATTLE OF). Some months later (Dec. 1916) he succeeded Sir John Jellicoe as Commander-in-Chief of the Grand Fleet, in which capacity he received the surrender of the German fleet on Nov. 21 1918. He was raised to the peerage in 1919 as Earl Beatty, Visct. Borodale of Borodale, Baron Beatty of the North Sea, receiving the thanks of Parliament and £100,000. At the same time he was awarded the G.C.B., the O.M. and other honours and decorations. In 1919 he became First Sea Lord, and immediately set in motion measures for a reorganization of the naval staff on lines which would give the younger school of naval thought and experience a chance to make itself felt. He attended at Washington, D.C., in 1921 the Conference on the Limitation of Armament.

The following estimate of Lord Beatty was given, in the book referred to, by Mr. Filson Young, who had served on his staff in the "Lion."

> "One who has served him and observed him closely in the stress of war may at least bear this testimony to his conduct in the chapter of his life which is already over: that in everything that he did or attempted he showed forth in himself and evoked in others the fighting spirit that made England invincible in the past. The common view of him as a dashing leader trusting largely to luck, which so much endears a man to the ordinary English mind, is singularly untrue. It was not the mere instinct of the hunting-field, strong as it was in him, that brought him to the head of the Navy. His caution and his sense of responsibility were just as remarkable as his enterprise; but they were never allowed to obscure or dominate the fighting spirit. Perhaps the greatest tribute one can pay to him and to the Navy is to say that in the qualities in which he proved supreme he was not exceptional, but typical; and it was because he was a product of the modern Navy and contained in himself all its most characteristic qualities, that the Navy would have trusted and followed him anywhere."

Lord Beatty married in 1901 Ethel, daughter of Marshall Field, sen., of Chicago; of his two sons the elder, Viscount Borodale, was in 1921 a cadet in the Royal Navy. (F. Y.)

BEAUCHAMP, WILLIAM LYGON, 7TH EARL (1872–), English politician, was born in London Feb. 20 1872, the eldest son of the 6th earl. He was educated at Eton and Christ Church, Oxford, and afterwards entered public life as a Liberal. In 1891 he succeeded his father in the title. He was mayor of Worcester from 1895 to 1896, and in 1897 became a member of the London School Board. In 1899 he was appointed governor of N.S.W., but in 1901 returned to England. In 1907 he became lord steward of the royal household, and in 1910 entered Mr. Asquith's Cabinet as first commissioner of works and lord president of the council, retaining the latter post on the reconstruction of the Government in 1914. He received the Order of the Garter in 1914, and retired in 1915. Lord Beauchamp was from 1906 to 1907 captain of the Honourable Corps of Gentlemen-at-Arms, and in 1913 was made lord warden of the Cinque Ports. He married in 1902 Lady Lettice Grosvenor, daughter of Earl Grosvenor and sister of the 2nd Duke of Westminster.

BEAVERBROOK, WILLIAM MAXWELL AITKEN, 1ST BARON (1879–), British politician, was born at Newcastle, New Brunswick, on May 25 1879, the son of the Rev. William Aitken, Presbyterian minister of Newcastle. He was educated at Newcastle, and afterwards went into business, where he had a very successful career as a financier. Having made

[1] The Financial Secretary to the Admiralty answered in the affirmative a question asked in the House of Commons on May 4 1921 by Visct. Curzon as to whether the account given in this book might be taken as correct. Its publication then relieved Adml. Beatty of any responsibility for the somewhat misleading version originally issued by the Admiralty of his own dispatch after the battle.

a large fortune at a comparatively early age, he came to England in 1910, and stood successfully for the House of Commons as Unionist candidate for Ashton-under-Lyne. He was from the first an intimate friend and adviser of Mr. Bonar Law when the latter became the Unionist leader. In 1911 he was knighted. In 1915 he went to France with the Canadian expeditionary force as "Eye-Witness," and in 1916 became the representative of the Canadian Government at the front, also doing valuable propaganda work. He was created a baronet in June 1916, and the same year was raised to the peerage. In 1917 he was appointed officer in charge of the Canadian war records, and in 1918 entered the Government as Chancellor of the Duchy of Lancaster in succession to Lord Cawley and director of the Ministry of Information in succession to Sir Edward Carson, but resigned in Oct. of the same year. Lord Beaverbrook became one of the chief proprietors of the London *Daily Express*, and in 1916–7 published *Canada in Flanders*.

BEBEL, FERDINAND AUGUST (1840–1913), German socialist (*see* 3.601). During Bebel's last years his views regarding the revision of the Social Democratic programme underwent a considerable change; he ultimately favoured revision in the sense of coöperation with non-Socialist political parties in democratic reforms. In the Reichstag he continued to oppose with great energy the world policy and the naval expansion with which William II. and his successive chancellors were identified. At the same time he guarded himself against the reproach of favouring a policy of non-resistance to foreign aggression, and on one occasion declared that he would be the first to shoulder his rifle if Germany were invaded. His attitude towards imperial and autocratic Russia was throughout uncompromising. He denounced the complaisance of Prince Bülow's Government towards the Russian Government in respect of the treatment of Russian political refugees, and it would hardly be too much to say that he would have welcomed a rupture with Russia on almost any ground. His influence in this regard powerfully contributed to foster those sentiments in the Social Democratic party which led it, a year after his death, to acclaim the declaration of war against Russia on Aug. 1 1914. In internal affairs he particularly distinguished himself by his denunciation of the maltreatment of soldiers by officers and still more frequently by non-commissioned officers. His efforts in this matter had received great encouragement when Albert of Saxony (1828–1902) issued an edict dealing with the maltreatment of soldiers in the Saxon contingent, thus cutting the ground from under the feet of the Imperial Government, which had persistently attempted to deny or to explain away the cases adduced by Bebel. Bebel had amassed a fortune—some £30,000, it is said—from the proceeds of his writings, and this was increased by a legacy of some £20,000 left him, curiously enough, by an officer who had profited by his advice in a disciplinary case in which the officer had once been involved. He owned a villa on the Lake of Zürich where in later life he spent a great part of the year. One of his last public appearances was at an International Peace Conference at Bern in 1913. He died at a sanatorium at Passuggin, Switzerland, on Aug. 13 1913.

BECK, FRIEDRICH, Count (1830–1920), Austrian general, was born at Freiburg im Breisgau, and entered the army in 1848. He distinguished himself as chief-of-staff of an infantry division at Magenta, and in 1863 was made personal aide-de-camp to the Emperor. He held this position, with that of adjutant-general and chief of the imperial military chancery until 1881, winning the Emperor's confidence and exercising the greatest influence on all military questions. In 1866 he acted as the Emperor's confidential agent at the headquarters of Field-Marshal Benedek, before and after the battle of Königgrätz, and his advice was of great importance, though it was not always followed. In 1878 he was entrusted with a similar mission to the commander-in-chief of the troops operating in Bosnia. In 1882 he was made chief of the general staff of the Imperial and Royal army, an exalted position which he occupied till 1906. Not only was his advice listened to in military affairs, but he frequently exercised great influence on important political and personal questions, gaining a great reputation throughout the monarchy as one of its most influential men. His clear judgment and practical common-sense enabled him to see and judge men and things from a purely objective standpoint. He was retired at the age of 77, with every possible sign of honour, and was appointed commander of the Imperial Guard. He took no part in the World War, and died in Feb. 1920. (A. K.)

BECKWITH, J(AMES) CARROLL (1852–1917), American portrait painter (*see* 3.610*). He exhibited at St. Louis in 1904 "The Nautilus" and a portrait of Mrs. Beckwith. Yale, Johns Hopkins, and West Point possess examples of his works, and the New York Public Library has a collection of his crayon and pencil drawings. He died in New York, Oct. 24 1917.

BEECHAM, SIR THOMAS, 2nd Bart. (1879–), English musical conductor, was born April 29 1879, son of Sir Joseph Beecham, 1st bart. (1848–1916), who had made a large fortune at St. Helens, Lancs., as proprietor of "Beecham's Pills." Young Beecham was educated at Rossall and for a time at Wadham College, Oxford. His father was keenly interested in music and had given financial support to a number of musical enterprises in the North of England, where the son acquired considerable experience as a conductor. In 1905 he gave his first concert in London with the Queen's Hall orchestra. A little later he founded first the New Symphony orchestra and next the Beecham orchestra, both first-rate concerns. In 1909 he appeared in London as opera conductor, and in Feb. of the following year the Beecham Opera Co., consisting entirely of English-speaking singers, was inaugurated. The season was started at Covent Garden in the following year when among other operas produced for the first time in London were Strauss's *Elektra* (Feb. 1910), Delius's *Romeo and Juliet in the Village* and Debussy's *L'Enfant Prodigue*. In the same year there was a further season at His Majesty's theatre during which Strauss's *Feuersnot* was given, its London *première*. Further London seasons followed in later years, all with decided artistic success. These led up to the great climax when in 1913 the Beecham season of opera and ballet at Covent Garden included the production of Strauss's *Rosenkavalier* and *The Legend of Joseph*. Later in the same year there was a magnificent season at Drury Lane of Russian opera and ballet, made famous not only by the splendour of the productions of Russian opera in the vernacular, which in all probability would never otherwise have been heard in London, but by the remarkable singing and still more remarkable acting of Shaliapin, who then made his first appearance in England. During the second and third years of the World War there were Beecham seasons of opera at the Shaftesbury and Aldwych theatres, when pronounced success was achieved by performances of *Valkyrie* and *Tristan and Isolde* sung in English. Beecham's own version of Bach's cantata *Phoebus and Pan* was given at the latter theatre. In 1917 the Beecham Opera Co. were once more at Drury Lane, and in 1920 Beecham organized a somewhat ill-starred cosmopolitan "grand" season at Covent Garden, during which Puccini's so-called triptych, *Il Tabarro*, *Suor Angelica* and *Gianni Schicchi*, was given for the first time in Great Britain. From 1915 to 1918 Beecham was conductor of the Royal Philharmonic Society, whose very existence during the World War he practically guaranteed. In 1916 he was knighted, and shortly afterwards he succeeded to his father's baronetcy. The lavish expenditure of his private fortune upon opera in English ultimately led to financial embarrassments which in 1920–1 necessitated the suspension of his musical activities.

BEECHING, HENRY CHARLES (1859–1919), English divine and author (*see* 3.640), who was appointed dean of Norwich in 1911, died at Norwich Feb. 25 1919.

BEERBOHM, MAX (1872–), English writer and caricaturist, was born in London Aug. 24 1872, the son of Julius Beerbohm and Eliza Draper, and half-brother of the actor, Sir Herbert Beerbohm Tree. He was educated at Charterhouse and Merton College, Oxford, and afterwards became well known as a contributor to the *Yellow Book* and dramatic

* *These figures indicate the volume and page number of the previous article.*

critic on the *Saturday Review.* He married in 1910 Miss Florence Kahn, of Memphis, Tennessee, and afterwards took up his residence at Rapallo, Italy. His published writings include *The Works of Max Beerbohm,* containing the famous essay on George IV., and also *A Defence of Cosmetics* (1896); *The Happy Hypocrite* (1897); *More* (1899); *Zuleika Dobson* (1911); *A Christmas Garland* (1912); *Seven Men* (1919), and *And Even Now* (1920). He also contributed to and edited the *Life* of Sir Herbert Beerbohm Tree, published in 1920. He is well known by his caricatures, of which exhibitions have been held in London at the Carfax Gallery (1906) and the Leicester Galleries (1911, 1913, 1921). In 1917, a Modern Loan Exhibition at the Grosvenor Galleries included a group of 15 caricatures entitled "Rossetti and His Friends." Many of his caricatures have been published in *Caricatures of Twenty-five Gentlemen* (1896); *The Second Childhood of John Bull* (1901); *The Poets' Corner* (1904); *A Book of Caricatures* (1907); *Fifty Caricatures* (1913). His delicate and incisive satire has found its best material in the peculiarities of individuals in every section of society. Movements he almost invariably typifies by some well-known personality. Pledged to no party, his friends have occasioned some of his most characteristic work, notably the series dealing with the New English Art Club and with Mr. Balfour. Like Forain and Steinlein in his detachment, he lacks their universality; and complete appreciation of his art implies an intimate knowledge of current affairs. As a draughtsman he is not faultless, and sometimes resorts to the veriest conventions; but his freedom of line, feeling for delicate colour and sense of design are remarkable, especially in his later work. (W. G. C.)

BEERE, MRS. BERNARD [FANNY MARY] (1856–1915), English actress, was born at Norwich Oct. 5 1856. She was the daughter of Wilby Whitehead and was trained for the stage by Herman Vezin, appearing first in the Opéra Comique, London, in 1877. Later she played Emilia in *Othello* and various old English comedy parts at the St. James's theatre. In 1883 she was engaged by the Bancrofts to play leading parts in *Fédora* and other dramas at the Haymarket. In 1891 she played Lady Teazle in Charles Wyndham's production of *School for Scandal,* and two years later Mrs. Arbuthnot with Herbert Tree in Oscar Wilde's *A Woman of No Importance.* She was three times married, but for stage purposes retained the name of her second husband. In 1900 she married Mr. A. C. S. Olivier. She died in London March 25 1915.

BEESLY, EDWARD SPENCER (1831–1915), English positivist (*see* 3.644), died at St. Leonards-on-Sea July 7 1915.

BEGAS, REINHOLD (1831–1911), German sculptor (*see* 3.652), died Aug. 3 1911.

BEHAVIOURISM.—In the earlier article on INSTINCT (*see* 14.648) and also, though perhaps less obviously, in that on INTELLIGENCE IN ANIMALS (*see* 14.680), the stress was laid on behaviour. In later years attention has been turned more and more to what has become known in this connexion as "behaviourism." What then *is* behaviourism? It has features in common with pragmatism and with neo-realism. It is however (as is the case with these other 'isms) somewhat difficult to define. If we seek to elicit from the writings of this or that behaviourist a clear statement of the doctrine he champions or accepts, we find not a little divergence of opinion. And perhaps each would remind us that J. J. Thomson has spoken of science as a policy rather than a creed. What then is their common policy? One may reply without much fear of misinterpreting their aim: A resolute application of radical empiricism in the scientific interpretation of all behaviour and conduct.

In this interpretation a good deal turns on the relation of behaviour to consciousness, in some sense of this word. "Critics of behaviourism," says Weiss (1918), "do not recognize clearly enough that the term 'consciousness' varies in its meaning with nearly every person who uses it. There is no generally accepted definition or description; and the fact that psychologists and philosophers have been unable to reach an agreement is one of the conditions which has precipitated behaviourism." As to behaviourists themselves he tells us that, thus far, they have agreed that the most convenient procedure is not to use it at all. It needs, however, but little acquaintance with their writings to realize that, so far is this from being a matter of common agreement among them, there is much discussion of the sense in which the adjective "conscious" as applied to behaviour is to be understood. Here again opinions differ. But let us put the question in a rather different form. Let us ask: In what sense is the word "consciousness" to be rejected by every behaviourist? As to the answer to this question there is a far larger measure of agreement.

In 1904 William James asked the question: Does consciousness exist? His reply was that it does not exist as an hypostatized entity with the unique privilege of activity, but that it does exist as a function. In its negative aspect his answer excludes "the hypothesis of trans-empirical reality," *i.e.* that from which proceeds what is sometimes spoken of as "an alien influx into nature." The transcendental *Ego* of the philosophies, he urges, shows how "the spiritual principle attenuates itself to a thoroughly ghostly condition." And he says roundly: "I believe that 'consciousness,' when once it has evaporated to this estate of pure diaphaneity, is on the point of disappearing altogether. Those who still cling to it are clinging to a mere echo, the faint rumor left behind by the disappearing 'soul' upon the air of philosophy." There is no activity of consciousness in this sense. "The healthy thing for philosophy is to leave off grubbing underground (in the realm of the trans-empirical) for what effects effectuation or what makes action act." Activity in an empirical sense there is in plenty. It is change in progress referred to some "storm-centre" of change. It is change intrinsic to some system and not merely imposed upon it from without. But there is for scientific treatment no activity of a trans-empirical entity which may be regarded as the source of such change. When therefore a behaviourist says that "we need a psychology of human conduct to supplant the psychology of consciousness" (G. A. Tawney 1911), that which he seeks to supplant is a psychology which invokes what James spoke of as trans-empirical agency. It is probably not going too far to say that this marks a distinctive feature of behaviourist interpretation.

It should here be added that though this may with some confidence be said to be a distinctive feature of behaviourist interpretation it does not follow that if this be accepted one may infer that a writer who accepts it is to be ranked as a behaviourist. It is, for example, fully endorsed by Howard C. Warren in his *Human Psychology* (1920). But he says: "The behaviourist contends that the data of consciousness should be ruled out of science altogether because they are not causal factors. This narrowing of the scope of science has not justified itself up to the present. Self-observation has proved more useful than the study of behaviour in investigating the phenomena of human mental life." It is questionable, however, whether all who label themselves behaviourists do contend that the data of consciousness should be ruled out altogether. R. M. Yerkes would not agree that this is so in animal psychology. And E. B. Holt, though he sails under the behaviourist flag in his *Freudian Wish,* assuredly does not rule out consciousness.

Let us broaden our outlook. If we extend the use of the word "behaviour" so as to include physical events, their modern treatment tends more and more towards behaviourism. "Our sole task," says A. N. Whitehead, "is to exhibit in one system the characters and inter-relations of all that is observed. Our attitude towards nature is purely behaviouristic so far as concerns the formulation of physical concepts." His attitude towards organic events and their mental concomitants may be different. But his rejection of any "bifurcation of nature" and his polemic against a doctrine of "psychic additions" (*Concept of Nature,* ch. ii.) is in line with the neo-realistic attitude of those behaviourists who deal with organic life. His percipient event is the homologue of the organism under the treatment of radical behaviourism. Neither the one nor the other stands in need of any "psychic addition" *ab extra* for the adequate interpretation of the facts. Each is set in a field

which for the physicist is a field of acceleration, and for the biologist and psychologist is a field of the environment to which the organism responds *more suo*. The business of science in each case is to formulate an answer to the question: Given such a field, having what may be called varying density, what happens therein? One does not enquire: What makes that which happens so happen? At least one does not ask any such question in a trans-empirical sense. To do so is to "grub underground for what makes action act." But on such terms where does psychology come in? One has here to realize that there are two schools of behaviourists. According to one school the study of conduct is to supplant that of consciousness through so-called methods of introspection. According to the other school such study is to give new value and direction to psychology and thus involves not the abandoning but a redefining of the concept of consciousness. Here alliance is sought with those whom they regard as in spirit, if not in name, one with them in aim. Behaviourists of this latter school, while still rejecting consciousness as a trans-empirical agent, and thus avoiding all taint of animistic interpretation, all interaction of mind and body as disparate entities, all so-called parallelism and the like, none the less accept consciousness as an empirical function. What does this mean? It is connected with what is spoken of as the relational view of consciousness, and thus has points of contact with the relational view of space-time. Indeed F. J. E. Woodbridge (1905) says that we should use the expression "in consciousness" in a manner like unto that in which we use the expression "in space" or "in time"; and just as we do not ask if space and time, as such, affect things causally, so too we should not raise the question of the causal efficiency of consciousness.
